In some ways "chunk" is a misleading term for the phenomenon. The word calls to mind something discrete and hard-edged, whereas the very essence of the phenomenon is the way we can give it new shapes and new characteristics, and the way conceptual fragments interpenetrate each other in long-term memory. A chunk might better be conceived of, metaphorically, as a pointer to information in long-term memory, and the information it retrieves as a cloud with a dense core and ill-defined edges. The mind can store an enormous number of such clouds, each overlapping many others.

This "cloudiness"—the way any one concept evokes a series of others—is a source of great efficiency in human communication; it is what lets us get the drift of a person's remarks without having all the implications spelled out. But it can also be a source of confusion. Consider the following examples, some showing efficiency, some opening the way for confusion.

- My teenage daughter, nervously trying to pour conditioner into a narrow-necked bottle, says, "This isn't going to work." But she doesn't hesitate in her pouring, and the job is completed without mishap. Her words, her inflections, and her actions have communicated a whole web of concepts to me (and perhaps to herself) which are far indeed from what she actually said.

- A boss comes out of an inner office, puts a small stack of typewritten pages on the secretary's desk, says, "There aren't enough copies," and goes back into the office. The secretary might tell you the boss had said to make more copies. The boss might agree. Both are working from assumptions that go unarticulated but not from what the boss actually said. (In addition you, the reader, may have thought of the boss as being male and the secretary as being female—another unarticulated assumption.)

- In a cognitive science lecture a speaker reads aloud the following sentences: "Mary heard the ice cream truck coming down the street. She remembered her birthday money and ran into the house." Those in the audience conclude that the sentences are about a little girl who is going to buy some ice cream; the speaker notes that this conclusion is based on inference, not on anything explicitly stated.

Cognitive scientists apply a variety of terms—"networks," "schemata," "scripts"—to the unspoken contexts into which we set pieces of information. The last example in particular makes clear how eager we are to build such contexts. Neither we nor the lecturer's audience had any obvious need to construct any story at all from those two sentences about Mary, yet nearly everyone does. We form chunks about any information that interests us, and (heuristics again) we tend to believe our chunks are valid until the evidence that they are not is overwhelming. And we form our chunks right away, as the information is coming in: there is no nonsense about waiting for a sufficiency of evidence. Each new bit of data is evaluated in light of the chunks already on hand, all of which are treated as at least arguably valid. We find it far more difficult to evaluate existing chunks on the basis of a new piece of data.

When we need to get through large quantities of data, when we do not have to move too far from an experiential reference point, when a "best possible" answer is sufficient (and these criteria are met most of the time), chunking can be amazingly effective. The approach works in contexts far more complicated than might be expected, as is indicated by the experiments with chess players conducted by Simon and others.

a. Another point this little excerpt brings to light is the degree of linguistic imprecision we can tolerate, particularly when we are dealing with spoken language

What are the hallmarks of a first-class chess player? Not, it seems, the ability to look further ahead in the game or to evaluate a larger number of possible moves; the master's approach is not much more extensive in these respects than the beginner's. What distinguishes the master and the grandmaster is the store of chess patterns built up in long-term memory over years of competition and study. Simon estimates that a first-class player will have 50,000 of these patterns to call on—by no means a small number, but orders of magnitude less than the theoretical possibilities that flow from any given position. The expert can use them to drastically reduce the number of choices he must consider at any point in a game, with the result that he often hits on an effective move with such speed that the observer attributes it to pure intuition.

So formidable is this ability (which is little more than heuristics and chunking) that humans were able to keep ahead of chess-playing computers for longer than most experts in the field predicted. When a computer that could beat nearly every human was developed, it did not duplicate the chunking approach but instead performed a brute-force search of all possible moves. Computers still are far inferior to humans in their ability to narrow the field heuristically, but they can now explore the whole field of chess moves in the time normally allowed between moves.

None of this emphasis on the importance of a' store of chunks is to deny the importance of individual talent in chess or any other field of mental activity. There is nothing that says you will automatically become a grandmaster if you simply lodge 50,000 or more chess patterns in your long-term memory. But you apparently cannot become a grandmaster *without* such a store of chunks, and cognitive scientists argue that a network of similar size and complexity is essential for effective work in most fields. Developing an adequate network is laborious and time-consuming, and there apparently are no shortcuts. Edison's aphorism about genius being two percent inspiration and 98 percent perspiration is buttressed by J.R. Hayes's discovery that almost without exception, classical composers did not start producing first-rate work until they were at least 10 years into their careers.[a]

By now we can speak in some detail about how the centipede runs—i.e., how humans do mental work. We still are speaking in highly schematic terms, the picture that emerges is exceedingly complex, and there is a great deal that cannot be addressed intelligently at all. But I think we can draw some illuminating conclusions, often humbling and heartening at the same time:

- Heuristics—non-random exploration that uses experience and inference to narrow the field of possibilities—loom large in the development of each individual and are deeply ingrained in all of us (particularly when we are doing something we consider important). Combined with the chunking speed of short-term memory, the heuristic approach is a powerful way to deal with large amounts of information and a poorly defined problem space.

- But there is always a tradeoff between range and precision. The more of the problem space you try to explore—and the "space," being conceptual rather than truly spatial, can have any number of dimensions—the harder it is to achieve a useful degree of specificity. Talent and experience can often reduce the conflict between the need for range and the need for precision, but they cannot eliminate it. We almost always end up satisficing.

- We are compulsive, in our need to chunk, to put information into a context. The context we start with heavily conditions the way we receive a new piece of information. We chunk so rapidly that "the problem," whatever it is, often

a. Mozart, who springs to mind as the obvious exception, turns out to have been a late bloomer by this standard. Hayes used a criterion for "first-rate work" that seems terribly unscientific at first: he decided that a composition qualified if five or more recordings of it were listed in the Schwann catalogue. The idea looks a bit more sensible at second glance, and in any case the consistency of Hayes's findings is striking. He obtained data for 76 composers and found only three—Satie, Shostakovich, and Paganini—who produced even one such piece within 10 years of the time they began studying music intensively.

has been sharply delimited by the time we begin manipulating it in working memory.

- Skill in a given area of mental activity involves both talent and time, the latter to build the extensive network of chunks that appears to be a prerequisite for really first-class work. The effort typically extends over several years; the investment may not pay off for a decade.

- Although the conceptual network formed through years of experience may make an individual a more skillful problem-solver, it can also make him or her less open to unusual ideas or information—a phenomenon sometimes termed "hardening of the categories." The conservative bias of the heuristic approach—the tendency we all share of looking to past experience for guidance—makes it easy for an old hand to argue an anomaly out of the way. In fact the old hand is likely to be right nearly all the time; experience usually does work as a model. But what about the situation when "nearly all the time" isn't good enough? Morton Hunt recounts an instance of a computer proving better than the staff of a mental hospital at predicting which patients were going to attempt suicide.

- Finally, the mental processes outlined in this section seem certain to remain the processes of choice for all of us. With all their drawbacks, heuristics remain arguably the most efficient way to narrow a large field of possibilities; and efficient or not, we like it.

So far, however, the findings we have discussed are little more than abstractions; they lack an operational context for the DI. And for good reason: the directorate is basically a writing organization, and cognitive science can hardly be relevant to our work until it addresses the main thing we do. As the section that follows makes clear, the focus quickly becomes operational as soon as the ideas accumulated so far are applied to the issue of writing.

III. Speaking and Writing, News and Knowledge

When people who deal with cognitive activity discuss the means we use to communicate with each other, they tend to refer to something they call "language." Unless they specify otherwise they generally mean spoken language, not writing. They discuss written language much less frequently, and when they do there sometimes is even a hint that they consider it less important than speech. Few have focused on it as a subject of research. This seems strange, since not only do these people make their living by the written word, they would have little hope of fully articulating their thoughts unless they had writing available as a tool.

Speech is the natural medium of decisionmaking....The essence of the decision process is oral.

What accounts for this phenomenon? First, it simply may not have occurred to them that there is a useful distinction to be made between speech and writing. Second, writing is a much more opaque process than speech and thus is harder to analyze. A speaker literally is making up what he says as he goes along, and it is relatively easy to gain insights into his cognitive activity by observing what he says and how he says it. The writing process is more convoluted and internal, and it is harder to get even a general notion of what is happening.

But I think there is a third reason, one that has great import for the way the directorate goes about its cognitive work. In some ways those who treat writing as less important than speech are right. The spoken word is the dominant (usually the only) linguistic medium in those preschool years when our basic conceptual furniture is being established, and I would argue that it is the medium to which we all, even the compulsive writers among us, naturally turn when an issue engages our emotions. Above all, I think, speech is the natural medium of decisionmaking. In my own family, when we are doing something hard like

picking a college for a high-schooler, we will write some transactional letters, and we will do some reading to gain information. But the essence of the decision process is oral. If this is true for someone like me—someone whose whole career has been involved with writing—how much truer must it be for those who do not see writing as a way of life. This latter group obviously includes most of humanity; it specifically includes nearly all of those for whom our written products are intended. I do not conclude from this that the directorate should get out of the writing business. I do not think we can do our work in any other medium. But if it can be shown that the cognitive processes involved in writing and speech differ in important respects, then I think it follows that the relationship between our writing-based work and our speech-oriented consumers deserves close attention.

Here are some of the ways in which writing and speech differ:

- With speech, much of the communication takes place in ways that do *not* involve words: in gesture, in tone of voice, in the larger context surrounding the exchange. Speech is a complex audio-visual event, and the implications we draw—the chunks we form—are derived from a whole network of signals. With writing there is nothing but the words on the paper. The result may be as rich as with speech—nobody would accuse a Shakespeare sonnet of lacking richness—but the resources used are far narrower.

- Writing calls for a sharper focus of attention on the part of both producer and receiver. When you and I are conversing, we both can attend to several other things—watching the passing crowd, worrying about some aspect of work, waving away a passing insect—and still keep the thread of our discourse. If I am writing or reading I must concentrate on the text; these other activities are likely to register as distractions.

- The pace and pattern of chunking is very different in the two modes. With speech, one word or phrase quickly supersedes the last, and the listener cannot stop to ponder any of them. What he ponders is the chunk he forms from his perception of everything the speaker is saying, and he is not likely to ponder even that very intensively. He does have the opportunity to ask the speaker about what he has heard (an opportunity almost never available to a reader), but he rarely does so; the spoken medium has enormous forward momentum. In compensation, speech uses a much narrower set of verbal formulae than writing. It relies heavily on extralinguistic cues, and by and large it is more closely tied to a larger context that helps keep the participants from straying too far from a common understanding. In the written medium, by contrast, the reader can chunk more or less at his own pace. He can always recheck his conclusion against the text, but he has little recourse beyond that. All the signals a writer can hope to send must be in the written words.

- A reader is dealing with a finished product: the production process has been essentially private. A listener is participating in a transaction that is still in progress, a transaction that is quintessentially social.

- Partly because of the factors listed so far, writing is capable of more breadth and more precision than speech. Neither complex ideas nor complex organizations would be possible without writing. My own impression is that even in this television-dominated era, people attach more solidity and permanence to something written than to something spoken. Perhaps we have an ingrained sense that the products of speech are more ephemeral than the products of writing. But to achieve this aura of permanence writing sacrifices a sense of immediacy. A writer tends to speak with the voice of an observer, not a participant.

Thus it appears that a person working with speech is doing markedly different things than a person working with writing. This is true whether the person is acting as a producer or a consumer. Further, because everyone works at times with speech—whereas not everyone works in any

comprehensive sense with writing—speech is a far more general medium of exchange. I suspect that most people tend to transfer what they have learned from writing into the spoken mode: usually that is where information gets used.

The transfer from writing to speech is made easier because the chunks I form after reading your text are most unlikely to take in all the detail you have laid out. The only way to work back toward your degree of detail is to reread your text, and I will not take in everything even if I do so (much of what you want to say is not even set down explicitly). If I do not go back I will operate with the chunks as they currently exist in my mind (and as they combine with other chunks, at least equally powerful, that my mind was working with before). This does not necessarily mean that my new set of chunks will be either less complex or less valid than yours; it does suggest that what I glean from your prose will be altered and simplified. Because of the simplification, what I have gleaned will be easily available for me to use in the speech mode. I will be all the more inclined to use it in this way if I am oriented toward decision and action, either generally or in this particular situation. If such is my inclination, I probably will do just what I did when the issue of sending children to college arose: view the text mainly in terms of what seems useful and ignore the rest.

The distinction I am making between writing-based and speech-based cognitive processes is illumined by Walker Percy's distinction between news and knowledge. To introduce his thesis Percy asks us to imagine an isolated island inhabited by people with a well-developed culture. On the shores of this island arrive thousands of sealed bottles, each bottle containing a single assertion like the following:

- E=MC2.
- A war party is approaching from Bora Bora.
- The dream symbol, house and balcony, usually represents a woman.
- Being comprises essence and existence.
- In 1943 the Russians murdered 10,000 Polish officers in the Katyn Forest.
- Tears, idle tears, I know not what they mean.
- There is fresh water in the next cove.
- Chicago is on the Hudson River or Chicago is not on the Hudson River.

An islander, Percy avers, might experiment with various ways of organizing these messages, but in the end would put each of them into one of two categories. The first category would include all the scientific and formal statements, all the generalizations, and also all the poetry and art. Producers of such statements are alike in their

> *withdrawal from the ordinary affairs of life to university, laboratory, studio, mountain eyrie, where they write sentences to which other men assent (or refuse to assent), saying, "Yes, this is indeed how things are."*

The second category would include statements that are significant

> *precisely insofar as the reader is caught up in the affairs and in the life of the island and insofar as he has not withdrawn into laboratory or seminar room.*

The statements about the Bora Bora war party and the water in the next cove would be obvious candidates for this category. The categories are neither hermetic nor unchanging. The statement about the Katyn massacre might be in either. The first category Percy calls knowledge; the second, news.[a]

Percy continues that not only are there two categories of information, they are read from two different postures, there are two different kinds of verifying procedures, and there are two different kinds of response:

- *Nature of the sentence*. Knowledge can in theory be arrived at "anywhere by anyone and

a. Percy, *The Message in the Bottle*, 119–39.

at any time"; news involves a nonrecurring event or state of affairs which bears on the life of the recipient.

- *Posture of the reader*. The reader of a piece of knowledge stands "outside and over against the world;" the reader of a piece of news is receiving information relevant to his specific situation.

- *Scale of Evaluation*. We judge knowledge according to the degree it achieves generality; we judge news according to its relevance to our own predicament.

- *Canons of acceptance*. We verify knowledge either experimentally or in light of past experience. News is "neither deducible, repeatable, nor otherwise confirmable *at the point of hearing*." We react to it on the basis of its relevance to our predicament, the credentials of the newsbearer (according to Percy, "a piece of news requires that there be a newsbearer"), and its plausibility.

- *Response of the reader*. A person receiving a piece of knowledge will assent to it or reject it; a person receiving a piece of news will take action in line with his evaluation of the news. (And, I would add, the receiver of a piece of news is more immediately concerned than the reader of a piece of knowledge with the correctness of the information.)

Obviously, I am building toward an assertion that the DI tends to deal in knowledge and our customers are interested mainly in news; and furthermore that there are correlations between news and the cognitive processes involved in speech on the one hand, and between knowledge and the cognitive processes involved in writing on the other. Equally obviously, the reality is not that simple, and the correlations are not exact. Not only does it demean our consumers to imply that they have little interest in knowledge as Percy defines it, but the distinction between news and knowledge, never airtight, has become increasingly problematic over time. With the information explosion and the widespread acceptance of the notion that knowledge is power (or to be more consistent with Percy's terminology, the notion that control over news is a source of power), speech- and action-oriented people have become ever more eager to scan knowledge-purveying documents for their news value. Moreover, the scope and depth of what such individuals are expected to know has expanded greatly. In both senses the potential domain of news has grown and has come to include regions that might in the past have been left to knowledge.

The boundaries get fuzzed in other ways. If I have discovered a new way to look at a problem, the discovery is likely to have the feel of news for me. But I may decide I have to use a knowledge-based mode to explain it. Perhaps, if I come from a scholarly environment, I believe knowledge has higher status than news. Or perhaps I do not think I can do justice to my discovery in a news-based mode—and if news, like speech, has a limited capacity to cope with complexity and my discovery is complex, my belief may have some validity. The recipient probably will duly register the resulting product as knowledge and may miss the sense of discovery altogether.

Finally, the material the DI deals with usually can fit under either heading, as was the case with the sentence about the Katyn massacre. A statement about the boiling point of water clearly is knowledge, and a statement about a fire that has just broken out in my office clearly is news; a statement about a balance-of-payments problem or a festering insurgency or a restive legislature could be either and is probably both. None of the latter statements is likely to have a high level of generality, none is likely to be easily verifiable under the canons of acceptance applicable to knowledge, and all are likely to involve the news-type question, "What (if anything) should the United States do?"

I still would argue, however, that when all is said and done the analytic work of the directorate fits more naturally on the knowledge side of the line and is inseparable from writing; whereas our consumers tend to look for news and to be more

comfortable with speech. I think this is one way of stating a basic challenge facing the directorate.[a]

I find it impossible to avoid the conclusion that we will do our work better if we include elements of speech and news. I also think that if we produce something that sounds like speech, it will tend to sound like news as well. I am not saying we should make our writing read like spoken English; the canons of speech and writing differ too greatly for that. But I do think we should aim for prose that has a conversational ring. How one does this is largely a matter of individual style, but some suggestions may be possible. Speech specializes in short sentences, it shies away from complex constructions, it uses short words (especially Anglo-Saxon ones), and it is peppered with verbs. Modelling prose around these characteristics—not inflexibly, not burdened by the specious claim that the result will inevitably be Dick-and-Jane (or perhaps Hemingway) prose—will, I think, help writing sound a little more like speech.

But don't you thereby rob yourself of conceptual complexity? Is it possible to lay out difficult ideas in conversational prose? All I can say is, it's been done. Whatever one thinks of Robert Pirsig's *Zen and the Art of Motorcycle Maintenance* in terms of substance, it does present some tough philosophical concepts in a palatable enough way to make the best-seller lists. The same is true of Hofstader's *Godel, Escher, Bach*. There is, in fact, a tradition of heavyweight conversational prose dating back as far as St. Paul and Plato. So at least in theory the idea is feasible. I would also urge all writers to ask themselves the following question: the idea may have been hard to clothe in words and get down on the page properly, but now that it is there, does it seem quite so complicated? Perhaps so; on the other hand, perhaps not. If the latter, perhaps putting it into more conversational language would not be too difficult.

This approach would nonetheless pose several problems. What I have called heavyweight conversational prose differs markedly in style from that usually produced by the directorate, and I think the differences arise from factors other than the DI's stylistic conventions and variations in individual writing skill. The most notable difference is that all the writers I cited as examples make extensive use of the first and second persons. This is a natural tendency when one is being conversational; one almost inevitably tries to personify the newsbearer and the recipient. I found in writing this essay that giving in to the tendency has a liberating effect.

A writer can forgo the first person singular and still be conversational— fortunately for the directorate, since the message-bearer for the news we write is a collective labeled "CIA," which can call itself "we" but never "I." The tendency to personify would persist, however. Even without the first person singular, I suspect the directorate's prose would take on a more individualistic cast. Moreover, a person writing in this mode is likely to assume a more actively persuasive tone and to risk crossing the line between persuasion and argumentativeness. These considerations lead me to believe that a turn toward conversational prose would add to the stress of the review and (perhaps even more) the coordination processes. I also think it is worth asking whether the structure would really be willing to tolerate a higher individuality quotient in the papers it produces.

I do not believe any substantial move would be made toward a greater news/speech content without tradeoffs such as these. They probably could be managed, if only because such changes in institutional style would have to come gradually, with large amounts of satisficing at every stage. But I do think such issues would have to be anticipated.

a. I also believe it is one factor making for turbulence in the flow of the review process. A reviewer, alive to the desires of the consumer, is likely to be looking for something resembling news/speech, whereas the writer will worry that the nuances and precision that can be conveyed only through knowledge/writing will be lost. What is pedestrian or convoluted to one is detailed and circumstantial to the other.

IV. Writing Schemes and Cognitive Overload

Only the original writer can impart a conversational tone to a draft, of course; it cannot be edited in later. Yet this essay has suggested that a writer is not likely to get his ideas articulated with the precision they require unless he works in a knowledge/writing mode, and that knowledge/writing is not inherently conversational. This implies that the writer would have to rework his prose even after the ideas had been articulated—a prospect few writers would relish. But putting the issue in these terms overstates the added burden and misstates the way it would be felt. The writing process is extraordinarily convoluted, and all writers constantly shift from one aspect of the problem to another. In this juggling act there is no question of deciding what you are going to say and then deciding how you are going to say it; writers—good writers in particular—work on all aspects of their problem virtually from beginning to end. If Flower and Hayes are correct, moreover, good writers represent this problem to themselves as a "complex speech act"; the conversational element is already present to some degree.

The writer does not decide what his ideas are and then decide how to communicate them; internal and external communication are of a piece.

Looking at the writing process as a whole will illuminate these notions. A writer is trying to accomplish two quite different things: to define what his ideas are by clothing them in words, and to communicate those ideas to others. Such is the nature of writing that the two goals are inextricably intertwined. To repeat, the writer does not decide what his ideas are and then decide how to communicate them; internal and external communication are of a piece. The complexity of this operation is one source of "cognitive overload." Another source is that as he writes, the writer is creating a datum—a malleable entity outside the mind that grows out of the mind's internal workings. The datum acts as an extension of working memory; the writer now has available a dependable array of chunks that is not limited by what working memory can attend to. Yet working memory itself is as tiny as ever, and it cannot keep track of all aspects of the datum unless it shifts constantly from one aspect to another.

Skilled writers use a variety of means to reduce the overload. For example, they satisfice. "Not the right word but what the hell," said one subject of an oral-protocol experiment at Carnegie-Mellon. The context indicates he was implying that the word was good enough for now and could be polished when working memory had been cleared of other demands. Or they draw on patterns stored in long-term memory, just as the skilled chess player does. (The patterns must be appropriate, of course. A new arrival in the DI is likely to discover that many patterns learned earlier no longer work, and building a store of, say, 50,000 patterns that do work takes time.) According to Flower and Hayes, perhaps the most effective technique of all is what they call "planning"—but the term takes on a different meaning in this context. It does not simply equate with outlining. In fact, Flower and Hayes found in their analysis of oral protocols that few people made use of outlines or other structured techniques. "Planning" might better be thought of as developing heuristic strategies and monitoring those strategies.

Flower and Hayes suggest that there are three different sorts of strategies:

- At the highest level, a strategy *To Do*. This is the rhetorical problem the writer sets out for himself: "Write a current intelligence article shooting down this coup report"; "Turn out something that will get through the review process without too much hassle"; "Write a paper that shows how stupid the conventional wisdom is"; "Set down this new idea."

- Next, a strategy *To Say*. This is essentially a content plan—the points to be gotten across to the reader. One can jot down informal notes or work up a detailed outline. "A plan *To Say* is

essentially a scale model of the final product. Perhaps that is why it has been so widely and vigorously taught, often to the exclusion of any other kind of planning." The plan *To Say* is subordinate to the plan *To Do*.

- Finally, and coordinate with the strategy *To Say*, a strategy *To Compose*. This category includes the interaction between ideas and the developing text. It includes short-range mental notes like "I'll write down a bunch of ideas and connect them later." or "A point I will want to make someplace is that…"

Failure to go beyond a plan *To Say* is a good route to ineffective prose. Skilled writers are adept at using all three strategies in conjunction with each other, checking and rechecking one against another and monitoring how each is working. They spend less time considering plans *To Say* than do novices, and more time considering the overall assignment (plans *To Do*) and the rhetorical challenges involved (plans *To Compose*). Flower and Hayes add: "Moreover, as they write, they continue to develop their image of the reader, the situation, and their own goals with increasing detail and specificity."

A striking aspect of the approach of skilled writers is the frequency with which they think about how they are affecting the reader. A comparison between two writers of different skill levels is shown in the table below. The expert spoke of the way he represented the audience and the assignment more than twice as often as the novice did, and he spoke of goals vis-a-vis the audience 11 times, whereas the novice did not consider this aspect of the problem at all. By contrast, the two were quite similar in the frequency with which they addressed questions of text and meaning. Hayes and Flower go on to assert that being alive to the audience and other aspects of the rhetorical context enriches substantive content as well. With a good writer three fifths of the new ideas grew out of thoughts about the assignment, the audience, or the writer's own goals; whereas with poor writers 70 percent of the new ideas flowed from the topic itself. "All of this suggests that setting up goals to affect a reader is not only a reasonable act, but a powerful strategy for generating new ideas and exploring…a topic."

Here we have, I think, a way of closing the gap between news/speech and knowledge/writing. Perhaps, in setting up the dichotomy between news and knowledge, Percy underestimated the wiliness of the skilled writer. Perhaps the body of information that he calls knowledge is roughly equivalent to what a writer would work with under a plan *To Say*—the substantive points to be made. But Flower and Hayes say the mark of a good writer is the resources devoted to the aspects of the problem other than the substantive points, especially the strategy *To Do*. Attention to these areas—and in particular, treating the audience as a vivid entity—is what distinguishes those who can turn the process of creating text into a "complex speech act." For such writers, conversational prose not only is possible, it is what they tend to produce.[a] Thus to move writing back toward speech and knowledge back toward news, a writer should be urged to treat the nonsubstantive aspects of the assignment with the importance they deserve. It usually will not be possible to retain all the density of argumentation that knowledge/writing can achieve, but a surprising percentage can be preserved, and what does get set out has a much better chance of actually being transferred.

a. This notion is buttressed by the examples of "good writing" included in my favorite how-to-write book, Jacques Barzun's *Simple and Direct*. The writers whom Barzun singled out range from Dorothy Sayers to Eric Hoffer to a man writing about how to use a saw. Nearly all of them, and Barzun himself for that matter, produced what I have been calling conversational prose.

	Analysis of rhetorical situation: Audience and Assignment		Analysis of goals			
		Audience	Self	Text	Meaning	Total
Novice	7	0	0	3	7	17
Expert	18	11	1	3	9	42
Number of times writer explicitly represented each aspect of the rhetorical problem in first 60 lines of protocol						

V. Creativity and the Conceptual Front End

One of the enduring concerns of DI analysts is the creativity issue. What role is there for creativity in a structured, basically hierarchical organization—an organization, moreover, that operates more or less according to craft-work standards? Doesn't such an organization run the risk of stunting creativity, making do with run-of-the-mill analysis, and perhaps missing important trends? On the other hand, some might argue that creativity is not even particularly relevant to what we do. The important goal is to meet the needs (stated and implicit) of our consumers in a timely and accurate way, and tons of creativity will not help if this goal is not met. An organization has both the ability and the obligation to impose norms, these people might argue; constraints of some sort are bound to turn up sooner or later, and they almost certainly will seem arbitrary when they do. So why not impose the constraints of the craft, which at least have the virtue of some consistency and continuity?

What role is there for creativity in a structured, basically hierarchical organization ?

This argument is clouded by a definitional problem which needs to be disposed of before we can address the issue constructively. Creativity usually is treated as a rare phenomenon, and so it is under the usual definition. But the whole cognitive process actually has a creative component, and in this specific sense creativity is all around us. I believe many of the problems confronting an organization like the DI, whose raison d'etre is the intellectual activity of the people who comprise it, flow from the conflict between these two sorts of creativity.

Herbert Simon provides a useful list of the criteria by which the creative aspect of a piece of work is judged:

- The work has novelty and value (either for the originator or for his culture).
- It is unconventional in the sense that it requires modification or rejection of previously accepted ideas.
- It requires high motivation and persistence, taking place either over a considerable span of time (continuously or intermittently) or at high intensity.
- The problem as initially posed was vague and ill-defined, so that part of the task was to formulate the problem itself.[a]

Simon notes that not all the criteria need be satisfied before a work is considered creative. I would go further and assert that for the individual producing the work, one criterion suffices by itself: that the work have "novelty and value…for the originator." Furthermore, the nature of the cognitive process is such that almost everything produced will meet this criterion. I noted early in this essay that a child's approach to the learning of a language has a creative as well as a satisficing element. A child discovers how language works by constructing original sentences, sentences that did not exist until he formed them. I suspect that pleasure at having produced something new is a powerful force for further linguistic exploration and that an overlearned (and thus unconscious) sense of satisfaction accounts for part of the conversational dynamic in adults.

The creative component in this narrow, individualistic sense is if anything even more apparent with written work. With speech, the words are ephemeral and part of a social process. The individual producing them cannot get too closely identified with them; they are tossed into the conversational stream and soon are lost to consciousness, leaving nothing behind but an assortment of conceptual chunks in the memories of those participating

a. Simon, *Models of Thought*, 139.

in the exchange. (People do, of course, identify themselves closely with the chunks.) By contrast, a person producing a written sentence is bringing something discrete and durable into existence, and I would suppose that the sense of having created something is all the stronger for that reason. The private nature of the writing process reinforces this sense. Moreover, the imbalance in emotional investment between producer and consumer—the one closely involved with the specific words, the other much less so—is likely to be more apparent with writing.

The writer must circulate his text to others; this is part of his unspoken contract with the rest of the world. The criteria at this point, however, are the other items on Simon's list, which are all essentially social rather than individual, and society discerns creativity less often than the individual does in himself. An organization, moreover, is necessarily concerned with standards of some sort, and it has a right to require a degree of conformity from the journeyman.

Acceptance of such norms does not always hobble creativity. Until the last couple of centuries much of the great art was produced by people whose outlook was that of craftsmen. Consider the following comment by Jerome Bruner:

> *One cannot help but compare the autobiographic fragment left by Ghiberti, discussing the long period during which he worked on the famous doors of the Baptistery at Florence, with the personal writing, say, of a modern sculptor like Henry Moore. Ghiberti talks of the material that was "needed" to do the designs that were "required." It is as if it were all "out there." Moore is concerned with the creating of illusions and symbols, and self-awareness for him is as important as a stone chisel.*[a]

Yet it does seem to me that creativity is important for an organization like the DI, and that such an organization constantly runs the risk of inhibiting the creative component in the work of its people. Few, I suspect, would dispute the proposition that satisfying consumer needs is aided by a certain degree of creativity, and to me it is equally obvious that some sort of creativity is essential if the directorate is to satisfy the predictive aspect of its mission as well as possible. I would also suppose that work deemed creative under Simon's broader, socially determined criteria must have creativity in the narrow sense as a precondition. It is here that the risks arise for an organization like the DI. The following examples cited by Morton Hunt support this argument.

> *In one of Torrance's many studies of creativity in school children, children were given pencils, crayons, and simple collage materials and told to make a picture that no one else would be likely to come up with. A variety of kinds of comment and appraisal were given to different groups of the children, and some got no evaluation at all. The upshot: those who worked without evaluation turned out pictures that were more creative than those produced by children receiving the most constructive commentary. In a study by another researcher, a group of students were told they would earn a reward for thinking up the largest number of plot titles and stories; their output was less imaginative and original than that of another group who expected no reward. Merely, knowing that one's work will be critically appraised by experts after it is finished has a negative influence. Teresa Amabile, in her collage studies, told one group of college women that their efforts would be judged by artists, while another group was told nothing; the latter group did significantly more creative work.*[b]

One can easily criticize research such as this. For example, how is it possible to judge something as subjective as creativity? Might not the researchers have gone into their studies with biases that skewed the results? Perhaps a more telling point is that the subjects of the experiments seem not to have had much skill or experience in the activities they were engaged in, and thus may have been particularly sensitive to the notion of being judged. One might expect a more complex situation, for

a. Bruner, *On Knowing*, 54.

b. Morton Hunt, *The Universe Within*, 313.

instance, if an experienced artist was faced with the possibility of being judged by other artists. But even taking such objections into account, the notion of creativity being inhibited by the mere prospect of outside comment—even positive comment—is thought-provoking. Even a skilled artist might be inhibited if he was required to keep in the front of his mind the evaluation to which his work was to be submitted. Yet this is a requirement which a structured organization can hardly avoid imposing.

Or consider the comment by Jacob Bronowski in his Silliman lectures at Yale in 1967:

> *The society of scientists, the community of scientists, has this advantage, that from the moment we enter it, we all know that fifty years from now, most of the things we learned here will turn out not to have been quite right. And yet that will have been achieved without enormous personal dramas. It will be achieved by giving due honor to the people who take the steps, the steps that turn out to be wrong as well as the steps that turn out to be right.*[a]

Again one can quibble: surely it is only the "steps that turn out to be right" which win Nobel prizes. But the essence of Bronowski's argument is hard to dispute. Science does reserve a place of honor for those who explore blind alleys, not least because discovery is as likely to proceed from an earlier error or ambiguity as from an earlier truth. The place of error in a structured organization, on the other hand, is much less certain, particularly if accountability is one of the driving forces in that organization. Even with the best will in the world such an organization is likely to put a premium on being right. As a result tentative ideas may have a harder time surviving, and there may be a tendency to equate "being right" with "not being wrong." If so, caution and the school solution will have an easier time of it than they might otherwise have.

a. Jacob Bronowski, *The Origins of Knowledge and Imagination* (New Haven: Yale University Press, 1978), 133.

And yet the Directorate of Intelligence cannot devote many of its resources to nurturing creativity, at least under any very expansive definition of the term. Like any craft organization, the DI has jobs to do, and worrying about creativity would often get in the way. Moreover, much of the activity we report and analyze is actually pretty ordinary or closely tied to a narrow set of events, and with work of such an ephemeral nature the scope for creativity is limited. Finally, there is no guarantee that you will get more creativity if you do nurture it. I know of no approach that has proven more capable than others of producing results which are simultaneously creative, valid, relevant, and efficient.

Yet, the DI cannot devote many resources to nurturing creativity... it has jobs to do and worrying about creativity would often get in the way.

The concepts discussed in this essay do, however, offer some hints about reducing the tension between structure and creativity—reducing rather than eliminating, since the sources of tension will not go away and we are certain to wind up satisficing. The key is the importance of the work we do right at the outset of the process. Simon notes at one point, "Much of the skilled processing in chess occurs at the perceptual front end." This proposition holds for all cognitive activity, although in the DI's case it may be more accurate to talk about a conceptual rather than a perceptual front end. Being clear what is going on at the beginning takes on overwhelming importance in light of cognitive scientists' findings; moreover, there is a built-in potential for conflict between what happens at the conceptual front end and what happens during a necessarily serial review process.

The importance, as well as the difficulty, of defining what is happening at the start is put into clearer relief by an obvious point made by Flower and Hayes: "People only solve the problems they give themselves." I cannot give you a problem to solve; I can try to interest you in a problem; I can talk it through it with you; if I am your boss, I can order you to take it on. But the problem you solve still will be the one you pose to yourself, not the one I have given you. The two will rarely be congruent, and if we are not clear with each other they may diverge

drastically. Each of us will have sharply narrowed our concept of the problem by the time we begin to talk about it, and neither my concept nor yours will be confined to the substance of the issue. We both will have a complex set of assumptions as well as an assortment of goals, usually unspoken, that we hope to achieve. If I am your boss one of my goals might be, "Try once more to get some worthwhile prose out of this analyst." You, the subordinate, might have "Get this guy off my back" as one of yours. Both goals will affect the product—your goals more than mine, in fact, since as the one in charge of the keyboard you have the biggest role in deciding how the problem will actually be solved.[a]

The problem you give yourself to solve is roughly equivalent to your strategy *To Do*—the rhetorical challenge in all its complexity, as it is posed by the person meeting it. This is easily the most important part of the "conceptual front end" to articulate, particularly if the topic is difficult or controversial or if it is breaking new analytic ground. I suspect it is the part that is least well articulated for much of the DI's work. Most of the time we focus on the areas of *To Say* and *To Compose*—the points we are going to make and the way we are going to express them. But problems in these areas are often easy to fix. It is the unspoken divergences at the level of plans *To Do*, I believe, that cause the real headaches. This is particularly true if such divergences do not come to light until a paper makes its way up through the hierarchy.

It is terribly hard to articulate one's strategies at this level. In the ivory-tower setting of this paper I can make the obvious point that everyone benefits when a goal like "Show those turkeys downtown how stupid they are" is brought into the open, or when a reviewer-to-be makes explicit a line of attack that looks promising. In a real-life situation, however, it is in the nature of assumptions that they do not even get noticed, much less articulated. And articulated in the context of the specific situation: if an assumption is not so articulated, you can never be sure it is common property, given the idiosyncratic way each of us chunks the information at our disposal. The post-facto "any-fool-should-have-known" argument is always an unsatisfactory substitute.

A sure way not to illumine a strategy *To Do* is to develop nothing but an outline, since outlines are necessarily concerned mainly with plans *To Say*. Concept papers will shed more light, but in my experience they rarely are fully satisfactory. This is at least partly because strategies *To Do* typically get articulated bit by bit (once again we meet the proposition that learning and insight are achieved heuristically and incrementally). Thus the actual process of finding out what has happened at the beginning of the conceptual process takes time. It involves a series of exchanges, not just at the formal inception of a project but even before it takes shape and also as it progresses.

Not all analysts find such exchanges congenial, managers at all levels begrudge the time, and divergences among various strategies *To Do* are not always resolved amicably. And indeed not all projects are worth spending too much time on. But to the degree that all concerned—higher level reviewers as well as those actually involved in the writing—can work early and often at narrowing the gaps among various conceptions of the rhetorical problem, the chances of a bumpy review process will diminish. Perhaps more important, the chances of preserving whatever creativity there is will be enhanced. And finally, hammering out differences at the level of strategies *To Do* might make a virtue of necessity: it might give a more collegial cast to a process whose hierarchical aspects are built-in and inescapable.[b]

a. Many analysts may cavil at the last statement, arguing that the review process has left them no longer in charge of their own prose. Perhaps analysts do have less control than in earlier eras, but I would argue that because they are the ones constructing the prose, for better or for worse they remain by far the most influential factors in what gets produced.

b. Looking at the problem in this way exposes an anomaly in a related area. As we have seen, the value of experience—experience extending over a decade or more—is well documented in the cognitive-science literature. Such experience generally makes itself felt at higher levels of problem solving; a first-class composer or a chess grandmaster stands out because of his skill at a level analogous to Flower and Hayes's strategy *To Do*. In the DI the people in upper levels of management have a high concentration of experience of this sort, yet the serial nature of the review process and the other demands of their job make it hard for them to bring it to bear at the point where

(Editor's note: At the time of this monograph's original appearance there were developments on the horizon that promised profound effects on the way DI analysts did business in just these areas. Project SAFE and the concurrent development of AIM appeared with recurrent troubles that tended to buttress the negative mindsets of many in the directorate at the time. Their potential attractiveness became apparent before long. The attractiveness in this context arose not from the information-retrieval aspect of SAFE, but from the interactive capabilities of the partner development, AIM, which was designed to permit frequent written exchanges between analysts–December 2009.)

If the history of such systems is any guide, DI analysts are likely to find interaction of this sort a congenial way to work. If they perceive the initial capability to be inferior to what is available elsewhere, they are likely to press for greater speed, comprehensiveness, and flexibility.

AIM's interactive capacity will be a boon in many ways, but it will also pose new managerial challenges:

- It will encourage collegiality among analysts concerned with various aspects of the same problem—an important advantage in the expanded directorate. It will not magically eliminate parochialism and dog-in-the-manger attitudes, but to the extent it is used, it will help analysts establish communication and get around competitive barriers.

- Exchanges via AIM will be informal and basically conversational, and there is every reason to expect some of the conversational flavor to carry over into more formal products. Thus AIM seems likely to foster the sort of prose called for earlier in this essay. If it does, of course, it will also raise the sort of managerial questions discussed there.

- AIM seems well suited to the incremental articulation of strategies *To Do*. Those involved in the exchanges are likely to develop clearer notions—and a higher degree of consensus—about what their purposes are.

There never will be dependable correlation between the intensity of the interaction and the quality of the product.

- But those who do not participate will have a harder time catching up. This means, among other things, that potential reviewers may find it even more difficult to make contact with the problem-defining process unless they keep current as it progresses—unless they participate in the written as well as the spoken interplay. The potential for heavier demands on managers' time is obvious.

- At the same time, collegiality could work at cross purposes with hierarchy. What would it do for a division or branch chief's authority, for example, if the office director used AIM to get deeply involved in helping an analyst define a rhetorical problem?

- Nor will the system be uniformly beneficial on the substantive side. Writing still will be essentially a private process, and some analysts will not function at their best if they have to work in a sort of electronic marketplace of ideas. Others may find the exchanges so much fun that they forgo analytic digging. There never will be dependable correlation between the intensity of the interaction and the quality of the product.

strategies *To Do* are evolving.

VI. What Next?

Out of this discussion grow numerous questions about the way the directorate goes about its business. They include the following subject areas.

1. Recruitment.

Is there any way in pre-employment interviews to focus more sharply on the way a prospective employee deals with strategies *To Do* (and perhaps *To Compose*)? More pointedly, in hiring decisions should more weight be given to these attributes and less to skills of the *To-Say* variety? Should we look harder for writers and reporters and less hard for scholars? Should we count more on internal training and put less reliance on what an individual has learned before coming aboard? Should there be sharper distinctions in approach between disciplines—would it be reasonable, just for example, to require advanced degrees for economists but to emphasize BAs among political analysts? There never will be absolute answers to questions like these, but the ideas laid out in this essay make affirmative answers plausible in many cases. It also would be worthwhile seeing if there are any tests that get at skills of the *To-Do* variety.

2. Training.

If it is correct that around 10 years are needed to acquire the conceptual network necessary for first-class work, what are the implications for the way the directorate goes about its training effort? Presumably an analyst is well into the notional 10 years on his or her arrival, but it still might be prudent at that point to anticipate another 5 years of development. If so, it seems to me, more careful attention needs to be given to how the analyst learns the trade, and training should figure far more heavily in the DI's thinking than it does now. I would suggest that if what is involved is, in fact, craftwork, nearly all the training should be on the job. It even might make sense to make training one of the specific functions discussed on a branch chief's performance appraisal report (PAR). The question would then shift to how branch chiefs should be trained. (An exercise of this sort might also produce a broader examination of the branch chief's functions—an examination I think the directorate would find illuminating.)

3. Analytic Writing.

The suggestions in this essay about conversational prose mesh with some of the trends already underway in the DI. If the best route to that sort of writing is to build a vivid image of one's audience, then frequent contact with the audience is likely to prove a useful tool for sharpening the writer's effectiveness. Moreover, the notion of bringing the audience into focus should help writer and reviewers establish common ground to work out the nonsubstantive aspects of a paper.[a] Beyond that, I would suggest that the vocabulary of cognitive science (and the concepts behind it) will be useful to those involved in teaching analytic writing, both on the job and elsewhere.

4. Organization.

I have suggested that there is an unavoidable conflict between the way an organization operates and the way the individuals in the organization do their cognitive work. Estimating the costs imposed on the organization by this conflict is impossible, since to do so one would have to guess what might have been produced but wasn't. It seems safe to say, however, that although the costs probably are lower than analysts believe, they probably are higher than many managers would admit. If so, some effort to ameliorate the conflict might prove worthwhile. Four lines of approach come to mind.

a. To an analyst, of course, the audience includes the chain of review; this may actually be the most important audience of all from his or her perspective. In addition, it should be obvious that an analyst will get a different sort of audience-image from working-level colleagues than from exposure to their bosses, and that secondhand information about the interests of the latter will have a tough time competing with the first-person experience. This is one of many conceptual gaps it will take repeated effort to bridge.

- *First, divorcing substance from hierarchy as often as possible.* This means exchanges between managers and analysts at times when a paper is neither under review nor in prospect—at conferences, for example, or simply as part of everyday chitchat. The greater the hierarchical gap, the harder such exchanges are to arrange, but the more valuable they might prove to be. To the extent that nonhierarchical channels for feedback can be developed, I believe the chances of operating at cross purposes when something is on the line will be reduced.

- *Second, hierarchy-jumping in contacts with consumers.* The desk analyst, in my opinion, would benefit enormously from learning firsthand what is on the minds of high-ranking officials.

- *Third, enfolding AIM's interactive function into the culture of the directorate.* Interactive systems are basically democratic, and I believe that properly used, they can reduce the height of organizational barriers.

- *Fourth, giving more articulation to assumptions at the level of strategies* To Do. One way this might be done is to modify the format of concept papers. Putting such papers in the first person, and replacing impersonal constructions ("This paper will examine…") with straightforward questions ("What will happen if…?") would help to make the rhetorical scheme more visible. AIM and extrahierarchical exchanges will have a similar effect.

- If a videotape were to be produced in which an analyst discussed the findings of a freshly produced paper, those findings would almost certainly make it across the gap between knowledge and news. Many in the DI's potential audience would probably find an extemporaneous discussion much more vivid than words on paper. The list of objections to the idea, of course, is formidable—the loss of precision as the analyst speaks extemporaneously, the time involved in producing even an informal discussion, the problem of defining the audience, the dilution of the sense that the paper is a product of the directorate as an institutional entity. But the benefits, if the tape was done right, might be equally impressive.

- Television might offer a better way of laying out alternative hypotheses. I have trouble believing that the present method, in which heated disagreements are set forth in determinedly flat prose, captures enough of the flavor to be much help. Taping a live discussion among experts might do a better job.

- In fast-breaking situations of prime importance, it might be useful to supplement other forms of current intelligence with televised analytic commentary. These days, current intelligence at its best almost exactly fulfills Walker Percy's criteria for news: it produces information bearing on the reader's predicament and it is carried by a newsbearer. Videotape would let a knowledgeable analyst be called into service as a specialized newsbearer on matters of great moment.

5. Presentational Methods.

Conversational prose is one way to bridge the gap between speech and writing, but are there others? Can more extensive use be made, for example, of television, whose effectiveness as an intelligence medium has already been proven in a limited way? I am thinking of something less formal, more ephemeral, and more personalized than what has been produced so far. Three possibilities spring to mind.

6. Further Exploration.

The DI might benefit from using cognitive-science techniques to analyze the production process. After reading an earlier draft of this essay, for example, Professor J.R. Hayes of Carnegie-Mellon University suggested a "cognitive task analysis of what analysts do. This information could aid the design of systems such as SAFE [and AIM]." Hayes has also suggested that we could do our own oral protocols of an analyst—or a reviewer—at work; he adds that

observing the reviewer might give particularly illuminating insights into the process.

Moreover, the notions in this essay exploit only a part of the expertise in cognitive science. For example, there is considerable disagreement in the field over the role of language in the cognitive process. Many would argue against the emphasis I have placed on the written word. They would say that such concentration significantly limits the directorate's analytic flexibility. Others might assert that I have understated the degree to which computers can supplement our mental processes. Exploration of either field (they are not mutually exclusive) might bring further benefits to the DI's analytic effort. At this point, however, we leave the area in which I can even pretend to competence.

Afterword

This list of suggestions points up once again the difficulty of the cognitive activities in which the DI is engaged. The difficulties arise because, as this essay has tried to show, the directorate must mediate a series of irreconcilable demands:

- Between the individual, private nature of the analytic effort and the social and hierarchical constraints imposed by bureaucratic imperatives.
- Between the cognitive patterns that are necessary to develop complex ideas (patterns that can only operate through writing) and the patterns our speech- and news-oriented customers are comfortable with.
- Between the early point at which critical analytic decisions are made and the serial nature of the review process.
- Between the need to search for new insights—to explore the murkier reaches of a problem space—and the need to avoid mistakes.

These conflicts have always been present, and we probably have always been aware of them, more or less. But as the DI grows and works out the implications of the trend toward centralization, as it spreads its analytic net more broadly and uses a finer mesh, they are likely to become more acute.

It would be easy to find a catalogue of conflicts like this depressing—to feel a bit like the centipede after its mind was set churning by the frog. But unlike centipedes (even sentient ones), humans can also treat such conflicts as a challenge. Indeed it seems to be part of our nature to see a situation as a problem to be solved. Morton Hunt notes:

> *We* perceive *situations as problems, and therefore undertake to solve them. An ape, coming to a broad river, would see it merely as an end to further travel in that direction; a human being might see it as a body of water to be crossed, and thereupon invent a raft. Innate neural impulses and early learning provide each species of animal with the specific procedures it needs to obtain food, avoid enemies, mate, care for its young, and so on; human beings, too, acquire procedures for dealing with these basic problems, but they also solve countless others that did not exist until their own minds saw them as problems. Art and arithmetic, music and money, detergents and democracy are all solutions to problems created not by Nature but by the human mind.*
>
> *Problem solving is virtually species-specific, but what is absolutely species-specific and ultimately human is* problem generating. *The problem is in the eye of the beholder, and we are beholders.*[a]

We are, in fact, better at generating problems than at solving them. Rarely can we say unequivocally that we have solved a problem, particularly if it is a hard one. Rather we keep plugging away

a. Hunt, *The Universe Within*, 240.

at it heuristically. Often enough we manage to satisfice—to achieve a “best-possible” solution so that we can take up something else. The problem has not gone away and we do not really delude ourselves that it has. But being realists (i.e., heuristic individuals to the core), we accept the results and live with them—recognizing that sometime we may find ourselves returning to the problem once more. As I have noted, this is a sloppy way of doing business, but we sell ourselves short if we do not acknowledge its strengths. It deals as well as anything yet developed with the fact, to use Jerome Bruner’s words, that our “ability to deal with knowledge is hugely exceeded by the potential knowledge contained in man’s environment.”

The gross imbalance between what humans can know and what is available to be known is nowhere more apparent than in the Directorate of Intelligence. Indeed this is the central dilemma the DI faces. We have always coped with the dilemma in a typically heuristic, satisficing way, and there is no reason to suppose this approach will change. My own impression, however, is that the directorate has never articulated the nature of the dilemma very clearly—a fine example of how hard it is to talk about the “conceptual front end.” A clearer notion of what the pressures are, and of what there is in our own makeup that makes them so powerful, should enable us to make better use of the power inherent in the heuristic approach. We never will get away from the need to satisfice—in other words, we always will be able to look at a given solution to a problem and see ways to make it better—but with greater understanding of what we are about, we may be able to attain a level of satisficing that we are more content with.

A Tradecraft Primer:
Structured Analytic Techniques
for Improving Intelligence Analysis

Prepared by the US Government

March 2009

This primer highlights structured analytic techniques—some widely used in the private sector and academia, some unique to the intelligence profession. It is not a comprehensive overview of how intelligence officers conduct analysis. Rather, the primer highlights how structured analytic techniques can help one challenge judgments, identify mental mindsets, stimulate creativity, and manage uncertainty. In short, incorporating regular use of techniques such as these can enable one to structure thinking for wrestling with difficult questions.

TABLE OF CONTENTS

Introduction 1

How To Use These Techniques 5

Diagnostic Techniques 7

Strategies for Using Structured Analytic Techniques 38

Selective Bibliography 40

THE "MIND-SET" CHALLENGE

Using the analytic techniques contained in this primer will assist analysts in dealing with the perennial problems of intelligence: the complexity of international developments, incomplete and ambiguous information, and the inherent limitations of the human mind. Understanding the intentions and capabilities of adversaries and other foreign actors is challenging, especially when either or both are concealed. Moreover, transnational threats today pose even greater complexity, in that they involve multiple actors—including nonstate entities—that can adapt and transform themselves faster than those who seek to monitor and contain them. Finally, globalization has increased the diversity of outcomes when complex, interactive systems such as financial flows, regional economies or the international system as a whole are in flux.[2]

The first hurdle for analysts is identifying the relevant and diagnostic information from the increasing volume of ambiguous and contradictory data that is acquired through open source and clandestine means. Analysts must also pierce the shroud of secrecy—and sometimes deception—that state and nonstate actors use to mislead. A systematic approach that considers a range of alternative explanations and outcomes offers one way to ensure that analysts do not dismiss potentially relevant hypotheses and supporting information resulting in missed opportunities to warn.

Cognitive and perceptual biases in human perception and judgment are another important reason for analysts to consider alternatives. As Richards Heuer and others have argued, all individuals assimilate and evaluate information through the medium of "mental models" (sometimes also called "frames" or "mind-sets"). These are experience-based constructs of assumptions and expectations both about the world in general and more specific domains. These constructs strongly influence what information analysts will accept—that is, data that are in accordance with analysts' unconscious mental models are more likely to be perceived and remembered than information that is at odds with them.

Mental models are critical to allowing individuals to process what otherwise would be an incomprehensible volume of information. Yet, they can cause analysts to overlook, reject, or forget important incoming or missing information that is not in accord with their assumptions and expectations. Seasoned analysts may be more susceptible to these mind-set problems as a result of their expertise and past success in using time-tested mental models. The key risks of mind-sets are that: analysts perceive what they expect to perceive; once formed, they are resistant to change; new information is assimilated, sometimes erroneously, into existing mental models; and conflicting information is often dismissed or ignored.

> *"Intelligence analysts should be self-conscious about their reasoning processes. They should think about how they make judgments and reach conclusions, not just about the judgments and conclusions themselves."*
>
> —Richards Heuer, *The Psychology of Intelligence Analysis*[1]

[1] Richards J. Heuer, Jr., *The Psychology of Intelligence Analysis* (Washington: Center for the Study of Intelligence, 1999).

[2] These observations were drawn from a lengthier treatment of cognitive bias found in the Sherman Kent Center's Occasional Paper, *Making Sense of Transnational Threats*, Vol. 3, No. 1, October 2004.

Common Perceptual and Cognitive Biases

Perceptual Biases

Expectations. We tend to perceive what we expect to perceive. More (unambiguous) information is needed to recognize an unexpected phenomenon.

Resistance. Perceptions resist change even in the face of new evidence.

Ambiguities. Initial exposure to ambiguous or blurred stimuli interferes with accurate perception, even after more and better information becomes available.

Biases in Evaluating Evidence

Consistency. Conclusions drawn from a small body of consistent data engender more confidence than ones drawn from a larger body of less consistent data.

Missing Information. It is difficult to judge well the potential impact of missing evidence, even if the information gap is known.

Discredited Evidence. Even though evidence supporting a perception may be proved wrong, the perception may not quickly change.

Biases in Estimating Probabilities

Availability. Probability estimates are influenced by how easily one can imagine an event or recall similar instances.

Anchoring. Probability estimates are adjusted only incrementally in response to new information or further analysis.

Overconfidence. In translating feelings of certainty into a probability estimate, people are often overconfident, especially if they have considerable expertise.

Biases in Perceiving Causality

Rationality. Events are seen as part of an orderly, causal pattern. Randomness, accident and error tend to be rejected as explanations for observed events. For example, the extent to which other people or countries pursue a coherent, rational, goal-maximizing policy is overestimated.

Attribution. Behavior of others is attributed to some fixed nature of the person or country, while our own behavior is attributed to the situation in which we find ourselves.

Intelligence analysts must actively review the accuracy of their mind-sets by applying structured analytic techniques that will make those mental models more explicit and expose their key assumptions. The techniques found in this primer are designed to assist in this regard by:

- Instilling more structure into the intelligence analysis.
- Making analytic arguments more transparent by articulating them and challenging key assumptions.
- Stimulating more creative, "out-of-the-box" thinking and examining alternative outcomes, even those with low probability, to see if available data might support these outcomes.
- Identifying indicators of change (or signposts) that can reduce the chances of surprise.

Incorporating findings derived from these techniques into our intelligence products also serves the policymaker by:

- Highlighting potential changes that would alter key assessments or predictions.
- Identifying key assumptions, uncertainties, intelligence gaps and disagreements that might illuminate risks and costs associated with policy choices.
- Exploring alternative outcomes for which policy actions might be necessary.

Strategic Assumptions That Were Not Challenged

1941 World War II

Japan would avoid all-out war because it recognized US military superiority.

Given that US superiority would only increase, Japan might view a first strike as the only way to knock America out of the war.

1950s Korean War

China would not cross the Yalu River in support of the North Korean government.

Red China could make good on its threats to counter "US aggression" against the North.

1962 Cuban Missile Crisis

The Soviet Union would not introduce offensive nuclear weapons into Cuba.

The Kremlin could miscalculate and believe it could create a fait accompli that a young US President would not be prepared to reverse.

1973 Yom Kippur War

Arabs knew they could not win because they had failed to cooperate in the past and still lacked sufficient air defenses to counter Israeli airpower.

A surprise Arab attack, even if repelled, could wound Israel psychologically and prompt international calls for cease-fires and diplomatic negotiations.

1989 German Unification

East Germany could not unify with the West Germany against the wishes of the Soviet Union.

The Soviet Union—under Gorbachev—might not be prepared to intervene militarily in Eastern Europe as it had in the past.

1998 Indian Nuclear Test

Conducting a nuclear test risked international condemnation and US sanctions and would threaten a newly elected coalition government.

A successful and surprise nuclear test could boost Indian nationalist pride and solidify public support for a shaky coalition government.

2003 Iraq's WMD Programs

Saddam failed to cooperate with UN inspectors because he was continuing to develop weapons of mass destruction.

If Iraqi authorities had destroyed their WMD stocks and abandoned their programs, they might refuse to fully acknowledge this to the UN to maintain Iraq's regional status, deterrence, and internal regime stability.

HOW TO USE THESE TECHNIQUES

The analytic techniques in this primer are designed to help individual analysts, as well as teams, explore and challenge their analytical arguments and mind-sets. Some techniques are fairly simple to understand and employ—such as Brainstorming and Devil's Advocacy. Others are more complex and demand a greater degree of analytical sophistication, resource commitment, and time. All the techniques are included because they have helped other analysts avoid rigid ways of thinking or assisted them in exploring new outcomes or implications of an intelligence problem.

The techniques are grouped by their purpose: **diagnostic** techniques are primarily aimed at making analytic arguments, assumptions, or intelligence gaps more transparent; **contrarian** techniques explicitly challenge current thinking; and **imaginative thinking** techniques aim at developing new insights, different perspectives and/or develop alternative outcomes. In fact, many of the techniques will do some combination of these functions. However, analysts will want to select the tool that best accomplishes the specific task they set out for themselves. Although application of these techniques alone is no guarantee of analytic precision or accuracy of judgments, it does improve the sophistication and credibility of intelligence assessments as well as their usefulness to policymakers. As Richards Heuer notes in his own work on cognitive bias, "analysis can be improved."[3]

[3] Heuer, *Psychology of Intelligence Analysis*, p. 184.

KEY ASSUMPTIONS CHECK

List and review the key working assumptions on which fundamental judgments rest.

WHEN TO USE

A Key Assumptions Check is most useful at the beginning of an analytic project. An individual analyst or a team can spend an hour or two articulating and reviewing the key assumptions. Rechecking assumptions also can be valuable at any time prior to finalizing judgments, to insure that the assessment does not rest on flawed premises. Identifying hidden assumptions can be one of the most difficult challenges an analyst faces, as they are ideas held—often unconsciously—to be true and, therefore, are seldom examined and almost never challenged.

A key assumption is any hypothesis that analysts have accepted to be true and which forms the basis of the assessment. For example, military analysis may focus exclusively on analyzing key technical and military variables (sometimes called factors) of a military force and "assume" that these forces will be operated in a particular environment (desert, open plains, arctic conditions, etc.). Postulating other conditions or assumptions, however, could dramatically impact the assessment. Historically, US analysis of Soviet-Warsaw Pact operations against NATO had to "assume" a level of non-Soviet Warsaw Pact reliability (e.g., would these forces actually fight?). In this case, there was high uncertainty and depending on what level of reliability one assumed, the analyst could arrive at very different conclusions about a potential Soviet offensive operation. Or when economists assess the prospects for foreign economic reforms, they may consciously, or not, assume a degree of political stability in those countries or the region that may or may not exist in the future. Likewise, political analysts reviewing a developing country's domestic stability might unconsciously assume stable oil prices, when this key determinant of economic performance and underlying social peace might fluctuate. All of these examples highlight the fact that analysts often rely on stated and unstated assumptions to conduct their analysis. The goal is not to undermine or abandon key assumptions; rather, it is to make them explicit and identify what information or developments would demand rethinking them.

VALUE ADDED

Explicitly identifying working assumptions during an analytic project helps:

- Explain the logic of the analytic argument and expose faulty logic.
- Understand the key factors that shape an issue.
- Stimulate thinking about an issue.
- Uncover hidden relationships and links between key factors.
- Identify developments that would cause you to abandon an assumption.
- Prepare analysts for changed circumstances that could surprise them.

Key Assumptions Check: The 2002 DC Sniper Case

The outbreak of sniper shootings in the Washington, DC area in the fall of 2002 provides a good example of how this technique could have been applied. After the initial flurry of shootings, the operating assumption that quickly emerged was that the shootings were the work of a single, white male who had some military training and was driving a white van. If law enforcement officials had conducted a Key Assumptions Check, they could have broken this statement into its key components and assessed the validity of each statement as follows:

Key Assumption	Assessment
The sniper is a male.	Highly likely (but not certain) given past precedent with serial killers. We are taking little risk by not looking for a female.
The sniper is acting alone.	Highly likely (but not certain) given past precedents.
The sniper is white.	Likely, but not as certain, given past precedents. We would be taking some risk if we rule out nonwhites as suspects.
The sniper has military training/experience.	Possible, but not sufficient reason to exclude from consideration potential suspects who have not had any military training.
The sniper is driving a white van.	Possible because you have a credible eyewitness account but worthy of continuing scrutiny given the number of white vans in the area (more than 70,000 registered in the Maryland suburbs of Metropolitan Washington, DC) and that different kinds of vehicles are being described.

A Key Assumptions Check could have allowed law enforcement officials to:

- Avoid jumping to conclusions (the sniper is white, has military training, and is driving a white van) that did not hold up under closer scrutiny. By explicitly examining each assumption, officials could have avoided prematurely narrowing down the potential pool of suspects to a group that did not include the actual perpetrator. Similarly, they might have been more cautious about accepting that the sniper was driving a white van.
- Be receptive to new leads and citizen tips, such as eyewitness reports that the sniper fled the scene driving a specific model Chevrolet.
- More seriously consider evidence that subsequently became available, which contradicted a key assumption. If officials had stated explicitly that they were assuming the sniper was acting alone, they might have been sensitive to new information that contradicted that key assumption. Often this type of information gets “lost in the noise” if the analyst has not already thought about what key assumptions he or she is making.

THE METHOD

Checking for key assumptions requires analysts to consider how their analysis depends on the validity of certain premises, which they do not routinely question or believe to be in doubt. A four-step process will help analysts:

1. Review what the current analytic line on this issue appears to be; write it down for all to see.

2. Articulate all the premises, both stated and unstated in finished intelligence, which are accepted as true for this analytic line to be valid.

3. Challenge each assumption, asking why it "must" be true and whether it remains valid under all conditions.

4. Refine the list of key assumptions to contain only those that "must be true" to sustain your analytic line; consider under what conditions or in the face of what information these assumptions might not hold.

QUESTIONS TO ASK DURING THIS PROCESS INCLUDE:

- How much confidence exists that this assumption is correct?
- What explains the degree of confidence in the assumption?
- What circumstances or information might undermine this assumption?
- Is a key assumption more likely a key uncertainty or key factor?
- Could the assumption have been true in the past but less so now?
- If the assumption proves to be wrong, would it significantly alter the analytic line? How?
- Has this process identified new factors that need further analysis?

QUALITY OF INFORMATION CHECK

Evaluates completeness and soundness of available information sources.

WHEN TO USE

Weighing the validity of sources is a key feature of any critical thinking. Moreover, establishing how much confidence one puts in analytic judgments should ultimately rest on how accurate and reliable the information base is. Hence, checking the quality of information used in intelligence analysis is an ongoing, continuous process. Having multiple sources on an issue is not a substitute for having good information that has been thoroughly examined. Analysts should perform periodic checks of the information base for their analytic judgments. Otherwise, important analytic judgments can become anchored to weak information, and any "caveats" attached to those judgments in the past can be forgotten or ignored over time.

If a major analytic assessment is planned, analysts should individually or collectively review the quality of their information and refresh their understanding of the strengths and weaknesses of past reporting on which an analytic line rests. Without understanding the context and conditions under which critical information has been provided, it will be difficult for analysts to assess the information's validity and establish a confidence level in an intelligence assessment.

VALUE ADDED

A thorough review of information sources provides analysts—as well as policymakers—with an accurate assessment of "what we know" and "what we do not know." It is also an opportunity to confirm that sources have been cited accurately. In the case of HUMINT, this will require extensive review of the sources' background information and access as well as his or her motivation for providing the information. Similarly, reviewing technical sourcing can sometimes reveal inadvertent errors in processing, translation, or interpretation that otherwise might have gone unnoticed.

In addition, a quality of information check can be valuable to both collectors and policymakers:

- It can help to detect possible deception and denial strategies by an adversary.
- It can identify key intelligence gaps and new requirements for collectors.
- It can assist policymakers in understanding how much confidence analysts are placing on analytic judgments.

THE METHOD

An analyst or a team might begin a quality of information check by developing a database in which information is stored according to source type and date, with additional notations indicating strengths or weaknesses in those sources.[4] Ideally, analysts would have a retrieval and search capability on the database, so that periodic reviews are less labor intensive and result in a more complete review of all sources used in past analysis. For the information review to be fully effective, analysts will need as much background information on sources as is feasible. Knowing the circumstances in which reporting was obtained is often critical to understanding its validity. With the data in hand, analysts can then:

- Review systematically all sources for accuracy.
- Identify information sources that appear most critical or compelling.
- Check for sufficient and strong corroboration of critical reporting.
- Reexamine previously dismissed information in light of new facts or circumstances that cast it in a different light.
- Ensure that any recalled reporting is identified and properly flagged for other analysts; analysis based on recalled reporting should also be reviewed to determine if the reporting was essential to the judgments made.
- Consider whether ambiguous information has been interpreted and caveated properly.
- Indicate a level of confidence that analysts can place in sources, which are likely to figure in future analytic assessments.

[4] Analysis of Competing Hypotheses (ACH), discussed later in the primer, is a useful technique for exploring the possibility that deception could explain the absence of evidence.

Quality of Information Problem on Iraq

". . . Analysts community wide are unable to make fully informed judgments on the information they received, relying instead on nonspecific source lines to reach their assessments. Moreover, relevant operational data is nearly always withheld from analysts, putting them at a further analytical disadvantage . . ."

—*Senate Select Committee on Intelligence, Report on the US Intelligence Community's Prewar Intelligence Assessments on Iraq*

"Analytic errors included over-reliance on a single, ambiguous source, [and, in addition to collection shortfalls] failure of analysts to understand fully the limitations of technical collection . . ."

"The Intelligence Community relied too heavily on ambiguous imagery indicators . . ."

—*Commission on the Intelligence Capabilities of the United States Regarding Weapons of Mass Destruction.*

INDICATORS OR SIGNPOSTS OF CHANGE

Periodically review a list of observable events or trends to track events, monitor targets, spot emerging trends, and warn of unanticipated change.

WHEN TO USE

An analyst or team can create an indicators or signposts list of observable events that one would expect to see if a postulated situation is developing; e.g., economic reform, military modernization, political instability, or democratization. Constructing the list might require only a few hours or as much as several days to identify the critical variables associated with the targeted issue. The technique can be used whenever an analyst needs to track an event over time to monitor and evaluate changes. However, it can also be a very powerful aid in supporting other structured methods explained later in this primer. In those instances, analysts would be watching for mounting evidence to support a particular hypothesis, low-probability event, or scenario.

When there are sharply divided views on an issue, an indicators or signposts list can also "depersonalize" the argument by shifting analytic attention to a more objective set of criteria. Using an indicators list can clarify substantive disagreements, once all sides agree on the set of objective criteria used to measure the topic under study.

VALUE ADDED

By providing an objective baseline for tracking events or targets, indicators instill rigor into the analytic process and enhance the credibility of analytic judgments. An indicators list included in a finished product also allows the policymaker to track developments and builds a more concrete case for the analytic judgments. By laying out a list of critical variables, analysts also will be generating hypotheses regarding why they expect to see the presence of such factors. In so doing, analysts make the analytic line much more transparent and available for scrutiny by others.

THE METHOD

Whether used alone, or in combination with other structured analysis, the process is the same:

- Identify a set of competing hypotheses or scenarios.
- Create separate lists of potential activities, statements, or events expected for each hypothesis or scenario.
- Regularly review and update the indicators lists to see which are changing.
- Identify the most likely or most correct hypotheses or scenarios, based on the number of changed indicators that are observed.

Developing two lists of indicators for each hypothesis or scenario may prove useful to distinguish between indicators that a development is or is not emerging. This is particularly useful in a "What If?" Analysis, when it is important to make a case that a certain event is unlikely to happen.

Tracking the Potential for Political Instability in a Foreign Country

Topics	Indicators	1999				2000		
		I	*II*	*III*	*IV*	*I*	*II*	*III*
Government Capacity	Quality of leadership/organizational capabilities	●	●	●	■	●	●	●
	Responsiveness to popular demands	●	●	●	●	●	●	●
	Ability to deliver basic goods and services							
	Internal Security Capabilities							
	Effectiveness of civil/criminal justice systems							
Legitimacy of Regime	Breadth and depth of political participation	●	●	●	●	●	●	●
	Perceived level of corruption	●	●	●	●	●	●	●
	Human rights violations	●	●	●	●	●	●	●

	External support for government							
Opposition Activity	Ethnic/religious discontent	●	●	●	●	●	●	●
	Military discontent with civilian government	●	●	●	●	●	●	●
	Popular demonstrations/strikes/riots							
	Insurgent/separatist/terrorist group activity							
	External support for opposition							
	Threat of conflict with or in neighboring state							
Economic Factors	Weakness of domestic economy/unemployment/ inflation							
	Degree of income disparity							
	Capital flight							
	Decreased access to foreign funds							
	Reduced trade openness							
Environmental Issues	Extent of environmental degradation							
	Food/energy shortages							
	Ability to respond to natural disasters							

Presence of Trigger Mechanisms (▶ if present)							
Contested elections				▶			
Unpopular changes in food/energy prices			▶				
Sudden imposition of unpopular policies							
Coup plotting				▶			
Government mismanagement of natural disaster or national emergency							
Death of key figure							

■ Serious concern
● Substantial concern
● Moderate concern
● Low concern
● Negligible concern

Tracking the Potential for Political Instability in an Indicators Matrix. Analysts tracked the potential for regime change in 2000 and identified a list of indicators, to which they posed the question, "is this occurring or not? Analysts also went further and developed a list of "trigger mechanisms" that might bring about a political shift.

ANALYSIS OF COMPETING HYPOTHESES (ACH)

Identification of alternative explanations (hypotheses) and evaluation of all evidence that will disconfirm rather than confirm hypotheses.

WHEN TO USE

Analysis of Competing Hypotheses (ACH) has proved to be a highly effective technique when there is a large amount of data to absorb and evaluate. While a single analyst can use ACH, it is most effective with a small team that can challenge each other's evaluation of the evidence. Developing a matrix of hypotheses and loading already collected information into the matrix can be accomplished in a day or less. If the data must be reassembled, the initial phases of the ACH process may require additional time. Sometimes a facilitator or someone familiar with the technique can lead new analysts through this process for the first time.

ACH is particularly appropriate for controversial issues when analysts want to develop a clear record that shows what theories they have considered and how they arrived at their judgments. Developing the ACH matrix allows other analysts (or even policymakers) to review their analysis and identify areas of agreement and disagreement. Evidence can also be examined more systematically, and analysts have found that this makes the technique ideal for considering the possibility of deception and denial.

VALUE ADDED

ACH helps analysts overcome three common mistakes that can lead to inaccurate forecasts:

- Analysts often are susceptible to being unduly influenced by a first impression, based on incomplete data, an existing analytic line, or a single explanation that seems to fit well enough.
- Analysts seldom generate a full set of explanations or hypotheses at the outset of a project.
- Analysts often rely on evidence to support their preferred hypothesis, but which also is consistent with other explanations.

In essence, ACH helps analysts to avoid picking the first solution that seems satisfactory instead of going through all the possibilities to arrive at the very best solution.

THE METHOD

ACH demands that analysts explicitly identify all the reasonable alternative hypotheses, then array the evidence against each hypothesis—rather than evaluating the plausibility of each hypothesis one at a time. To create a level playing field, the process must:

- Ensure that all the information and argumentation is evaluated and given equal treatment or weight when considering each hypothesis.
- Prevent the analyst from premature closure on a particular explanation or hypothesis.
- Protect the analyst against innate tendencies to ignore or discount information that does not fit comfortably with the preferred explanation at the time.

To accomplish this, the process should follow these steps:

- Brainstorm among analysts with different perspectives to identify all possible hypotheses.
- List all significant evidence and arguments relevant to all the hypotheses.

- Prepare a matrix with hypotheses across the top and each piece of evidence on the side. Determine whether each piece of evidence is consistent, inconsistent, or not applicable to each hypothesis.[5]
- Refine the matrix and reconsider the hypotheses—in some cases, analysts will need to add new hypotheses and re-examine the information available.
- Focus on disproving hypotheses rather than proving one. Talley the pieces of evidence that are inconsistent and consistent with each hypothesis to see which explanations are the weakest and strongest.

[5] The "diagnostic value" of the evidence will emerge as analysts determine whether a piece of evidence is found to be consistent with only one hypothesis, or could support more than one or indeed all hypotheses. In the latter case, the evidence can be judged as unimportant to determining which hypothesis is more likely correct.

- Analyze how sensitive the ACH results are to a few critical items of evidence; should those pieces prove to be wrong, misleading, or subject to deception, how would it impact an explanation's validity?
- Ask what evidence is not being seen but would be expected for a given hypothesis to be true. Is denial and deception a possibility?
- Report all the conclusions, including the weaker hypotheses that should still be monitored as new information becomes available.
- Establish the relative likelihood for the hypotheses and report all the conclusions, including the weaker hypotheses that should still be monitored as new information becomes available.
- Identify and monitor indicators that would be both consistent and inconsistent with the full set of hypotheses. In the latter case, explore what could account for inconsistent data.

Terrorism in Tokyo From Aum Shinrikyo

		Weight	H: 1	H: 4	H: 2	H: 3
			Kooky Cult	Terrorist Group	Political Movement	Criminal Group
	Inconsistency Score ⇨		-1.0	-1.0	-2.0	-3.0
E3	Attacks on Journalists	MEDIUM	I	N	I	I
E2	Religious Affiliation	MEDIUM	C	I	I	I
E4	Established Party	MEDIUM	N	N	C	I
E1	Blind Leader Mastsumoto	MEDIUM	C	C	C	C

ACH Matrix of Terrorism in Tokyo. In March 1995, a largely unknown group attacked the Tokyo subways by using a highly lethal nerve agent known as sarin. ACH provides a mechanism to carefully examine all the evidence and possible explanations for understanding what type of group could have been responsible. In simplified form, the above matrix arrays each piece of evidence on the vertical axis and then evaluates each in terms of the item's consistency with four possible explanations for the terrorist attack in Tokyo (horizontal axis). Analysts rate a piece of evidence as consistent (C); inconsistent (I); or neutral (N). This process allows analysts to see that some evidence will be consistent with more than one hypothesis and be less valuable in disproving hypotheses.

DEVIL'S ADVOCACY

Challenging a single, strongly held view or consensus by building the best possible case for an alternative explanation.

WHEN TO USE

Devil's Advocacy is most effective when used to challenge an analytic consensus or a key assumption regarding a critically important intelligence question. On those issues that one cannot afford to get wrong, Devil's Advocacy can provide further confidence that the current analytic line will hold up to close scrutiny. An individual analyst can often assume the role of the Devil's Advocate if he or she has some doubts about a widely held view, or a manager might designate a courageous analyst to challenge the prevailing wisdom in order to reaffirm the group's confidence in those judgments. In some cases, the analyst or a team can review a key assumption of a critical judgment in the course of their work, or more likely, a separate analytic product can be generated that arrays all the arguments and data that support a contrary hypothesis. While this can involve some analytic time and effort, when a group of analysts have worked on an issue for a long period of time, it is probably wise to assume that a strong mind-set exists that deserves the closer scrutiny provided by Devil's Advocacy.

VALUE ADDED

Analysts have an obligation to policymakers to understand where their own analytic judgments might be weak and open to future challenge. Hence, the Devil's Advocacy process can highlight weaknesses in a current analytic judgment or alternatively help to reaffirm one's confidence in the prevailing judgments by:

- Explicitly challenging key assumptions to see if they will not hold up under some circumstances.
- Identifying any faulty logic or information that would undermine the key analytic judgments.
- Presenting alternative hypotheses that would explain the current body of information available to analysts.

Its primary value is to serve as a check on a dominant mind-set that can develop over time among even the best analysts who have followed an issue and formed strong consensus that there is only one way of looking at their issue. This mind-set phenomenon makes it more likely that contradictory evidence is dismissed or not given proper weight or consideration. An exercise aimed at highlighting such evidence and proposing another way of thinking about an issue can expose hidden assumptions and compel analysts to review their information with greater skepticism about their findings. The analyst could come away from the exercise more certain that: 1) the current analytic line was sound; 2) the argument is still the strongest, but that there are areas where further analysis is needed; or 3) some serious flaws in logic or supporting evidence suggest that the analytic line needs to be changed or at least caveated more heavily.

THE METHOD

To challenge the prevailing analytic line, the Devil's Advocate must:

- Outline the mainline judgment and key assumptions and characterize the evidence supporting that current analytic view.
- Select one or more assumptions—stated or not—that appear the most susceptible to challenge.
- Review the information used to determine whether any is of questionable validity, whether deception is possibly indicated, or whether major gaps exist.

- Highlight the evidence that could support an alternative hypothesis or contradicts the current thinking.

- Present to the group the findings that demonstrate there are flawed assumptions, poor quality evidence, or possible deception at work.

- Consider drafting a separate contrarian paper that lays out the arguments for a different analytic conclusion if the review uncovers major analytic flaws.

- Be sure that any products generated clearly lay out the conventional wisdom and are identified as an explicitly "Devil's Advocate" project; otherwise, the reader can become confused as to the current official view on the issue.

TEAM A/TEAM B

Use of separate analytic teams that contrast two (or more) strongly held views or competing hypotheses.

WHEN TO USE

A Team A/Team B approach is different from Devil's Advocacy, where the purpose is to challenge a single dominant mind-set. Instead, Team A/Team B recognizes that there may be competing and possibly equally strong mind-sets held on an issue that need to be clarified. Sometimes analysts confuse the two techniques by drafting a Team B exercise that is really a Devil's Advocacy exercise.

If there are at least two competing views within an analytic office or perhaps competing opinions within the policymaking community on a key issue, then Team A/Team B analysis can be the appropriate technique to use. Developing a full-blown Team A/Team B exercise requires a significant commitment of analytic time and resources, so it is worthwhile considering if the analytic issue merits this kind of attention.

A longstanding policy issue, a critical decision that has far-reaching implications, or a dispute within the analytic community that has obstructed effective cross-agency cooperation would be grounds for using Team A/Team B. If those circumstances exist, then analysts will need to review all of the data to develop alternative papers that can capture the essential differences between the two viewpoints.

VALUE ADDED

Managers have found that when there are office tensions among competing factions of analysts, a Team A/Team B approach can help opposing experts see the merit in the other group's perspective. The process of conducting such an exercise can reduce the friction and even narrow the differences. At a minimum, it allows those holding opposing views to feel that their views have been given equal attention.

For the policymaker, this technique helps to surface and explain important analytic differences within the expert community. Often senior officials can learn more by weighing well-argued conflicting views than from reading an assessment that masks substantive differences or drives analysis to the lowest common denominator. By making the key assumptions and information used for each argument more transparent, a policymaker can judge the merits of each case, pose questions back to the analysts, and reach an independent judgment on which argument is the strongest. Moreover, highlighting alternative views puts collectors on notice that they need to be searching for new information that can confirm or disconfirm a range of hypotheses.

If opposing positions are well established, it can be useful to place analysts on teams that will advocate positions they normally do not support; forcing analysts to argue "the other side" can often make them more aware of their own mind-set.

A Team A/Team B View: China's Military

A: *China's Hollow Military* by Bates Gill and Michael O'Hanlon	B: *China's Military: A Second Opinion* by James Lilley and Carl Ford
". . . We believe that the recent clamor over China's strategic ambitions is greatly overblown. Most of the Chinese aims that run counter to US interests are in fact not global or ideological but territorial in nature and confined primarily to the islands and waterways to China's south and southeast . . . An enormous gap separates China's military capabilities from its aspirations. The PRC's armed forces are not very good and not getting better very fast. Whatever China's concerns and intentions, its capacity to act upon them in ways inimical to US interests is severely limited, and will remain so for many years . . . The PRC's power projection capabilities, too, are constrained by huge weaknesses–especially in areas such as aerial refueling, electronic warfare, command and control and amphibious and air assault assets. China owns considerably less top-level equipment than medium powers like Japan and Britain; it owns even less than smaller powers such as Italy, South Korea or The Netherlands . . . The resources it devotes to acquiring modern weaponry are akin to those of countries spending $10-20 billion a year on defense . . ."	". . . We think they got it half right. China is no military superpower and will not acquire that status for some years to come. But measured in terms of its capacity to challenge key US allies in East Asia, China's capabilities have grown exponentially . . . By emphasizing direct comparisons between the defense capabilities of the United States and the PRC, the authors create an artificial and misleading construct . . . What the regime gives every indication of striving for is sufficient military clout to achieve its aims in Asia. In the short term, it wishes to intimidate Taiwan sufficiently to bring about unification on Beijing's terms . . . . . . Investments of the sort Beijing is making can mean only one thing: China is determined to improve the PLA's fighting capability. While most nations are reducing defense expenditures in the post–Cold War era, China is one of the few doing the opposite . . . Across the board, the PLA is engaged in a major spending effort to upgrade weapons and equipment and improve its operational capability. According to the Pentagon, these efforts have already enhanced China's ability to project military power . . ."

—Excerpted from journal articles found in The National Interest, Fall and Winter 2000/2001.

THE METHOD

Analysis Phase. A Team A/Team B exercise can be conducted on an important issue to:

- Identify the two (or more) competing hypotheses or points of view.
- Form teams or designate individuals to develop the best case that can be made for each hypothesis.
- Review all pertinent information that supports their respective positions.
- Identify missing information that would buttress their hypotheses.
- Structure each argument with an explicit presentation of key assumptions, key pieces of evidence, and careful articulation of the logic behind the argument.

Debate Phase. An oral presentation of the alternative arguments and rebuttals in parallel fashion can then be organized for the benefit of other analysts:

- Set aside time for an oral presentation of the alternative team findings; this can an informal brainstorming session or a more formal "debate."
- Have an independent "jury of peers" listen to the oral presentation and be prepared to question the teams regarding their assumptions, evidence, or logic.
- Allow each team to present their case, challenge the other team's arguments, and rebut the opponent's critique of its case.
- Let the jury consider the strength of each presentation and recommend possible next steps for further research and collection efforts.

HIGH-IMPACT/LOW-PROBABILITY ANALYSIS

Highlights a seemingly unlikely event that would have major policy consequences if it happened.

WHEN TO USE

High-Impact/Low-Probability Analysis is a contrarian technique that sensitizes analysts to the potential impact of seemingly low probability events that would have major repercussions on US interests. Using this technique is advisable when analysts and policymakers are convinced that an event is unlikely but have not given much thought to the consequences of its occurrence. In essence, this can be a warning that the intelligence and policy communities must be alert to an unexpected but not impossible event. For example, the fall of the Shah, the collapse of the Soviet Union, and the reunification of Germany were all considered low probability events at one time; however, analysts might have benefited from considering the consequences of such events and how they might plausibly have come about.

VALUE ADDED

Mapping out the course of an unlikely, yet plausible, event can uncover hidden relationships between key factors and assumptions; it also can alert analysts to oversights in the mainstream analytic line. In addition, an examination of the "unthinkable" allows analysts to develop signposts that may provide early warning of a shift in the situation. By periodically reviewing these indicators an analyst is more likely to counter any prevailing mind-set that such a development is highly unlikely.

THE METHOD

If there is a strongly held view that an event is unlikely, then postulating precisely the opposite should not be difficult.

- Define the high-impact outcome clearly. This process is what will justify examining what most analysts believe to be a very unlikely development.
- Devise one or more plausible explanations for or "pathways" to the low probability outcome. This should be as precise as possible, as it can help identify possible indicators for later monitoring.
- Insert possible triggers or changes in momentum if appropriate. These can be natural disasters, sudden health problems of key leaders, or new economic or political shocks that might have occurred historically or in other parts of the world.
- Brainstorm with analysts having a broad set of experiences to aid the development of plausible but unpredictable triggers of sudden change.
- Identify for each pathway a set of indicators or "observables" that would help you anticipate that events were beginning to play out this way.
- Identify factors that would deflect a bad outcome or encourage a positive outcome.

High Impact of a Low-Probability Event: Pearl Harbor

". . . So far as relations directly between the United States and Japan are concerned, there is less reason today than there was a week ago for the United States to be apprehensive lest Japan make "war" on this country.

Were it a matter of placing bets, the undersigned would give odds of five to one that the United States and Japan will not be at "war" on or before December 15; would wager three to one that the United States and Japan will not be at 'war' on or before the 15th of January (i.e, seven weeks from now); would wager even money that the United States and Japan will not be at "war" on or before March 1 (a date more than 90 days from now) . . ."

—State Department Special Assessment, 27 November 1941

High-Impact/Low-Probability Analysis on 9/11

The 9/11 Commission report includes examination of speculative analysis that was provided to senior policymakers highlighting what were thought to be highly unlikely scenarios that would have a very high impact. One of those items was the 6 August 2001 President's Daily Brief, which stated:

Al-Qai'da members—including some who are US citizens—have resided in or traveled to the US for years, and the group apparently maintains a support structure that could aid attacks. Two al-Qai'da members found guilty in the conspiracy to bomb our embassies in East Africa were US citizens, and a senior EIJ [Egyptian Islamic Jihad] member lived in California in the mid-1990s.

- A clandestine source said in 1998 that a Bin Ladin cell in New York was recruiting Muslim-American youth for attacks.

We have not been able to corroborate some of the more sensational threat reporting, such as that from a service in 1998 saying that Bin Ladin wanted to hijack a US aircraft to gain the release of "Blind Shaykh" 'Umar Abd al-Rahman and other US-held extremists.

—9/11 Commission Report, declassified and approved for release 10 April 2004.

"WHAT IF?" ANALYSIS

Assumes that an event has occurred with potential (negative or positive) impact and explains how it might come about.

WHEN TO USE

"What If?" analysis is another contrarian technique for challenging a strong mind-set that an event will not happen or that a confidently made forecast may not be entirely justified. It is similar to a High-Impact/Low-Probability analysis, but it does not dwell on the consequences of the event as much as it accepts the significance and moves directly to explaining how it might come about.

VALUE ADDED

By shifting the focus from whether an event could occur to how it may happen, analysts allow themselves to suspend judgment about the likelihood of the event and focus more on what developments—even unlikely ones—might enable such an outcome. An individual analyst or a team might employ this technique and repeat the exercise whenever a critical analytic judgment is made.

Using this technique is particularly important when a judgment rests on limited information or unproven assumptions. Moreover, it can free analysts from arguing about the probability of an event to considering its consequences and developing some indicators or signposts for its possible emergence. It will help analysts address the impact of an event, the factors that could cause—or alter—it, and likely signposts that an event is imminent.

A "What If?" analysis can complement a difficult judgment reached and provide the policymaker a thoughtful caution to accepting the conventional wisdom without considering the costs and risks of being wrong. This can help decision-makers consider ways to hedge their bets, even if they accept the analytic judgment that an event remains unlikely.

THE METHOD

Like other contrarian methods, "What If?" analysis must begin by stating clearly the conventional analytic line and then stepping back to consider what alternative outcomes are too important to dismiss, even if unlikely. Brainstorming over a few days or weeks can develop one or more plausible scenarios by which the unlikely event occurs:

- Assume the event has happened.
- Select some triggering events that permitted the scenario to unfold to help make the "what if" more plausible; for example, analysts might postulate the death of a leader, a natural disaster, or some economic event that would start a chain of other events.
- Develop a chain of argumentation based as much on logic as evidence to explain how this outcome could have come about.
- "Think backwards" from the event in concrete ways–that is, specifying what must actually occur at each stage of the scenario is often very useful.
- Identify one or more plausible pathways or scenarios to the unlikely event; very often more than one will appear possible.
- Generate a list of indicators or "observables" for each scenario that would help to detect the beginnings of the event.
- Consider the scope of the positive and negative consequences of each scenario and their relative impacts.
- Monitor the indicators developed on a periodic basis.

"What If?" Analysis: An Unlikely Outcome in Yugoslavia, 1990.

The possibility of muddling through is very low. In the unlikely event that it happens, this is what it would look like.

Memories of the internecine civil war during World War II and fear of another destructive conflict would lead the two most numerous South Slav people—Serbs and Croats—to reach some political accommodation. A compromise that preserves Yugoslavia would include:

- Basic principles:
  - -No change in existing Republic borders.
  - -No change in Yugoslavia's existing international status.
  - -Mutually recognized sovereignty of each republic

- Confederal institutions:
  - -A single foreign ministry, to which diplomatic representatives would be accredited.
  - -A central military organization with a joint General Staff responsible for planning.
  - -A central bank, determining macroeconomic policy, a common currency,

- Powers reserved to republics.
  - -Veto over actions of the Confederal Authority.
  - -Control of internal security, including guarantee of minority rights.
  - -Operational control over some or all military units stationed on the republic's territory.
  - -Raising taxes and allocating funds to discharge mutually agreed confederal responsibilities.

Only the Serbs can open the door to a confederal Yugoslavia, and Serbia's leader, Slobodan Milosevic, holds the key. Some observers felt there are pressures on him to try. If he does not, he would give his opponents the leverage to remove him. The potential penalties of failure to compromise would be too great, in this view, for the peoples and leaders of Yugoslavia to forgo every effort to find a compromise.

—*Excerpts from the declassified* NIE: Prospects for Yugoslavia*, October 1990.*

BRAINSTORMING

An unconstrained group process designed to generate new ideas and concepts.

WHEN TO USE

Brainstorming is a widely used technique for stimulating new thinking and it can be applied to virtually all of the other structured analysis techniques as an aid to thinking. Typically, analytic will brainstorm when they begin a project to help generate a range of hypotheses about their issue.

Brainstorming, almost by definition, involves a group of analysts meeting to discuss a common challenge; a modest investment of time at the beginning or critical points of a project can take advantage of their different perspectives to help structure a problem. This group process allows others to build on an initial idea suggested by a member of the brainstorming session.

An individual analyst also can brainstorm to produce a wider range of ideas than a group might generate, without regard for other analysts' egos, opinions, or objections. However, an individual will not have the benefit of others' perspectives to help develop the ideas as fully. Moreover, an individual may have difficulty breaking free of his or her cognitive biases without the benefit of a diverse group.

VALUE ADDED

This technique can maximize creativity in the thinking process, force analysts to step outside their normal analytic mind-sets, and suspend their typical "good judgment" about the practicality of ideas or approaches. More generally, brainstorming allows analysts to see a wider range of factors that might bear on the topic than they would otherwise consider. Analysts typically censor out ideas that seem farfetched, poorly sourced, or seemingly irrelevant to the question at hand. Brainstorming gives permission to think more radically or "outside the box." In particular, it can spark new ideas, ensure a comprehensive look at a problem or issues, raise unknowns, and prevent premature consensus around a single hypothesis.

THE METHOD

Paradoxically, brainstorming should be a very structured process to be most productive. An unconstrained, informal discussion might produce some interesting ideas, but usually a more systematic process is the most effective way to break down mind-sets and produce new insights. In particular, the process involves a divergent thinking phase to generate and collect new ideas and insights, followed by a convergent phase in which ideas are grouped and organized around key concepts. Some of the simple rules to be followed include:

- Never censor an analyst's ideas no matter how unconventional they might sound.
- Rather find out what prompted the thought, as it might contain the seeds of an important connection between the topic and an unstated assumption.
- Give yourself enough time to do brainstorming correctly. It usually takes one hour to set the "rules" of the game, get the group comfortable, and exhaust the conventional wisdom on the topic. Only then will the truly creative ideas begin to emerge.
- Involve at least one "outsider" in the process—that is, someone who does not share the same educational background, culture, technical knowledge or mind-set as the core group but has some familiarity with the topic.

A two-phase, twelve-step, structured process is often used to get the most out of the brainstorming sessions:

Brainstorming and Divergent Thinking: Perspectives of an Experienced Practitioner

". . . First, leave rank at the door and focus on "a democracy of ideas." Thoughts from experts, senior officers, and supervisors are of course, valuable and welcome, but such experts are not permitted to cut off debate by citing their seniority. In fact, it pays to invite junior officers as well as senior ones who are not involved directly in working the issue under discussion. Some of the most creative ideas at brainstorming sessions frequently come from relatively junior people who can look at a problem with fresh perspective, or from senior ones who are not experts on the issue.

Second, make sure there is no official analytic line. One of the most significant blocks to new thinking is the presence of a long held analytic line that analysts—and even more so managers—are reluctant to change. Rather than trying to fit ideas into the framework of "what we've said before," analysts need to feel free to go wherever bits of the evidence and informed supposition take them. They must feel free to throw out seemingly strange but plausible ideas that might be based on historical precedent and instinct rather than on concrete information. Facilitators can stimulate this process by deliberately posing an alternative outcome to a problem that differs starkly from the accepted analysis or by proposing a contrary way to think about an issue.

Third, don't permit killer phrases like "that would not work" or "that could not happen" to be voiced out loud. Effective brainstorming starts with ideas and possibilities, not with practicalities and self-imposed obstacles to fresh perspectives. Force the group to get as wide a range of ideas out for discussion as possible. At some point, a set of ideas might be winnowed down and subject to tests of workability, but that comes later—not during brainstorming.

Fourth, keep the brainstorming session to no more than 90 minutes. There is no hard and fast rule, but somewhere between 60 and 90 minutes, the idea stream starts to dry up, people repeat themselves, and jokes replace creative ideas.

Fifth, record ideas in a visible way. Lots of people take notes at brainstorming sessions for their own use, and that is good. We have found it valuable to have someone jot down the ideas presented on large paste-a-note sheets that we put on the walls. This allows participants in brainstorming sessions to react to ideas generated earlier. Moreover, analysts are encouraged to participate in such exercises if they see their own ideas put down in writing. Having a notional record of brainstorming also helps the analyst who ends up writing a report based on the discussion. Ideas that may not be used in one report are invariably put to use later, so it is good to have a record of them . . ."

Divergent Thinking Phase:

- Distribute “Post-It” notes and pens or markers to all participants. Typically, 10-12 people works best.
- Pose the problem in terms of a “focal question.” Display it in one sentence on a large easel or whiteboard.
- Ask the group to write down responses to the question, using key words that will fit on the small “Post-It” note.
- Stick all the notes on a wall for all to see—treat all ideas the same.
- When a pause follows the initial flow of ideas, the group is reaching the end of their conventional thinking and the new divergent ideas are then likely to emerge.
- End the “collection stage” of the brainstorming after two or three pauses.

Convergent Thinking Phase:

- Ask the participants as a group to rearrange the notes on the wall according to their commonalities or similar concepts. No talking is permitted. Some notes may be moved several times as notes begin to cluster. Copying some notes is permitted to allow ideas to be included in more than one group.
- Select a word or phrase that characterizes each grouping or cluster once all the notes have been arranged.
- Identify any notes that do not easily fit with others and consider them either useless noise or the beginning of an idea that deserves further attention.
- Assess what the group has accomplished in terms of new ideas or concepts identified or new areas that need more work or further brainstorming.
- Instruct each participant to select one or two areas that deserve the most attention. Tabulate the votes.
- Set the brainstorming group’s priorities based on the voting and decide on the next steps for analysis.

OUTSIDE-IN THINKING

Used to identify the full range of basic forces, factors, and trends that would indirectly shape an issue.

WHEN TO USE

Analysts find this technique most useful at the conceptualization of an analytic project, when the goal is to identify all the critical, external factors that could influence how a particular situation will develop. It would work well for a group of analysts responsible for a range of functional and/or regional issues. When assembling a large database that must identify a number of information categories or database fields, this technique can aid in visualizing the entire set of categories that might be needed in a research effort. Often analysts realize only too late that some additional information categories will be needed and then must go back and review all previous files and recode the data. With a modest amount of effort, "Outside-in Thinking" can reduce the risk of missing important variables early in the analytic process.

VALUE ADDED

Most analysts spend their time concentrating on familiar factors within their field or analytic issue. That is, they think from the "inside"—namely, what they control—out to the broader world. Conversely, "thinking from the outside-in" begins by considering the external changes that might, over time, profoundly affect the analysts' own field or issue. This technique encourages analysts to get away from their immediate analytic tasks (the so-called "inbox") and think about their issues in a wider conceptual and contextual framework. By recasting the problem in much broader and fundamental terms, analysts are more likely to uncover additional factors, an important dynamic, or a relevant alternative hypothesis.

THE METHOD

The process begins by developing a generic description of the problem or the phenomenon under study. Then, analysts should:

- List all the key forces (social, technological, economic, environmental, and political) that could have an impact on the topic, but over which one can exert little influence (e.g., globalization, social stress, the Internet, or the global economy).
- Focus next on key factors over which an actor or policymaker can exert some influence. In the business world this might be the market size, customers, the competition, suppliers or partners; in the government domain it might include the policy actions or the behavior of allies or adversaries.
- Assess how each of these forces could affect the analytic problem.
- Determine whether these forces actually do have an impact on the particular issue based on the available evidence.

RED TEAM ANALYSIS

Models the behavior of an individual or group by trying to replicate how an adversary would think about an issue.

WHEN TO USE

Frequently, analysts face the challenge of forecasting how a foreign leader or decisionmaking group may behave when it is clear that there is a risk of falling into a "mirror-image" problem. That is, analysts can sometimes impute to a foreign actor the same motives, values, or understanding of an issue that they hold. Traditional analysis sometimes assumes that foreign leaders or groups will behave "rationally" and act as the analysts would if faced with the same threats or opportunities. History has shown that foreign leaders often respond differently to events because of different cultural, organizational, or personal experiences.

Red Team analysis tries to consciously place analysts in the same cultural, organizational, and personal setting ("putting them in their shoes") in which the target individual or group operates. Whereas analysts normally work from the position of the "blue" (friendly forces), a "red" team of analysts attempts to work in the environment of the hostile forces.

VALUE ADDED

Like Devil's Advocacy and Team A/Team B techniques, Red Team analysis is aimed at freeing the analyst from the prison of a well-developed mind-set; in this case, the analyst's own sense of rationality, cultural norms, and personal values. Whereas analysts usually operate as "observers" of a foreign adversary, the Red Team technique transforms the analyst into an "actor" operating within the adversary's culture and political milieu. This form of "role playing" is useful when trying to replicate the mind-set of authoritarian leaders, terrorist cells, or other non-Western groups that operate under very different codes of behavior or motivations. Often this technique can introduce new or different stimuli that might not have been factored into traditional analysis—such as the target's familial ties or the international political, economic, and military pressures felt by the individual. For example, Red Team participants might ask themselves: "What would my peers, family, or tribe expect me to do? Alternatively, a Red Team analyst might pose the question to his colleagues: "How do we perceive the external threats and opportunities?" Finally, the Red Team technique can factor into its analysis the way in which personal power and status might influence a target's behavior.

THE METHOD

On issues that lend themselves to Red Team analysis, a manager needs to build a team of experts with in-depth knowledge of the operating environment, the target's personality, and the style of thinking used. The team should be populated not just with those who understand the language, but also with people who might have experienced the culture, share the ethnic background, or have worked in a similar operational environment. Once established and separated from traditional analysis, the team members should:

- Put themselves in the adversary's circumstances and react to foreign stimuli as the target would.
- Develop a set of "first-person" questions that the adversary would ask, such as: "How would I perceive incoming information; what would be my personal concerns; or to whom would I look for an opinion?"
- Draft a set of policy papers in which the leader or group makes specific decisions, proposes recommendations, or lays out courses of actions. The more these papers reflect the cultural and personal norms of the target, the more they can offer a different perspective on the analytic problem.

A Red Team Perspective
Iran's Military Strategy Vis-a-vis the United States

". . . The United States and Israel may be contemplating military operations against Iran, as per recent media reports . . . A week-long combined air and ground maneuver has just concluded in five of the southern and western provinces of Iran, mesmerizing foreign observers, who have described as 'spectacular' the massive display of high-tech, mobile operations, including rapid-deployment forces relying on squadrons of helicopters, air lifts, missiles, as well as hundreds of tanks and tens of thousands of well-coordinated personnel using live munitions.

Learning from both the 2003 Iraq war and Iran's own previous experiences of the 1980-88 war with Iraq and the 1987-88 confrontation with US forces in the Persian Gulf, Iranians have focused on the merits of a fluid and complex defensive strategy that seeks to take advantage of certain weaknesses in the US military superpower while maximizing the precious few areas where they may have the upper hand, e.g.; numerical superiority in ground forces, guerrilla tactics, terrain, etc.

Any US attack on Iran will likely be met first and foremost by missile counter-attacks engulfing the southern Persian Gulf states playing host to US forces, as well as any other country—e.g., Azerbaijan, Iraq, or Turkey allowing their territory or airspace to be used against Iran. The rationale for this strategy is precisely to pre-warn Iran's neighbors of the dire consequences, with potential debilitating impacts on their economies for a long time, should they become accomplices of foreign invaders of Iran.

Another key element of Iran's strategy is to "increase the arch of crisis" in places such as Afghanistan and Iraq, where it has considerable influence, to undermine the United States' foothold in the region, hoping to create a counter-domino effect wherein instead of gaining inside Iran, the US would actually lose territory partly as a result of thinning its forces and military 'overreach.'

Iran's counter-psychological warfare, on the other hand, seeks to take advantage of the 'death-fearing' American soldiers who typically lack a strong motivation to fight wars not necessarily in defense of the homeland. A war with Iran would definitely require establishing the draft in the US, without which it could not possibly protect its flanks in Afghanistan and Iraq.

There is a sense of national-security siege in Iran these days, in light of a tightening "security belt" by the US benefiting from military bases in Iraq, Turkey, Azerbaijan, Uzbekistan, Tajikistan, Kyrgyzstan, as well as Kuwait, Saudi Arabia, Qatar, Bahrain, Oman, and the island-turned garrison of Diego Garcia. From Iran's vantage point, the US, having won the Cold War, has turned into a 'leviathan unhinged' capable of manipulating and subverting the rule of international law and the United Nations with impunity, thus requiring a sophisticated Iranian strategy of deterrence, that, in the words of certain Iranian media pundits, would even include the use of nuclear weapons . . ."

—Excerpts from Kaveh L. Afrasiabi (Tehran University), "How Iran Will Fight Back," cited in Asia Times Online Ltd., 2004.

Red Team analysis is not easy to conduct. It requires significant time to develop a team of qualified experts who can think like the adversary. The team has to distance itself from the normal analysis and work as though living in the target's world. Without a sophisticated understanding of the culture, operational environment, and personal histories of the foreign group, analysts will not be able to behave or think like the enemy. Analysts can never truly escape their own experiences and mind-sets, but this technique can at least prevent them from falling into "mirror-imaging" unconsciously.

The most novel feature of Red Team analysis is its presentation.

- The analysis is often in a "first person" format—that is, drafted as memos to or from a leader or group.
- Red Team analysis avoids the use of caveats or qualifications and assumes that the recipient understands that the paper is aimed more at provoking thought or challenging the conventional understanding of how an adversary thinks.
- Such papers are rarely coordinated among other experts and do not purport to represent the consensus view on an issue.

Red Team papers do not plot out all possible courses of action but seek to give a prediction based on the target's special personal, organizational, or cultural experiences.

ALTERNATIVE FUTURES ANALYSIS

Systematically explores multiple ways a situation can develop when there is high complexity and uncertainty.

WHEN TO USE

Alternative futures analysis (often referred to as "scenarios") is most useful when a situation is viewed as too complex or the outcomes as too uncertain to trust a single outcome assessment. First, analysts must recognize that there is high uncertainty surrounding the topic in question. Second, they, and often their customers, recognize that they need to consider a wide range of factors that might bear on the question. And third, they are prepared to explore a range of outcomes and are not wedded to any preconceived result. Depending on how elaborate the futures project, the effort can amount to considerable investment in time, analytic resources, and money. A team of analysts can spend several hours or days organizing, brainstorming, and developing multiple futures; alternatively, a larger-scale effort can require preparing a multi-day workshop that brings together participants (including outside experts). Such an undertaking often demands the special skills of trained scenario-development facilitators and conferencing facilities.

This technique is a sharp contrast to contrarian techniques, which try to challenge the analysts' high confidence and relative certitude about an event or trend. Instead, multiple futures development is a divergent thinking technique that tries to use the complexity and uncertainty of a situation to describe multiple outcomes or futures that the analyst and policymaker should consider, rather than to predict one outcome.

VALUE ADDED

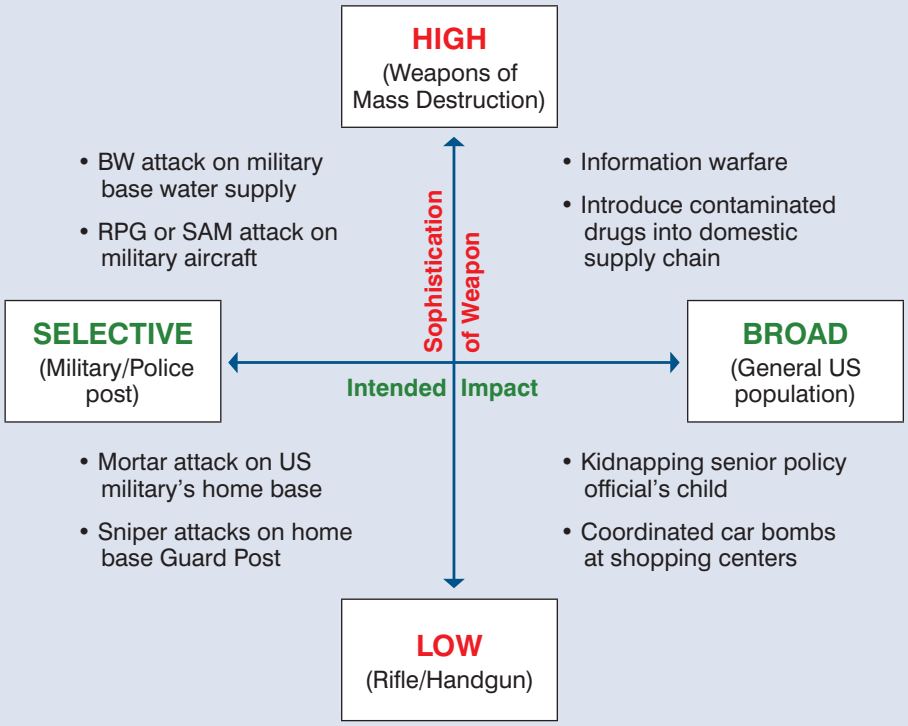
Alternative futures analysis is extremely useful in highly ambiguous situations, when analysts confront not only a lot of "known unknowns" but also "unknown unknowns." What this means is that analysts recognize that there are factors, forces, and dynamics among key actors that are difficult to identify without the use of some structured technique that can model how they would interact or behave. As the outcomes are not known prior to the futures exercise, analysts must be prepared for the unexpected and willing to engage in a more free-wheeling exchange of views than typically occurs in order to "imagine the future." Given the time and resources involved, scenario analysis is best reserved for situations that could potentially pose grave threats or otherwise have significant consequences.

From past experience, analysts have found that involving policymakers in the alternative futures exercise is the most effective way to communicate the results of this exploration of alternative outcomes and sensitize them to key uncertainties. Most participants find the process of developing such scenarios as useful as any finished product that attempts to capture the results of the exercise. Analysts and policymakers can benefit from this technique in several ways:

- It provides an effective means of weighing multiple unknown or unknowable factors and presenting a set of plausible outcomes.
- It can help to bound a problem by identifying plausible combinations of uncertain factors.
- It provides a broader analytic framework for calculating the costs, risks, and opportunities presented to policymakers by different outcomes.

> *"The future is plural."*
>
> —Peter Schwartz, author of *The Art of the Long View* and a widely acclaimed scenario developer.

Hypothetical Threats to the Homeland: Using Spectrums to Define Potential Targets



A Futures Exercise. The graphic captures four potential futures to understand how foreign insurgents might carry out an attack on the United States. A brainstorming exercise helped analysts identify two key uncertainties (the sophistication of weapons used by the insurgents and the intended impact of the attack) and arrayed these factors on a graph as the "x" and "y" axes. The four resulting quadrants in the 2 x 2 matrix allowed analysts to visualize potential targets from the various combinations (low to high sophistication of weapons and selective to broad intended impact of an attack). For example, if a group possessed highly sophisticated weapons and intended a broad attack on the United States, potential targets could include computer networks and domestic drug supplies. Having filled in a quadrant, analysts can then turn to devising likely indicators or signposts of such a future.

- It aids analysts and policymakers in anticipating what otherwise would be surprising developments by forcing them to challenge assumptions and consider possible "wild cards" or discontinuous events.

- It generates indicators to monitor for signs that a particular future is becoming more or less likely, so that policies can be reassessed.

THE METHOD

Although there are a variety of ways to develop alternative futures, the most common approach used in both the public and private sectors involves the following steps:

- Develop the "focal issue" by systematically interviewing experts and officials who are examining the general topic.

- Convene a group of experts (both internal and external) to brainstorm about the forces and factors that could affect the focal issue.

- Select by consensus the two most critical and uncertain forces and convert these into axes or continua with the most relevant endpoints assigned.

- Establish the most relevant endpoints for each factor; e.g., if economic growth were the most critical, uncertain force, the endpoints could be "fast" and "slow" or "transformative" and "stabilizing" depending on the type of issue addressed.

- Form a futures matrix by crossing the two chosen axes. The four resulting quadrants provide the basis for characterizing alternative future worlds.

- Generate colorful stories that describe these futures and how they could plausibly come about. Signposts or indicators can then be developed.

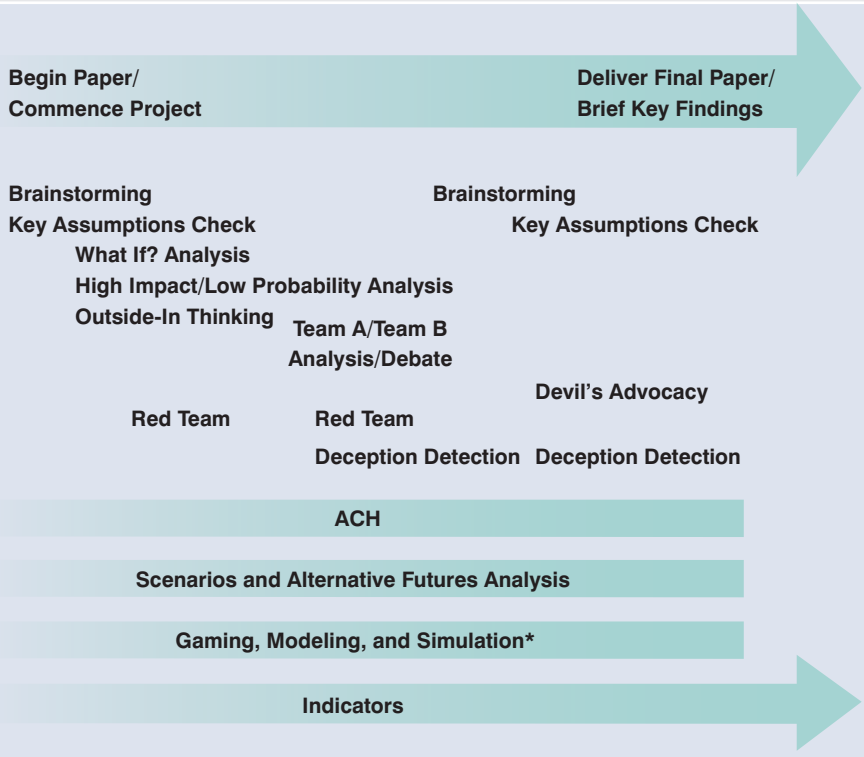
Participants, especially policymakers, can then consider how current decisions or strategies would fare in each of the four worlds and identify alternative policies that might work better either across all the futures or in specific ones. By anticipating alternative outcomes, policymakers have a better chance of either devising strategies flexible enough to accommodate multiple outcomes or of being prepared and agile in the face of change.

These structured analytic techniques can be used in a variety of ways when analysts begin a new assessment. Some can be used equally effectively at multiple points in the process and can promote an analyst's ability to keep an open mind, to consider multiple—including highly unlikely—hypotheses, to challenge conventional wisdom, and to assess the impact of important information gaps or deception on analytic judgments and confidence levels. The Timeline for Using Analytic Techniques provides some thoughts on when to use one or more of them during the course of an analyst's research and writing.

Starting Out

At the beginning of an analytic project, analysts are always wise to consider brainstorming and assumptions checks to insure that important factors are not being missed or taken for granted. Similarly, outside-in-thinking can sometimes put an analytic project into a broader international context, in which factors outside the lead analyst's area of responsibility might impact on his or her analytic judgments. For instance, economic assumptions about the price of oil might be key to a regional political analyst's understanding the prospects for political stability in an oil-exporting

A Timeline for Using Analytic Techniques Throughout an Analytic Project



*Gaming, Modeling, and Simulation are among the more sophisticated techniques taught in a more advanced analytic methods course and usually require substantial commitments of analyst time and corporate resources.

country or a underdeveloped country entirely dependent on expensive energy imports. A High Impact/Low Probability assessment can also sensitize analysts early on to the significance of dramatic events that might affect their analytic lines.

Some techniques like Indicators and Signposts or Analysis of Competing Hypotheses (ACH) can be useful throughout a project and revisited periodically as new information is absorbed and analyzed. ACH, in particular, is a good tool to use throughout a project to prevent premature closure and to highlight evidence that is most "discriminating" in making an analytic argument. Alternative Futures analysis is similarly useful at the beginning of a project, but can amount to the structure for the entire project.

Hypothesis Testing

As an analytic project takes shape, and hypotheses are being formed about the key intelligence question, it can be appropriate to use one or another contrarian technique to challenge the conventional analytic line that is being developed. If the assessment contains strong judgments about an adversary's behavior, then challenging this view with a "Red Team" effort might be a good corrective to too much of a rational actor approach. Also, a review of intelligence gaps at this juncture can also help give the analysts a better degree of confidence in the information base and judgments reached in the assessment.

A Final Check

As the assessment is being finalized, it can still be useful to review key assumptions as a sanity check on the underlying logic of the analysis. A brainstorming session also may be helpful to insure that no plausible hypothesis has been dismissed or left unaddressed. If a firm consensus has formed around an analytic line and has not been seriously questioned in some time, then a Devil's Advocacy exercise could be useful. Analysts might also use a final review to decide if they have identified a list of key indicators for future developments. This can be an important guide to include in the assessment as a way to track future developments and monitor whether the analytic judgments reached are being realized or in need of revision.

Graham Allison, *Essence of Decision*: *Explaining the Cuban Missile Crisis*: Examines the Kennedy Administration's decisionmaking style from alternative perspectives of the "rational actor," "organizational actor," and "bureaucratic politics" models.

Max Bazerman and Michael D. Watkins, *Predictable Surprises: The Disasters You Should Have Seen Coming and How To Prevent Them*. Examines the cognitive, organizational and political causes of some predictable surprises and outlines steps to overcome them.

Richard Betts, *Surprise Attack: Lessons for Defense Planning*. Explains why surprise attacks historically have succeeded and argues that the US needs strategies for avoiding surprise or at least reducing their consequences. Uses examples from World War II, Korea, and the Middle East.

Josh Epstein and Rob Axtell, *Sugarscape: Creating Artificial Societies from the Ground Up*. Develops a very simple agent-based model of a silicon-based society and then does simulations of various social, economic and political phenomena, including conflict.

The Joint Military Intelligence College supports and encourages research on intelligence issues that distills lessons and improves support to policy-level and operational consumers.

This series of Occasional Papers presents the work of faculty, students and others whose research on intelligence issues is supported or otherwise encouraged by the Joint Military Intelligence College through its Office of Applied Research. Occasional Papers are distributed to Department of Defense schools and to the Intelligence Community, and unclassified papers are available to the public through the National Technical Information Service (www.ntis.gov).

Proposed manuscripts for these papers are submitted for consideration to the Applied Research Editorial Board. Papers undergo review by senior officials in Defense, Intelligence, and occasionally civilian academic or business communities. Manuscripts or requests for additional copies of Occasional Papers should be addressed to Defense Intelligence Agency, Joint Military Intelligence College, Office of Applied Research, MCE, Bolling AFB, Washington, DC 20340-5100.

INTELLIGENCE ESSENTIALS FOR EVERYONE

Preface

The "importance of understanding" has become almost an obsession with significant portions of American business. There remain, however, many companies that attempt to operate as they traditionally have in the past — placing great faith in the owner's or manager's judgment as to what is required to remain competitive.

In this paper, the author has articulated clearly the fundamentals of sound intelligence practice and has identified some guidelines that can lead toward creation of a solid intelligence infrastructure. These signposts apply both to government intelligence and to business. Good intelligence should always be based on validated requirements, but it may be derived from a wide variety of sources, not all of which are reliable.

Understanding the needs of the consumer and the sources available enable an analyst to choose the correct methodology to arrive at useful answers. The author has laid out in clear, concise language a logical approach to creating an infrastructure for government and business. Every system will have flaws but this discussion should help the reader minimize those weaknesses. It is an important contribution to the education of government and business intelligence professionals.

James A. Williams, LTG, U.S. Army (Ret.)
Former Director, Defense Intelligence Agency

INTELLIGENCE ESSENTIALS FOR EVERYONE

Foreword

Decades of government intelligence experience and reflection on that experience are captured in this primer. Ms. Krizan combines her own findings on best practices in the intelligence profession with the discoveries and ruminations of other practitioners, including several Joint Military Intelligence College instructors and students who preceded her. Many of the selections she refers to are from documents that are out of print or have wrongly been assigned to a dustbin.

This primer reviews and reassesses Intelligence Community best practices with special emphasis on how they may be adopted by the private sector. The government convention of referring to intelligence users as "customers" suggests by itself the demonstrable similarities between government intelligence and business information support functions.

The genesis for this study was the author's discovery of a need to codify for the Intelligence Community certain basic principles missing from the formal training of intelligence analysts. At the same time, she learned of requests from the private sector for the same type of codified, government best practices for adaptation to the business world. As no formal mechanism existed for an exchange of these insights between the public and private sectors, Ms. Krizan developed this paper as an adjunct to her Master's thesis, *Benchmarking the Intelligence Process for the Private Sector.* Her thesis explores the rationale and mechanisms for benchmarking the intelligence process in government, and for sharing the resultant findings with the private sector.

The author and editor wish to acknowledge the constructive comments of two reviewers from the business community, representing the Amoco Corporation and DeGenaro and Associates, Inc. of Sarasota, Florida.

Comments on this paper are welcome, and should be directed to the Office of Applied Research, MCE-2, Joint Military Intelligence College, DIAC, Bolling AFB, Washington, DC 20340-5100. Telephone (202) 231-4193; DSN 428-4193; e-mail *AFswerg@dia.osis.gov.*

Dr. Russell G. Swenson, Editor and Director, Office of Applied Research

PROLOGUE: INTELLIGENCE SHARING IN A NEW LIGHT

Education is the cheapest defense of a nation.
— Edmund Burke, 18th-century British philosopher

National Intelligence Meets Business Intelligence

This intelligence primer reflects the author's examination of dozens of unclassified government documents on the practice of intelligence over a period of nearly seven years. For the national security Intelligence Community (IC), it represents a concise distillation and clarification of the national intelligence function. To the private sector, it offers an unprecedented translation into lay terms of national intelligence principles and their application within and potentially outside of government.[1] Whereas "intelligence sharing" has traditionally been a government-to-government transaction, the environment is now receptive to government-private sector interaction.

The widespread trend toward incorporating government intelligence methodology into commerce and education was a primary impetus for publishing this document. As economic competition accelerates around the world, private businesses are initiating their own "business intelligence" (BI) or "competitive intelligence" services to advise their decisionmakers. Educators in business and academia are following suit, inserting BI concepts into professional training and college curricula.[2]

Whereas businesses in the past have concentrated on knowing the market and making the best product, they are shifting their focus to include knowing, and staying ahead of, competitors. This emphasis on competitiveness requires the sophisticated production and use of carefully analyzed information tailored to specific users; in other words, intelligence. But the use of intelligence as a strategic planning tool, common in government, is a skill that few companies have perfected.[3]

Although BI practitioners refer to the national security model of intelligence, they do not seek to conduct secret intelligence operations, which are limited by law to government

---

[1] For the purpose of this study, the author includes in national security intelligence those analogous activities conducted by law enforcement personnel at the federal, state, and local levels. Readers seeking further information on law enforcement applications of intelligence may wish to read Marilyn Peterson, *Applications in Criminal Analysis* (Westport, Connecticut: Greenwood Press, 1994). An additional resource is the International Association of Law Enforcement Intelligence Analysts. Local IALEIA chapters are listed on the Association's web site: http://www.ialeia.org.

[2] An authoritative guide to business intelligence practices is found in Larry Kahaner, *Competitive Intelligence: From Black Ops to Boardrooms — How Businesses Gather, Analyze and Use Information to Succeed in the Global Marketplace* (New York, NY: Simon and Schuster, 1996).

[3] Richard D'Aveni, "Hypercompetition," briefing to SCIP Conference, Alexandria, VA, 28 March 1996.

authorities. The Society of Competitive Intelligence Professionals (SCIP), headquartered in the Washington, DC area, is an international organization founded in 1986 to "assist members in enhancing their firms' competitiveness through a greater... understanding of competitor behaviors and future strategies as well as the market dynamics in which they do business."[4] SCIP's code of conduct specifically promotes ethical and legal BI practices.[5] The main focus of "collection" is on exploiting on-line and open-source information services, and the theme of "analysis" is to go beyond mere numerical and factual information, to interpretation of events for strategic decisionmaking.[6]

Large corporations are creating their own intelligence units, and a few are successful at performing analysis in support of strategic decisionmaking. Others are hiring BI contractors, or "out-sourcing" this function. However, the majority of businesses having some familiarity with BI are not able to conduct rigorous research and analysis for value-added reporting. According to University of Pittsburgh professor of Business Administration John Prescott, no theoretical framework exists for BI. He believes that most studies done lack the rigor that would come with following sound research-design principles. By his estimate, only one percent of companies have a research-design capability exploitable for BI applications.[7] At the same time, companies are increasingly opting to establish their own intelligence units rather than purchasing services from BI specialists. The implication of this trend is that BI professionals should be skilled in both intelligence and in a business discipline of value to the company.[8]

On the other hand, as businesses come to appreciate the value of intelligence about their competitors, they are increasingly realizing their own vulnerability to similar scrutiny. The private sector can therefore benefit from IC expertise in disciplines complementary to active intelligence production, namely defensive measures. The whole concept of openness regarding intelligence practices may hinge upon the counter-balancing effect of self-defense, particularly as practiced through information systems security (INFOSEC) and operations security (OPSEC).[9] Because the IC seeks to be a world leader in INFOSEC and OPSEC as well as intelligence production, defensive measures are an appropriate topic for dialogue between the public and private sectors.

The U.S. government INFOSEC Manual sums up the relationship between offense and defense in a comprehensive intelligence strategy in this way:

> In today's information age environment, control of information and information technology is vital. As the nation daily becomes more dependent on

9 These concepts are addressed in Part IX.

> networked information systems to conduct essential business, including military operations, government functions, and national and international economic enterprises, information infrastructures are assuming increased strategic importance. This has, in turn, given rise to the concept of information warfare (INFOWAR) — a new form of warfare directed toward attacking (offensive) or defending (defensive) such infrastructures.[10]

Giving citizens the tools they need to survive INFOWAR is one of the IC's explicit missions. This intelligence primer can assist that mission by offering a conceptual and practical "common operating environment" for business and government alike.[11]

Assessing and Exchanging Best Practices

In documenting the essentials of intelligence, this primer is an example of *benchmarking*, a widely used process for achieving quality in organizations, the use of which is a criterion for the business world's Malcolm Baldrige National Quality Award.[12] Benchmarking normally assesses best professional practices, developed and refined through experience, for carrying out an organization's core tasks.[13] An additional aim of benchmarking is to establish reciprocal relationships among best-in-class parties for the exchange of mutually beneficial information.[14] Because the IC is the *de facto* functional leader in the intelligence profession, and is publicly funded, it is obligated to lead both the government and private sector toward a greater understanding of the intelligence discipline.

In the mid-1990s, as national intelligence agencies began to participate in international benchmarking forums, individuals from the private sector began to request practical information on the intelligence process from IC representatives. The requestors were often participants in the growing BI movement and apparently sought to adapt IC methods to their own purposes. Their circumspect counterparts in the government were not prepared to respond to these requests, preferring instead to limit benchmarking relationships to common business topics, such as resource management.[15] Concurrently, the annual SCIP international conference highlighted the needs and capabilities of intelligence departments in the private sector.

[10] National Security Agency, *1995 INFOSEC Manual* (Ft. Meade, MD: NSA, 1995), para. C.1.

[11] Readers in doubt of the need for INFOSEC in the private sector may wish to study the real-world examples of INFOWAR battles and their implications for economic and personal security that author Winn Schwartau reveals in *Information Warfare: Chaos on the Electronic Superhighway*, (New York: Thunder's Mouth Press, 1994).

[12] A useful reference to benchmarking within the U.S. government is Jerry Frankenfield and Melissie Rumizen, *A Guide to Benchmarking* (Fort Meade, MD: National Security Agency (NSA), 12 July 1995). An overview of benchmarking in the private sector can be found in Dean Elmuti, Hanus Kathawaia, and Scott J. Lloyed, "The Benchmarking Process: Assessing Its Value and Limitations," *Industrial Management*, 39, No. 4 (July/August 1997): 12-19.

[13] Elmuti, Kathawaia and Lloyed, 12.

[14] Elmuti, Kathawaia and Lloyed, 13.

[15] Melissie C. Rumizen, Ph.D., Benchmarking Manager, National Security Agency, interview with the author, 2 April 1996.

Demand in the private sector for intelligence skills can be met through the application of validated intelligence practices presented in this document. Conversely, the business-oriented perspective on intelligence can be highly useful to government intelligence professionals. As a BI practitioner explains, every activity in the intelligence process must be related to a requirement, otherwise it is irrelevant.[16] Government personnel would benefit from this practical reminder in every training course and every work center. In the private sector, straying from this principle means wasting money and losing a competitive edge. The consequences of inefficient national intelligence can be costly on an even larger scale.

The basis for an IC benchmarking exchange with the private sector continues to grow. The Society of Competitive Intelligence Professionals is a clearinghouse for the review of private business intelligence practices, and therefore a champion of information sharing. Leading colleges and universities are beginning to offer coursework in intelligence methods, and in many cases intend to expand their offerings. Curriculum exchanges between private sector educators and the IC are encouraged by legislation and by Congressional Commission recommendations,[17] yet little such formal exchange has taken place.

Whereas government practitioners are the acknowledged subject-matter experts in intelligence methodology, the private sector offers a wealth of expertise in particular areas such as business management, technology, the global marketplace, and skills training. Each has valuable knowledge to share with the other, and experience gaps to fill. On the basis of these unique needs and capabilities, the public and private sectors can forge a new partnership in understanding their common responsibilities, and this primer may make a modest contribution toward the exchange of ideas.

The following chapters outline validated steps to operating an intelligence service for both the government and the private sector. In either setting, this document should prove useful as a basic curriculum for students, an on-the-job working aid for practitioners, and a reference tool for experienced professionals, especially those teaching or mentoring others. Although the primer does not exhaustively describe procedures for quality intelligence production or defensive measures, it does offer the business community fundamental concepts that can transfer readily from national intelligence to commercial applications, including competitive analysis, strategic planning and the protection of proprietary information. Universities may incorporate these ideas into their business, political science, and intelligence studies curricula to encourage and prepare students to become intelligence practitioners in commerce or government. For anyone outside of the

national security apparatus, this intelligence primer will shed light on why and how the government spends federal tax dollars on national intelligence.

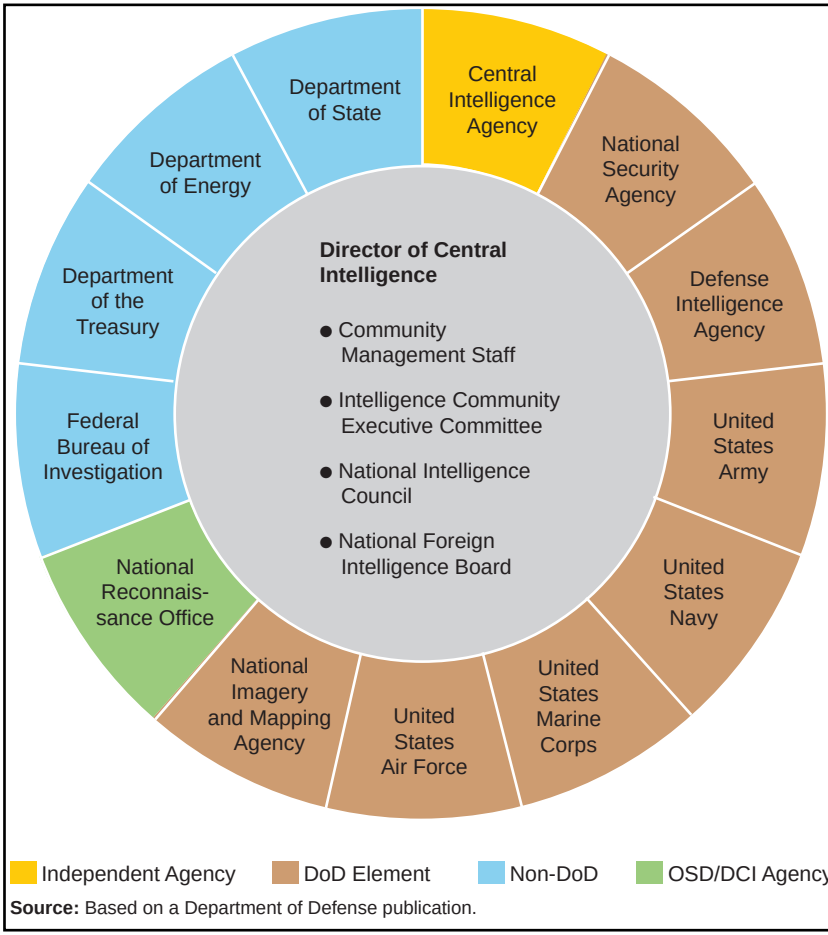

Figure 1: The National Intelligence Community.

PART I
INTELLIGENCE PROCESS

> [I]ntelligence is more than information. It is knowledge that has been specially prepared for a customer's unique circumstances. The word *knowledge* highlights the need for human involvement. Intelligence collection systems produce... data, not intelligence; only the human mind can provide that special touch that makes sense of data for different customers' requirements. The special processing that partially defines intelligence is the continual collection, verification, and analysis of information that allows us to understand the problem or situation in actionable terms and then tailor a product in the context of the customer's circumstances. If any of these essential attributes is missing, then the product remains information rather than intelligence.[18]

The intelligence profession, already well established within government, is growing in the private sector. Intelligence is traditionally a function of government organizations serving the decisionmaking needs of national security authorities. But innovative private firms are increasingly adapting the national security intelligence model to the business world to aid their own strategic planning. Although business professionals may prefer the term "information" over "intelligence," the author will use the latter term to highlight the importance of adding value to information. According to government convention, the author will use the term "customer" to refer to the intended recipient of an intelligence product — either a fellow intelligence service member, or a policy official or decisionmaker. The process of converting raw information into actionable intelligence can serve government and business equally well in their respective domains.

The Intelligence Process in Government and Business

Production of intelligence follows a cyclical *process*, a series of repeated and interrelated steps that add value to original inputs and create a substantially transformed product. That transformation is what distinguishes intelligence from a simple cyclical activity.[19] In government and private sector alike, analysis is the catalyst that converts information into intelligence for planners and decisionmakers.

Although the intelligence process is complex and dynamic, several component functions may be distinguished from the whole. In this primer, components are identified as Intelligence Needs, Collection Activities, Processing of Collected Information, Analysis and Production. To highlight the components, each is accorded a separate Part in this study. These

labels, and the illustration below, should not be interpreted to mean that intelligence is a unidimensional and unidirectional process. "[I]n fact, the [process] is multidimensional, multidirectional, and — most importantly — interactive and iterative."[20]

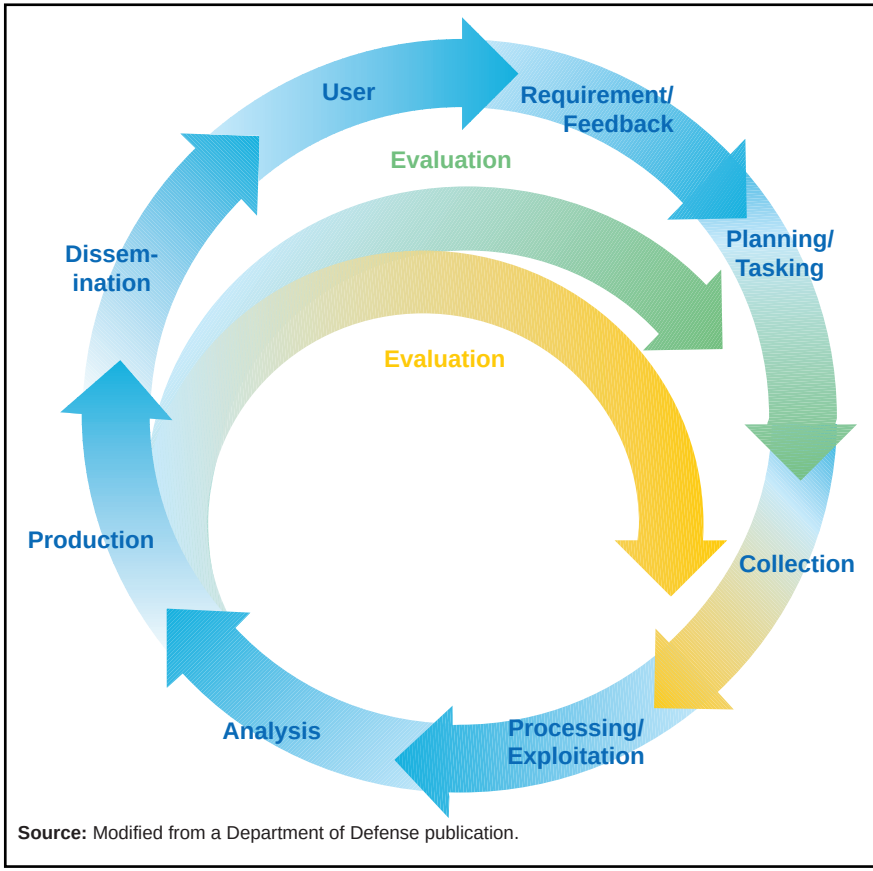

Figure 2: Process of Intelligence Creation and Use.

[20] Douglas H. Dearth, "National Intelligence: Profession and Process," in *Strategic Intelligence: Theory and Application*, eds. Douglas H. Dearth and R. Thomas Goodden, 2d ed. (Washington, DC: Joint Military Intelligence Training Center, 1995), 17.

The purpose of this process is for the intelligence service to provide decisionmakers with tools, or "products" that assist them in identifying key decision factors. Such intelligence products may be described both in terms of their subject content and their intended use.[21]

Table 1: Types of Intelligence Product Categories
Source: adapted from Garst, "Components of Intelligence"

By Subject	By Use
Biographic	Research
Economic	Current
Geographic	Estimative
Military	Operational
Political	Scientific and Technical
Sociological	Warning
Scientific and Technical	
Transportation and Communications	

Any or all of these categories may be relevant to the private sector, depending upon the particular firm's product line and objectives in a given industry, market environment, and geographic area.

A nation's power or a firm's success results from a combination of factors, so intelligence producers and customers should examine potential adversaries and competitive situations from as many relevant viewpoints as possible. A competitor's economic resources, political alignments, the number, education and health of its people, and apparent objectives are all important in determining the ability of a country or a business to exert influence on others. The eight subject categories of intelligence are exhaustive, but they are not mutually exclusive. Although dividing intelligence into subject areas is useful for analyzing information and administering production, it should not become a rigid formula. Some intelligence services structure production into geographic subject areas when their responsibilities warrant a broader perspective than topical divisions would allow.[22]

---

[21] Ronald D. Garst, "Components of Intelligence," in *A Handbook of Intelligence Analysis*, ed. Ronald D. Garst, 2d ed. (Washington, DC: Defense Intelligence College, January 1989), 1; Central Intelligence Agency, *A Consumer's Guide to Intelligence* (Washington, DC: Public Affairs Staff, July 1995), 5-7.

[22] Garst, *Components of Intelligence*, 2,3.

Similarly, characterization of intelligence by intended use applies to both government and enterprise, and the categories again are exhaustive, but not mutually exclusive. The production of basic research intelligence yields structured summaries of topics such as geographic, demographic, and political studies, presented in handbooks, charts, maps, and the like. Current intelligence addresses day-to-day events to apprise decisionmakers of new developments and assess their significance. Estimative intelligence deals with what might be or what might happen; it may help policymakers fill in gaps between available facts, or assess the range and likelihood of possible outcomes in a threat or "opportunity" scenario. Operational support intelligence incorporates all types of intelligence by use, but is produced in a tailored, focused, and timely manner for planners and operators of the supported activity. Scientific and Technical intelligence typically comes to life in in-depth, focused assessments stemming from detailed physical or functional examination of objects, events, or processes, such as equipment manufacturing techniques.[23] Warning intelligence sounds an alarm, connoting urgency, and implies the potential need for policy action in response.

How government and business leaders define their needs for these types of intelligence affects the intelligence service's organization and operating procedures. Managers of this intricate process, whether in government or business, need to decide whether to make one intelligence unit responsible for all the component parts of the process or to create several specialized organizations for particular sub-processes. This question is explored briefly below, and more fully in Part VII.

Functional Organization of Intelligence

The national Intelligence Community comprises Executive Branch agencies that produce classified and unclassified studies on selected foreign developments as a prelude to decisions and actions by the president, military leaders, and other senior authorities. Some of this intelligence is developed from special sources to which few individuals have access except on a strictly controlled "need-to-know" basis.[24] The four categories of special intelligence are Human Resources (HUMINT), Signals (SIGINT), Imagery (IMINT) and Measurement and Signatures (MASINT). The four corresponding national authorities for these categories are the Central Intelligence Agency (CIA), the National Security Agency (NSA), the National Imagery and Mapping Agency (NIMA) and the Defense Intelligence Agency (DIA). DIA shares authority for HUMINT, being responsible for Department of Defense HUMINT management. Along with these four agencies, other members of the Intelligence Community use and produce intelligence by integrating all available and relevant collected information into reports tailored to the needs of individual customers.

Private sector organizations use open-source information to produce intelligence in a fashion similar to national authorities. By mimicking the government process of translating customer needs into production requirements, and particularly by performing rigorous analysis on gathered information, private organizations can produce assessments that aid their leaders in

---

[23] CIA, *Consumer's Guide*, 5-7.
[24] CIA, *Consumer's Guide*, vii.

planning and carrying out decisions to increase their competitiveness in the global economy. This primer will point out why private entities may desire to transfer into their domain some well-honed proficiencies developed in the national Intelligence Community. At the same time, the Intelligence Community self-examination conducted in these pages may allow government managers to reflect on any unique capabilities worthy of further development and protection.

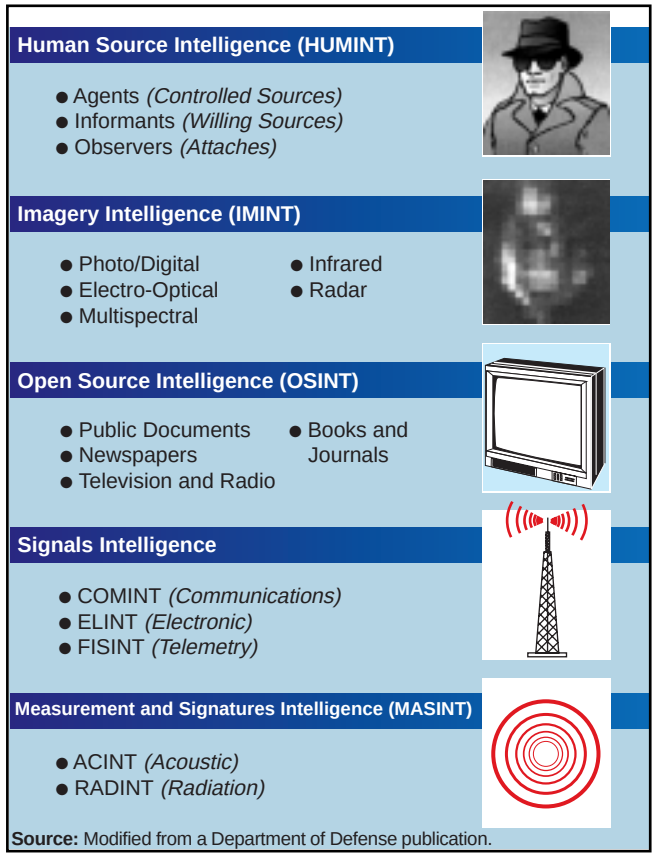

Figure 3: National Intelligence Production Resources.

PART II
CONVERTING CUSTOMER NEEDS INTO INTELLIGENCE REQUIREMENTS

> The articulation of the requirement is the most important part of the process, and it seldom is as simple as it might seem. There should be a dialogue concerning the requirement, rather than a simple assertion of need. Perhaps the customer knows precisely what is needed and what the product should look like. Perhaps... not. Interaction is required: discussion between ultimate user and principal producer. This is often difficult due to time, distance, and bureaucratic impediments, not to mention disparities of rank, personality, perspectives, and functions.[25]

Defining the Intelligence Problem

Customer demands, or "needs," particularly if they are complex and time-sensitive, require interpretation or analysis by the intelligence service before being expressed as intelligence requirements that drive the production process.[26] This dialog between intelligence producer and customer may begin with a simple set of questions, and if appropriate, progress to a more sophisticated analysis of the intelligence problem being addressed.

The "Five Ws" — *Who*, *What*, *When*, *Where*, and *Why* — are a good starting point for translating intelligence needs into requirements. A sixth related question, *How*, may also be considered. In both government and business, these questions form the basic framework for decisionmakers and intelligence practitioners to follow in formulating intelligence requirements and devising a strategy to satisfy them. Typically, government intelligence requirements are expressed in terms of foreign threats to national or international security. In business, requirements may be expressed in terms of the competitor's standing in the marketplace in comparison to one's own posture. Representative examples from each sector follow:

[25] Dearth, "National Intelligence," 17-18.
[26] Dearth, "National Intelligence," 18.

Table 2: Illustrative Definitions of Intelligence Problems and Customer Needs

Source: Author

A Government Scenario

The Intelligence Problem					
Who	***What***	***When***	***Where***	***Why***	***How***
A foreign president	Refusing to allow weapons sites to be inspected	Now; for several months	Country X	Unknown, possibly to hide illegal weapons	Barring access, destroying monitoring equipment
The Intelligence Need					
Who	***What***	***When***	***Where***	***Why***	***How***
U.S. President	Wants info on Country X President	Now, and update	White House	Determine power base and intent	All-source collection & analysis

A Business Scenario

The Intelligence Problem					
Who	***What***	***When***	***Where***	***Why***	***How***
Company X	Reorganizes production department	Sudden	Saturated market	Unknown	Unknown
The Intelligence Need					
Who	***What***	***When***	***Where***	***Why***	***How***
CEO of similar Company Y	Wants to know why and how Company X changed	ASAP	CEO's office	Determine if new structure gives advantage	Open source analysis; tailored, confidential report

Examination of these basic scenarios should inspire further development of the concept of determining customer needs in specific situations. The thoughtful researcher may propose, for example, ways to gather information on additional aspects of the problem (Who, What) and on customers (Who), as well as on the attendant motivations (Why) and strategies (How) of the target and the customer. Defining the intelligence problem in this manner paves the way for the next step in the intelligence process — the development of intelligence collection, analysis, and production *requirements*, explained later in this chapter.

Another, more complex model for defining intelligence scenarios employs the Taxonomy of Problem Types.[27] The table below illustrates the factors that customers and producers may take into account in articulating the nature of the intelligence problem and selecting a strategy for resolving it.

Table 3: Taxonomy of Problem Types

Source: Analysis course material, Joint Military Intelligence College, 1991

Characteristics	Problem Types				
	Simplistic	**Deterministic**	**Moderately Random**	**Severely Random**	**Indeterminate**
What is the question?	Obtain information	How much? How many	Identify and rank all outcomes	Identify outcomes in unbounded situation	Predict future events/ situations
Role of facts	Highest	High	Moderate	Low	Lowest
Role of judgment	Lowest	Low	Moderate	High	Highest
Analytical task	Find information	Find/create formula	Generate all outcomes	Define potential outcomes	Define futures factors
Analytical method	Search sources	Match data to formula	Decision theory; utility analysis	Role playing and gaming	Analyze models and scenarios
Analytical instrument	Matching	Mathematical formula	Influence diagram, utility, probability	Subjective evaluation of outcomes	Use of experts
Analytic output	Fact	Specific value or number	Weighted alternative outcomes	Plausible outcomes	Elaboration on expected future
Probability of error	Lowest	Very low	Dependent on data quality	High to very high	Highest
Follow-up task	None	None	Monitor for change	Repeated testing to determine true state	Exhaustive learning

[27] Morgan D. Jones, *The Thinker's Toolkit* (New York: Random House, 1995), 44-46, as elaborated by Thomas H. Murray, Sequoia Associates, Inc., Arlington, VA., in coursework at the Joint Military Intelligence College.

As with the "Five Ws," this model enables decisionmakers and analysts to assess their needs and capabilities in relation to a particular intelligence scenario. This ability to establish a baseline and set in motion a collection and production strategy is crucial to conducting a successful intelligence effort. Too often, both producers and customers waste valuable time and effort struggling to characterize for themselves a given situation, or perhaps worse, they hastily embark upon an action plan without determining its appropriateness to the problem. Employing a structured approach as outlined in the Taxonomy of Problem Types can help the players avoid these inefficiencies and take the first step toward generating clear intelligence requirements by defining both the intelligence problem and the requisite components to its solution. Following are example scenarios. The reader is encouraged to follow the scenarios down the columns of the taxonomy table, then generate new scenarios in similar fashion.

Intelligence Problem Definition

A Government Scenario

The Severely Random problem type is one frequently encountered by the military in planning an operational strategy. This is the realm of wargaming. The initial intelligence problem is to identify all possible outcomes in an unbounded situation, so that commanders can generate plans for every contingency. The role of valid data is relatively minor, while the role of judgment is great, as history and current statistics may shed little light on how the adversary will behave in a hypothetical situation, and the progress and outcome of an operation against that adversary cannot be predicted with absolute accuracy. Therefore, the analytical task is to define and prepare for all potential outcomes. The analytical method is role playing and wargaming: placing oneself mentally in the imagined situation, and experiencing it in advance, even to the point of acting it out in a realistic setting. After experiencing the various scenarios, the players subjectively evaluate the outcomes of the games, assessing which ones may be plausible or expected to occur in the real world. The probability of error in judgment here is inherently high, as no one can be certain that the future will occur exactly as events unfolded in the game. However, repeated exercises can help to establish a measure of confidence, for practice in living out these scenarios may enable the players to more quickly identify and execute desired behaviors, and avoid mistakes in a similar real situation.

A Business Scenario

The Indeterminate problem type is one facing the entrepreneur in the modern telecommunications market. Predicting the future for a given proposed new technology or product is an extremely imprecise task fraught with potentially dire, or rewarding, consequences. The role of valid data is extremely minor here, whereas analytical judgments about the buying public's future — and changing — needs and desires are crucial. Defining the key factors influencing the future market is the analytical task, to be approached via the analytical method of setting up models and scenarios: the if/then/else process. Experts in the proposed technology or market are then employed to analyze these possibilities. Their output is a synthesized assessment of how the future will look under various conditions with regard to the

proposed new product. The probability of error in judgment is extremely high, as the decision is based entirely on mental models rather than experience; after all, neither the new product nor the future environment exists yet. Continual reassessment of the changing factors influencing the future can help the analysts adjust their conclusions and better advise decisionmakers on whether, and how, to proceed with the new product.

Generating Intelligence Requirements

Once they have agreed upon the nature of the intelligence problem at hand, the intelligence service and the customer together can next generate intelligence *requirements* to drive the production process. The intelligence requirement translates customer needs into an intelligence action plan. A good working relationship between the two parties at this stage will determine whether the intelligence produced in subsequent stages actually meets customer needs. However, the differing perspectives that each side brings to the negotiation process can make cooperation between them a difficult feat.[28]

Customers want intelligence to guide them clearly in making policy and operational decisions. They may have little understanding of the intelligence process, and little patience for the subjectivity and conditionality of intelligence judgments. For customers, intelligence can be just one of many influences on their decisionmaking, and may be given little weight in comparison to other, more readily digested, familiar, or policy-oriented inputs. However, intelligence is neither designed nor equipped to meet these customer expectations.[29]

As a discipline, intelligence seeks to remain an independent, objective advisor to the decisionmaker. The realm of intelligence is that of "fact," considered judgment, and probability, but not prescription. It does not tell the customer what to do to meet an agenda, but rather, identifies the factors at play, and how various actions may affect outcomes. Intelligence tends to be packaged in standard formats and, because of its methodical approach, may not be delivered within the user's ideal timeframe. For all these reasons, the customer may not see intelligence as a useful service.[30]

Yet, somehow the intelligence producer and customer must reconcile their differing perspectives in order to agree on intelligence requirements and make the production process work. Understanding each other's views on intelligence is the first step toward improving the relationship between them. The next step is communication. Free interaction among the players will foster agreement on intelligence priorities and result in products that decisionmakers recognize as meaningful to their agendas, yet balanced by rigorous analysis.[31] In addition, as discussed below, customer feedback on production quality will lead to better definition of future intelligence problems and requirements.

Types of Intelligence Requirements

Having thus developed an understanding of customer needs, the intelligence service may proactively and continuously generate intelligence collection and production requirements to maintain customer-focused operations. Examples of such internally generated specifications include analyst-driven, events-driven, and scheduled requirements. The table below briefly describes them.[32]

Table 4: Types of Producer-Generated Intelligence Collection and Production Requirements

Source: Hulnick

Analyst-driven	Based on knowledge of customer and issues
Events-driven	In response to time-sensitive relevant events
Scheduled	Periodic activities to document and update target status

Further distinctions among intelligence requirements include timeliness and scope, or level, of intended use. Timeliness of requirements is established to meet standing (long-term) and *ad hoc* (short-term) needs. When the customer and intelligence service agree to define certain topics as long-term intelligence issues, they generate a standing requirement to ensure that a regular production effort can, and will, be maintained against that target. The customer will initiate an *ad hoc* requirement upon realizing a sudden short-term need for a specific type of intelligence, and will specify the target of interest, the coverage timeframe, and the type of output desired.

The scope or level of intended use of the intelligence may be characterized as strategic or tactical. Strategic intelligence is geared to a policymaker dealing with big-picture issues affecting the mission and future of an organization: the U.S. President, corporate executives, high-level diplomats, or military commanders of major commands or fleets. Tactical intelligence serves players and decisionmakers "on the ground" engaged in current operations: trade negotiators, marketing and sales representatives, deployed military units, or product developers.

Table 5: Types of Customer-Defined Intelligence Requirements

Source: Author

Timeliness	Short-term *(ad hoc)*	Long-term (standing)
Scope	Broad (strategic)	Narrow (tactical)

[32] Adapted from Arthur S. Hulnick, "Managing Intelligence Analysis: Strategies for Playing the End Game," *International Journal of Intelligence and CounterIntelligence* 2, No. 3 (Fall 1988): 327.

Ensuring that Requirements Meet Customer Needs

Even when they follow this method of formulating intelligence requirements together, decisionmakers and their intelligence units in the public and private sectors may still have an incomplete grasp of how to define their needs and capabilities — until they have evaluated the resultant products. Thus, customer feedback, production planning and tasking, as well as any internal product evaluation, all become part of the process of defining needs and creating intelligence requirements. However, when intelligence producers and users are not in nearly direct, daily contact, this process can consume a good deal of time. This is why the national Intelligence Community is experimenting with compressing both the accustomed time and spatial dimensions of the intelligence process through remote electronic collaboration and production methods.[33]

Whether in business or government, six fundamental values or attributes underlie the core principles from which all the essential intelligence functions are derived. The corollary is that intelligence customers' needs may be defined and engaged by intelligence professionals using these same values. Table 6 offers a brief explanation of how both intelligence customers and producers may use these values to evaluate how well they have translated needs into requirements that will result in useful products.[34]

Interpretation of these values turns a customer's need into a collection and production requirement that the intelligence service understands in the context of its own functions. However, illustrating the complexity of the intelligence process, once this is done, the next step is not necessarily collection.

Rather, the next stage is analysis. Perhaps the requirement is simply and readily answered — by an existing product, by ready extrapolation from files or data bases, or by a simple phone call or short desk note based on an analyst's or manager's knowledge. On the other hand, the requirement might necessitate laborious effort — extrapolation, collation, analysis, integration, and production — but still the product can be constructed and sent directly to the requester. Case closed; next problem.... Preliminary analysis might well show, however, that while much data exists, because the issue at hand is not a new one, gaps in information must be filled... Obviously, this calls for collection. This brings up an essential point: consumers do not drive collection *per se*; analysts do — or should.[35] Part III explores this next step in the intelligence process.

---

[33] The U.S. military has pioneered the concept of an electronic intelligence operating environment that transcends organizational boundaries. Congress has recommended that the IC adopt this *Joint Intelligence Virtual Architecture* model to take advantage of technological developments, reduce bureaucratic barriers, and thereby provide policymakers with timely, objective, and useful intelligence. See U.S. Congress Staff Study, House Permanent Select Committee on Intelligence, *IC21: The Intelligence Community in the 21st Century,* (April 1996): Section III, "Intelligence Requirements Process."

[34] The six values are adapted by Brei from an earlier version of U.S. Department of Defense, Joint Chiefs of Staff, Joint Pub 2-0, *Joint Doctrine for Intelligence Support to Operations* (Washington, DC: GPO, 5 May 1995), IV-15.

[35] Dearth, "National Intelligence," 18-19.

Table 6: Intelligence Values

Source: Brei

Accuracy: All sources and data must be evaluated for the possibility of technical error, misperception, and hostile efforts to mislead.
Objectivity: All judgments must be evaluated for the possibility of deliberate distortions and manipulations due to self-interest.
Usability: All intelligence communications must be in a form that facilitates ready comprehension and immediate application. Intelligence products must be compatible with a customer's capabilities for receiving, manipulating, protecting, and storing the product.
Relevance: Information must be selected and organized for its applicability to a customer's requirements, with potential consequences and significance of the information made explicit to the customer's circumstances.
Readiness: Intelligence systems must be responsive to the existing and contingent intelligence requirements of customers at all levels of command.
Timeliness: Intelligence must be delivered while the content is still actionable under the customer's circumstances.

PART III
COLLECTION

The collection function rests on research — on matching validated intelligence objectives to available sources of information, with the results to be transformed into usable intelligence. Just as within needs-definition, analysis is an integral function of collection.

Collection Requirements

The collection *requirement* specifies exactly how the intelligence service will go about acquiring the intelligence information the customer needs. Any one, or any of several, players in the intelligence system may be involved in formulating collection requirements: the intelligence analyst, a dedicated staff officer, or a specialized collection unit.

In large intelligence services, collection requirements may be managed by a group of specialists acting as liaisons between customers and collectors (people who actually obtain the needed information, either directly or by use of technical means). Within that requirements staff, individual requirements officers may be dedicated to a particular set of customers, a type of collection resource, or a specific intelligence issue. This use of collection requirements officers is prevalent in the government. Smaller services, especially in the private sector, may assign collection requirements management to one person or team within a multidisciplinary intelligence unit that serves a particular customer or that is arrayed against a particular topic area.

Regardless of how it is organized, the requirements management function entails much more than simple administrative duties. It requires analytic skill to evaluate how well the customer has expressed the intelligence need; whether, how and when the intelligence unit is able to obtain the required information through its available collection sources; and in what form to deliver the collected information to the intelligence analyst.

Collection Planning and Operations

One method for selecting a collection strategy is to first prepare a list of expected target evidence. The collection requirements officer and the intelligence analyst for the target may collaborate in identifying the most revealing evidence of target activity, which may include physical features of terrain or objects, human behavior, or natural and man-made phenomena. The issue that can be resolved through this analysis is “What am I looking for, and how will I know it if I see it”?

Successful analysis of expected target evidence in light of the customer’s needs can determine what collection source and method will permit detection and capture of that evidence. Increasingly sophisticated identification of evidence types may reveal what collectible data are essential for drawing key conclusions, and therefore should be given priority; whether the evidence is distinguishable from innocuous information; and whether the intelligence service has the skills, time, money and authorization to collect the data

needed to exploit a particular target. Furthermore, the collection must yield information in a format that is either usable in raw form by the intelligence analyst, or that can be converted practicably into usable form.

For example, in the case of the first business scenario presented in Part II, the CEO needs intelligence on why and how the similar, competitor company suddenly reorganized its production department. The collection requirement might specify that the intelligence unit give first priority to this new issue; it will focus on collecting information about the competitor's reorganization. A list of relevant evidence might include the following: changes in personnel assignments, changes in supply of production components, budget deficit or surplus, age of infrastructure, breakthroughs in research and development, and changes in the cultural or natural environment. To exploit this evidence, the intelligence service would thus need direct or indirect access to information on the company's employees, its previous production methods, its financial status, its physical plant, its overall functional structure and operations, and the consumer market. The collection unit would choose from among the sources listed in Table 7 below those most likely to provide timely access to this information in usable form.

Finally, upon defining the collection requirement and selecting a collection strategy, the intelligence unit should implement that strategy by tasking personnel and resources to exploit selected sources, perform the collection, re-format the results if necessary to make them usable in the next stages, and forward the information to the intelligence production unit. This aspect of the collection phase may be called collection operations management. As with requirements management, it is often done by specialists, particularly in the large intelligence service. In smaller operations, the same person or team may perform some or all of the collection-related functions.

The small, multidisciplinary intelligence unit may experience certain benefits and disadvantages in managing multiple phases of the intelligence process at the same time. In comparison to the large, compartmentalized service, the smaller unit will likely experience greater overall efficiency of operations and fewer bureaucratic barriers to customer service. The same few people may act as requirements officers, operations managers and intelligence analysts/producers, decreasing the likelihood of communication and scheduling problems among them. This approach may be less expensive in terms of infrastructure and logistics than a functionally divided operation. On the other hand, the financial and time investment in training each individual in every facet of the intelligence process may be substantial. Furthermore, careful selection and assignment of personnel who thrive in a multidisciplinary environment will be vital to the unit's success, to help ward off potential worker stress and overload. An additional pitfall that the small unit should strive to avoid is the tendency to be self-limiting: overreliance on the same customer contacts, collection sources and methods, analytic approaches, and production formulas can lead to stagnation and irrelevance. The small intelligence unit should be careful to invest in new initiatives that keep pace with changing times and customer needs.

Collection Sources

The range of sources available to all intelligence analysts, including those outside of government, is of course much broader than the set of restricted, special sources available only for government use. U.S. government collection of information for intelligence purposes is channelled through the recognized intelligence collection disciplines described in Part I. From a different perspective, four general categories serve to identify the types of information sources available to the intelligence analyst: people, objects, emanations, and records. Strictly speaking, the information offered by these sources may not be called intelligence if the information has not yet been converted into a value-added product. In the government or private sector, collection may be performed by the reporting analyst or by a specialist in one or more of the collection disciplines. The following table, derived from Clauser and Weir, illustrates the distinct attributes offered by the four sources of intelligence.[36]

Table 7: Categories of Intelligence Sources by Analytic Use

Source: Adapted from Clauser and Weir

Source	Related Collection Discipline(s) and Source Attributes	Analytic Use
People	HUMINT; subject-matter experts, professional researchers, information specialists, eyewitnesses or participants	Transfer of first-hand knowledge, referral to other sources
Objects	IMINT; physical characteristics of equipment, materials, or products, such as texture, shape, size, and distinctive markings	Basis for emotive but objective reporting on composition, condition, origin, or human purpose
Emanations	MASINT, SIGINT; detectable phenomena given off by natural or man-made objects; electromagnetic energy, heat, sound, footprints, fingerprints, and chemical and material residues	Scientific and technical analysis
Records	IMINT, SIGINT, symbolic (written and oral reports, numerical tabulations) or non-symbolic (images, electro-magnetic recordings of data)	Research, background information, translation, conversion to usable form

[36] Jerome K. Clauser and Sandra M. Weir, *Intelligence Research Methodology: An Introduction to Techniques and Procedures for Conducting Research in Defense Intelligence* (Washington, DC: Defense Intelligence School, 1975), 111-117.

The following table offers examples from government and business of each source type.

Table 8: Comparison of Illustrative Intelligence Sources from Government and Business

Source: Author

Source	Information Provided	Government	Business
People	Inadvertent or intentional revelation by a person in a casual encounter, official meeting, or informant relationship	A foreign diplomat	A fellow exhibitor at a trade show
Objects	Physical and functional characteristics of the item, discerned through physical or visual examination	Military equipment	Products or components
Emanations	Clues about the identity and activities of the originator	Intercepted communications	Trace chemicals in factory effluent
Records	Evidence of existence and characteristics of target entities	Imagery, telemetry, documents	Product literature

The collection phase of the intelligence process thus involves several steps: translation of the intelligence need into a collection requirement, definition of a collection strategy, selection of collection sources, and information collection. The resultant collected information must often undergo a further conversion before it can yield intelligence in the analysis stage. Processing of collected information into intelligence information is addressed in the following Part of this primer.

PART IV
PROCESSING COLLECTED INFORMATION

From Raw Data to Intelligence Information

No matter what the setting or type of collection, gathered information must be packaged meaningfully before it can be used in the production of intelligence. Processing methods will vary depending on the form of the collected information and its intended use, but they include everything done to make the results of collection efforts usable by intelligence producers. Typically, "processing" applies to the techniques used by government intelligence services to transform raw data from special-source technical collection into intelligence *information*.[37]

> While collectors collect "raw" information, certain [collection] disciplines involve a sort of *pre-analysis* in order to make the information "readable" to the average all-source analyst. For instance: imagery analysts "read-out" the basic information on the image; foreign language broadcasts must be literally translated by linguists and analyzed for linguistic "context"; electronic signals require sorting out to be intelligible to the uninitiated in that arcane art; agent reports also need literal translations and perhaps comments as to access, context, assumed or proven past veracity.[38]

In the private sector, some processing activities are analogous to those of the government. Interpreting and annotating open-source information for a business intelligence service may include: marking locations of interest on a map or photograph, "translating" press releases or technical reports, transcribing the words of a speaker from video or audiotape into text, or drafting a detailed commentary from a personal interview.

Another term for processing, *collation*, encompasses many of the different operations that must be performed on collected information or data before further analysis and intelligence production can occur. More than merely physically manipulating information, collation organizes the information into a usable form, adding meaning where it was not evident in the original. Collation includes gathering, arranging, and annotating related information; drawing tentative conclusions about the relationship of "facts" to each other and their significance; evaluating the accuracy and reliability of each item; grouping items into logical categories; critically examining the information source; and assessing the meaning and usefulness of the content for further analysis. Collation reveals information

---

[37] The Department of Defense defines intelligence information as "unprocessed data of every description which may be used in the production of intelligence." (Department of Defense, Joint Chiefs of Staff, Joint Pub 1-02, *Dictionary of Military and Associated Terms* (Washington, DC: 23 March 1994), 184.)

[38] Dearth, "National Intelligence," 19.

gaps, guides further collection and analysis, and provides a framework for selecting and organizing additional information.[39]

Examples of collation include filing documents, condensing information by categories or relationships, and employing electronic database programs to store, sort, and arrange large quantities of information or data in preconceived or self-generating patterns. Regardless of its form or setting, an effective collation method will have the following attributes:

1. Be impersonal. It should not depend on the memory of one analyst; another person knowledgeable in the subject should be able to carry out the operation.

2. Not become the "master" of the analyst or an end in itself.

3. Be free of bias in integrating the information.

4. Be receptive to new data without extensive alteration of the collating criterion.[40]

Evaluating and Selecting Evidence

To prepare collected information for further use, one must evaluate its relevance and value to the specific problem at hand. An examination of the information's *source* and *applicability* to the intelligence issue can determine whether that information will be further employed in the intelligence production process. Three aspects to consider in evaluating the relevance of information sources are reliability, proximity, and appropriateness.

Reliability of a source is determined through an evaluation of its past performance; if the source proved accurate in the past, then a reasonable estimate of its likely accuracy in a given case can be made. A human source's own testimony of reliability may also be taken into account; qualifiers such as "certain," "believe," and "guess" indicate how sure the source is of the information being conveyed. However, if the source is completely untested, then evaluation of the information must be done solely on its own merits, independent of its origin.[41]

Proximity refers to the source's closeness to the information. The direct observer or participant in an event may gather and present evidence directly, but in the absence of such firsthand information, the analyst must rely on sources with varying degrees of proximity to

---

[40] Mathams, 86.

[41] adapted from Gary Harris, "Evaluating Intelligence Evidence," in *A Handbook of Intelligence Analysis*, ed. Ronald D. Garst, 2d ed. (Washington, DC: Defense Intelligence College, January 1989), 34-35. For an in-depth treatment of evidence evaluation techniques and factors, see David A. Schum, *Evidence and Inference for the Intelligence Analyst*, Vols. I and II (Lanham, MD: University Press of America, 1987).

the situation. A primary source passes direct knowledge of an event on to the analyst. A secondary source provides information twice removed from the original event; one observer informs another, who then relays the account to the analyst. Such regression of source proximity may continue indefinitely, and naturally, the more numerous the steps between the information and the source, the greater the opportunity for error or distortion.[42]

Appropriateness of the source rests upon whether the source speaks from a position of authority on the specific issue in question. As no one person or institution is an expert on all matters, the source's individual capabilities and shortcomings affect the level of validity or reliability assigned to the information it provides regarding a given topic.[43]

The following examples illustrate the use of reliability, proximity, and appropriateness to evaluate a source.

> The mail clerk at 3rd Army Headquarters told me that, according to the 1st Armored Division Supply Officer, the Division is being deployed to Site Y in three days.

The reliability of the mail clerk as a source (questionable), his proximity to the information (secondary), and the appropriateness of the Supply Officer as a source on the fact of deployment (uncertain), make this information of little value to the intelligence production process.

> A major national newspaper published an interview with the CEO of Big Company, quoting the CEO's announcement of a merger the company had just secretly concluded with Large Company.

The reliability of a major national newspaper as a source (good), its proximity to the information (secondary), and the appropriateness of the CEO as the source of the merger announcement (high) make this information of high value to intelligence production.

Three aspects of the information itself have a bearing on its applicability to intelligence issues: plausibility, expectability, and support. *Plausibility* refers to whether the information is true under any circumstances or only under certain conditions, either known or possible. *Expectability* is assessed in the context of the analyst's prior knowledge of the subject. *Support* for information exists when another piece of evidence corroborates it — either the same information from a different source, or different information that points to the same conclusion.[44]

For example, a source contends that the President of Country X recently died, but the death is being kept secret from all but a few members of his regime. Although unusual, this information is plausible, and even has precedent in history. The scenario may meet the expectability criterion, if the country or this particular regime is known to be

---

[42] Harris, 35.
[43] adapted from Harris, 36.
[44] adapted from Harris, 36-38.

extremely secretive and paranoid about being vulnerable to hostile internal or external takeover movements. Support for this information may come from the same source providing details on the President's secret burial ceremony, or a different source, such as an actor who was hired to play the part of the President in a false Presidential address televised to the nation.

All these factors of source and content contribute to an initial assessment of the value of a particular piece of information to the intelligence production process. Those pieces that are judged to be useful may then undergo further scrutiny in light of customer needs, while items of questionable value may be rejected or set aside for further processing and comparison with other information. This initial selection of intelligence information sets the stage for intelligence analysis and production, as explained in the following Parts of the primer.

PART V
ANALYSIS

> Analysis is the breaking down of a large problem into a number of smaller problems and performing mental operations on the data in order to arrive at a conclusion or a generalization. It involves close examination of related items of information to determine the extent to which they confirm, supplement, or contradict each other and thus to establish probabilities and relationships.
>
> — *Mathams, 88.*

Analysis is not merely reorganizing data and information into a new format. At the very least, analysis should fully *describe* the phenomenon under study, accounting for as many relevant variables as possible. At the next higher level of analysis, a thorough *explanation* of the phenomenon is obtained, through interpreting the significance and effects of its elements on the whole. Ideally, analysis can reach successfully beyond the descriptive and explanatory levels to synthesis and effective persuasion, often referred to as *estimation*.

The *purpose* of intelligence analysis is to reveal to a specific decisionmaker the underlying significance of selected target information. Frequently intelligence analysis involves estimating the likelihood of one possible outcome, given the many possibilities in a particular scenario. This function is not to be confused with prediction, as no one can honestly be credited with predicting the future. However, intelligence analysis does appropriately involve forecasting, "which requires the explicit statement by the analyst of the degree of confidence held in a certain set of judgments, based upon a certain set of explicit facts or assumptions."[45] Different levels of analysis result in corresponding levels of conclusions that may be traced along an "Intelligence Food Chain."[46] This concept, illustrated in the following table, is equally applicable in government and business intelligence.

Table 9: The Intelligence Food Chain

Source: adapted from Davis, Analytic Tradecraft

Facts	verified information related to an intelligence issue (for example: events, measured characteristics).
Findings	expert knowledge based on organized information that indicates, for example, what is increasing, decreasing, changing, taking on a pattern.
Forecasts	judgments based on facts and findings and defended by sound and clear argumentation.
Fortunetelling	inadequately explained and defended judgments.

[45] Dearth, "National Intelligence," 25.

[46] Adapted from Jack Davis, *Intelligence Changes in Analytic Tradecraft in CIA's Directorate of Intelligence*, (Washington, DC: CIA Directorate of Intelligence, April 1995), 6.

Intelligence analysts may use this Food Chain model to measure their adherence to rigorous analytic thought — how far to go with their analytic judgments, and where to draw the line. The mnemonic "Four Fs Minus One" may serve as a reminder of how to apply this criterion. Whenever the intelligence information allows, and the customer's validated needs demand it, the intelligence analyst will extend the thought process as far along the Food Chain as possible, to the third "F" but not beyond to the fourth.

Types of Reasoning

Objectivity is the intelligence analyst's primary asset in creating intelligence that meets the Four Fs Minus One criterion. More than simply a conscientious attitude, objectivity is "a professional ethic that celebrates tough-mindedness and clarity in applying rules of evidence, inference, and judgment."[47] To produce intelligence objectively, the analyst must employ a process tailored to the nature of the problem. Four basic types of reasoning apply to intelligence analysis: induction, deduction, abduction and the scientific method.

Induction. The induction process is one of discovering relationships among the phenomena under study. For example, an analyst might discover from systematic examination of media reports that Country "X" had been issuing aggressive statements prior to formally announcing an arms agreement with Country "Y." Or an analyst may notice that a characteristic sequence of events always precedes Country "Z's" nuclear weapons tests.[48] In the words of Clauser and Weir:

> Induction is the intellectual process of drawing generalizations on the basis of observations or other evidence. Induction takes place when one learns from experience. For example, induction is the process by which a person learns to associate the color red with heat and heat with pain, and to generalize these associations to new situations.
>
> Induction occurs when one is able to postulate causal relationships. Intelligence estimates are largely the result of inductive processes, and, of course, induction takes place in the formulation of every hypothesis. Unlike other types of intellectual activities such as deductive logic and mathematics, there are no established rules for induction.[49]

Deduction. "Deduction is the process of reasoning from general rules to particular cases. Deduction may also involve drawing out or analyzing premises to form a conclusion."[50] In the case of Country "Z" above, the analyst noted a pattern of events related to testing of nuclear weapons. Later, after noticing this series of events occurring in Country "Z," the analyst may conclude that another nuclear weapons test is about to take place in that coun-

---

[47] Davis, *Analytical Tradecraft,* 5.
[48] Clauser and Weir, 81.
[49] Clauser and Weir, 81.
[50] clauser and Weir, 81.

try. The first premise, that certain events were related to weapons testing, was derived inductively — from specific observations to a conclusion. The second premise, that another test was imminent, was derived deductively — from a generalization to a specific case.[51]

Deduction works best in closed systems such as mathematics, formal logic, or certain kinds of games in which all the rules are clearly spelled out. For example, the validity and truthfulness of the following conclusion is apparent to anyone with a knowledge of geometry: "This is a triangle, therefore the sum of the interior angles will equal 180 degrees." In closed systems, properly drawn deductive conclusions are always valid.[52]

However, intelligence analysis rarely deals with closed systems, so premises assumed to be true may in fact be false, and lead to false conclusions. For example, in the weapons testing case above, Country "Z" may have deliberately deceived potential observers by falsely staging activities similar to those usually taken before a real weapons test. A conclusion that observed activities signalled a real test would be false in this case. Thus, as human activities rarely involve closed systems, deduction must be used carefully in intelligence analysis.[53]

Readers interested in further study into the use of deductive logic in estimative intelligence may wish to read the work of Israeli intelligence analyst Isaac Ben-Israel on this subject.[54] At the Joint Military Intelligence College, one student, Navy Lieutenant Donald Carney, explored the application of deductive logic to intelligence collection and analysis decisions in estimating the disintegration of Yugoslavia. Carney showed that Ben-Israel's "critical method" of inquiry could be applied prospectively to the collection of information to refute specific hypotheses, allowing for an unusually definitive estimate of the likelihood of each outcome.[55]

Abduction. Abduction is the process of generating a novel hypothesis to explain given evidence that does not readily suggest a familiar explanation. This process differs from induction in that it adds to the set of hypotheses available to the analyst. In inductive reasoning, the hypothesized relationship among pieces of evidence is considered to be already existing, needing only to be perceived and articulated by the analyst. In abduction, the analyst creatively generates an hypothesis, then sets about examining whether the available evidence unequivocally leads to the new conclusion. The latter step, testing the evidence, is a deductive inference.[56]

[56] David A. Schum, *Evidence and Inference for the Intelligence Analyst*, Volume I (Lanham, MD: University Press of America, 1987): 20.

Abductive reasoning may also be called intuition, inspiration, or the "Ah-ha!" experience. It characterizes the analyst's occasional ability to come to a conclusion spontaneously, often without a sense of having consciously taken definable steps to get there. While the abduction process may not be easily defined or taught, it may be encouraged by providing analysts with a wide array of research material and experiences, and by supporting the expenditure of time and energy on creative thinking.[57]

Examples of abductive reasoning in intelligence analysis include situations in which the analyst has a nagging suspicion that something of intelligence value has happened or is about to happen, but has no immediate explanation for this conclusion. The government intelligence analyst may conclude that an obscure rebel faction in a target country is about to stage a political coup, although no overt preparations for the takeover are evident. The business analyst may determine that a competitor company is on the brink of a dramatic shift from its traditional product line into a new market, even though its balance sheet and status in the industry are secure. In each case, the analyst, trusting this sense that the time is right for a significant event, will set out to gather and evaluate evidence in light of the new, improbable, yet tantalizing hypothesis.

Scientific Method. The scientific method combines deductive and inductive reasoning: Induction is used to develop the hypothesis, and deduction is used to test it. In science, the analyst obtains data through direct observation of the subject and formulates an hypothesis to explain conclusions suggested by the evidence. Experiments on the subject are devised and conducted to test the validity of the hypothesis. If the experimental results match the expected outcome, then the hypothesis is validated; if not, then the analyst must develop a new hypothesis and appropriate experimental methods.[58]

In intelligence analysis, the analyst typically does not have direct access to the observable subject, but gathers information indirectly. From these gathered data, the intelligence analyst may proceed with the scientific method by generating tentative explanations for a subject event or phenomenon. Next, each hypothesis is examined for plausibility and compared against newly acquired information, in a continual process toward reaching a conclusion. Often the intelligence analyst tests several hypotheses at the same time, whereas the scientist usually focuses on one at a time. Furthermore, intelligence analysts cannot usually experiment directly upon the subject matter as in science, but must generate fictional scenarios and rigorously test them through mental processes such as those suggested below.[59]

---

[57] The relationship of this type of reasoning to Eastern philosophy is addressed in LCDR William G. Schmidlin, USN, *Zen and the Art of Intelligence Analysis*, MSSI Thesis (Washington, DC: Joint Military Intelligence College, July 1993).

[58] Mathams, 91. A seminal contribution to understanding scientific method is Abraham Kaplan's *The Conduct of Inquiry* (San Francisco, CA: Chandler, 1964). The applicability of this method in social science, and therefore, in intelligence, is developed in Earl Babbie's *The Practice of Social Research* (Belmont, CA: Wadsworth Publishing Co, 1992).

[59] Mathams, 91.

Methods of Analysis

Opportunity Analysis. Opportunity analysis identifies for policy officials opportunities or vulnerabilities that the customer's organization can exploit to advance a policy, as well as dangers that could undermine a policy.[60] It identifies institutions, interest groups, and key leaders in a target country or organization that support the intelligence customer's objective; the means of enhancing supportive elements; challenges to positive elements (which could be diminished or eliminated); logistic, financial, and other vulnerabilities of adversaries; and activities that could be employed to rally resources and support to the objective.[61] Jack Davis notes that in the conduct of opportunity analysis,

> [T]he analyst should start with the assumption that every policy concern can be transformed into a legitimate intelligence concern. What follows from this is that analysts and their managers should learn to think like a policymaker in order to identify the issues on which they can provide utility, but they should always [behave like intelligence producers]. ... The first step in producing effective opportunity analysis is to redefine an intelligence issue in the policymaker's terms. This requires close attention to the policymaker's role as "action officer" - reflecting a preoccupation with getting things started or stopped among adversaries and allies.... It also requires that analysts recognize a policy official's propensity to take risk for gain....[P]olicymakers often see, say, a one-in-five chance of turning a situation around as a sound investment of [organizational] prestige and their professional energies....[A]nalysts have to search for appropriate ways to help the policymaker inch the odds upward - not by distorting their bottom line when required to make a predictive judgment, or by cheerleading, but by pointing to opportunities as well as obstacles. Indeed, on politically sensitive issues, analysts would be well advised to utilize a matrix that first lists and then assesses both the promising and discouraging signs they, as objective observers, see for... policy goals.... [P]roperly executed opportunity analysis stresses information and possibilities rather than [explicit] predictions.[62]

Linchpin Analysis. Linchpin analysis is one way of showing intelligence managers and policy officials alike that all the bases have been touched. Linchpin analysis, a colorful term for structured forecasting, is an *anchoring* tool that seeks to reduce the hazard of self-inflicted intelligence error as well as policymaker misinterpretation. At a minimum, linchpin tradecraft promotes rigor through a series of predrafting checkpoints, outlined below. Analysts can also use it to organize and evaluate their text when addressing issues

---

[60] Jack Davis, *The Challenge of Opportunity Analysis* (Washington, DC: Center for the Study of Intelligence, July 1992), v.

[61] Davis, *Opportunity Analysis*, 7.

[62] Davis, *Opportunity Analysis*, 12-13.

of high uncertainty. Reviewing managers can use — and have used — linchpin standards to ensure that the argument in such assessments is sound and clear.[63]

Table 10: Steps in Linchpin Analysis

Source: Davis, *Analytic Tradecraft*

1. Identify the main uncertain factors or key variables judged likely to drive the outcome of the issue, forcing systematic attention to the range of and relationships among factors at play.
2. Determine the *linchpin* premises or working assumptions about the drivers. This encourages testing of the key subordinate judgments that hold the estimative conclusion together.
3. Marshal findings and reasoning in defense of the linchpins, as the premises that warrant the conclusion are subject to debate as well as error.
4. Address the circumstances under which unexpected developments could occur. What *indicators* or patterns of development could emerge to signal that the linchpins were unreliable? And what *triggers* or dramatic internal and external events could reverse the expected momentum?

Analogy. Analogies depend on the real or presumed similarities between two things. For example, analysts might reason that because two aircraft have many features in common, they may have been designed to perform similar missions. The strength of any such analogy depends upon the strength of the connection between a given condition and a specified result. In addition, the analyst must consider the characteristics that are dissimilar between the phenomena under study. The dissimilarities may be so great that they render the few similarities irrelevant.

> One of the most widely used tools in intelligence analysis is the analogy. Analogies serve as the basis for most hypotheses, and rightly or wrongly, underlie many generalizations about what the other side will do and how they will go about doing it.[64]

Thus, drawing well-considered generalizations is the key to using analogy effectively. When postulating human behavior, the analyst may effectively use analogy by applying it to a specific person acting in a situation similar to one in which his actions are well documented: an election campaign or a treaty negotiation, for example. However, an assumption that a different individual running for the same office or negotiating a similar treaty would behave the same way as his predecessor may be erroneous. The key condition in this analogy is the personality of the individual, not the similar situations. This principle of appropriate comparison applies equally to government and business intelligence analysis.

---

[63] Davis, *Analytic Tradecraft*, 8-9.
[64] Clauser and Weir, 246-248.

> Analogies are used in many different kinds of intelligence analyses from military and political to industrial intelligence. For example, major U.S. auto makers purchase their competitors' models as soon as they appear in the showrooms. The new cars are taken to laboratories where they are completely and methodically disassembled. Reasoning by analogy, that is, assuming that it would cost one producer the same amount to produce or purchase the same components used by another, the major auto producers can estimate their competitors' per-unit production costs, any cost-saving measures taken, and how much profit is likely to be earned by the sale of a single unit.[65]

Customer Focus

As with the previous stages of the intelligence process, effective analysis depends upon a good working relationship between the intelligence customer and producer. A significant difference exists between the public and private sectors with regard to this customer-producer relationship. Government analysts typically benefit from close interaction with policymakers by virtue of their well understood institutional position. The same is not often true in the business world, where the intelligence analyst's role is not yet well institutionalized.

The government intelligence analyst is generally considered a legitimate and necessary policymaking resource, and even fairly junior employees may be accepted as national experts by virtue of the knowledge and analytic talent they offer to high level customers. Conversely, in the private sector, the intelligence analyst's corporate rank is generally orders of magnitude lower than that of a company vice-president or CEO. The individual analyst may have little access to the ultimate customer, and the intelligence service as a whole may receive little favor from a senior echelon that makes little distinction between so-called intelligence and the myriad of other decisionmaking inputs. When private sector practitioners apply validated methods of analysis geared to meet specific customer needs, they can win the same kind of customer appreciation and support as that enjoyed by government practitioners.

Statistical Tools

Additional decisionmaking tools derived from parametric or non-parametric statistical techniques, such as Bayesian analysis, are sometime used in intelligence. An exploration of them is beyond the scope of this study. Many of the statistically oriented tools continue to rely fundamentally on human judgment to assign values to variables, so that close attention to the types of reasoning and methods of analysis presented herein remain the fundamental analytical precondition to their use.[66]

---

[65] Clauser and Weir, 248-250.

[66] Editor's note: A former JMIC faculty member, Douglas E. Hunter, explores the intelligence applications of Bayesian Analysis in *Political/Military Applications of Bayesian Analysis: Methodological Issues* (Boulder, CO: Westview, 1984).

Analytic Mindset

Customer needs and collected information and data are not the only factors that influence the analytic process; the analyst brings his or her own unique thought patterns as well. This personal approach to problem-solving is "the distillation of the intelligence analyst's cumulative factual and conceptual knowledge into a framework for making estimative judgments on a complex subject."[67] Mindset helps intelligence analysts to put a situation into context, providing a frame of reference for examining the subject. Analysis could not take place if thinking were not bounded by such constructs. However, mindset can also lead analysts to apply certain viewpoints inappropriately or exclusively while neglecting other potentially enlightening perspectives on an issue. While no one can truly step outside his or her own mindset, becoming aware of potential analytic pitfalls can enable intelligence analysts to maximize the positive effects of mindset while minimizing the negatives.[68] Analysts can use the accompanying list of analytical pitfalls to determine which, if any, they may be applying in their work, and whether the relevant ones are accounted for in their analytic tasks.

Categories of Misperception and Bias[69]

Evoked-Set Reasoning: That information and concern which dominates one's thinking based on prior experience. One tends to uncritically relate new information to past or current dominant concerns.

Prematurely Formed Views: These spring from a desire for simplicity and stability, and lead to premature closure in the consideration of a problem.

Presumption that Support for One Hypothesis Disconfirms Others: Evidence that is consistent with one's preexisting beliefs is allowed to disconfirm other views. Rapid closure in the consideration of an issue is a problem.

Inappropriate Analogies: Perception that an event is analogous to past events, based on inadequate consideration of concepts or facts, or irrelevant criteria. Bias of "Representativeness."

Superficial Lessons From History: Uncritical analysis of concepts or events, superficial causality, over-generalization of obvious factors, inappropriate extrapolation from past success or failure.

Presumption of Unitary Action by Organizations: Perception that behavior of others is more planned, centralized, and coordinated than it really is. Dismisses accident and chaos. Ignores misperceptions of others. Fundamental attribution error, possibly caused by cultural bias.

---

[67] Jack Davis, "Combatting Mindset," *Studies in Intelligenc*e 35, no. 4 (Winter 1991): 13-18.
[68] Davis, "Combatting Mindset," 13-15.
[69] Excerpted from Dearth, "The Politics of Intelligence," 106-107.

Organizational Parochialism: Selective focus or rigid adherence to prior judgments based on organizational norms or loyalties. Can result from functional specialization. Group-think or stereotypical thinking.

Excessive Secrecy (Compartmentation): Over-narrow reliance on selected evidence. Based on concern for operational security. Narrows consideration of alternative views. Can result from or cause organizational parochialism.

Ethnocentrism: Projection of one's own culture, ideological beliefs, doctrine, or expectations on others. Exaggeration of the causal significance of one's own action. Can lead to mirror-imaging and wishful thinking. Parochialism.

Lack of Empathy: Undeveloped capacity to understand others' perception of their world, their conception of their role in that world, and their definition of their interests. Difference in cognitive contexts.

Mirror-Imaging: Perceiving others as one perceives oneself. Basis is ethnocentrism. Facilitated by closed systems and parochialism.

Ignorance: Lack of knowledge. Can result from prior-limited priorities or lack of curiosity, perhaps based on ethnocentrism, parochialism, denial of reality, rational-actor hypothesis (see next entry).

Rational-Actor Hypothesis: Assumption that others will act in a "rational" manner, based on one's own rational reference. Results from ethnocentrism, mirror-imaging, or ignorance.

Denial of Rationality: Attribution of irrationality to others who are perceived to act outside the bounds of one's own standards of behavior or decisionmaking. Opposite of rational-actor hypothesis. Can result from ignorance, mirror-imaging, parochialism, or ethnocentrism.

Proportionality Bias: Expectation that the adversary will expend efforts proportionate to the ends he seeks. Inference about the intentions of others from costs and consequences of actions they initiate.

Willful Disregard of New Evidence: Rejection of information that conflicts with already-held beliefs. Results from prior policy commitments, and/or excessive pursuit of consistency.

Image and Self-Image: Perception of what has been, is, will be, or should be (image as subset of belief system). Both inward-directed (self-image) and outward-directed (image). Both often influenced by self-absorption and ethnocentrism.

Defensive Avoidance: Refusal to perceive and understand extremely threatening stimuli. Need to avoid painful choices. Leads to wishful thinking.

Overconfidence in Subjective Estimates: Optimistic bias in assessment. Can result from premature or rapid closure of consideration, or ignorance.

Wishful Thinking (Pollyanna Complex): Hyper-credulity. Excessive optimism born of smugness and overconfidence.

Best-Case Analysis: Optimistic assessment based on cognitive predisposition and general beliefs of how others are likely to behave, or in support of personal or organizational interests or policy preferences.

Conservatism in Probability Estimation: In a desire to avoid risk, tendency to avoid estimating extremely high or extremely low probabilities. Routine thinking. Inclination to judge new phenomena in light of past experience, to miss essentially novel situational elements, or failure to reexamine established tenets. Tendency to seek confirmation of prior-held beliefs.

Worst-Case Analysis (Cassandra Complex): Excessive skepticism. Reflects pessimism and extreme caution, based on predilection (cognitive predisposition), adverse past experience, or on support of personal or organizational interests or policy preferences.

Because the biases and misperceptions outlined above can influence analysis, they may also affect the resultant analytic products. As explained in the following Part, analysis does not cease when intelligence production begins; indeed, the two are interdependent. The foregoing overview of analytic pitfalls should caution intelligence managers and analysts that intelligence products should remain as free as possible from such errors of omission and commission, yet still be tailored to the specific needs of customers. Consistently reminding intelligence producers of the dangers and benefits of mindset may help them avoid errors and polish their analytic skills. In addition, managers may conduct post-production evaluation of intelligence products, using the biases and misperceptions listed above to identify strengths and weaknesses in individual analysts' work, and to counsel them accordingly.

PART VI
PRODUCTION

Creating Intelligence

The previously-described steps of the intelligence process are necessary precursors to production, but it is only in this final step that functionality of the whole process is achieved. *Production* results in the creation of intelligence, that is, value-added actionable information tailored to a specific customer. In practical terms, production refers to the creation, in any medium, of either interim or *finished* briefings or reports for other analysts, or for decisionmakers or policy officials. As with elements of analysis developed in Part V, production principles described and explained here may apply to both government and private sector intelligence operations.

In government parlance, the term "finished" intelligence is reserved for products issued by analysts responsible for synthesizing all available sources of intelligence, resulting in a comprehensive assessment of an issue or situation, for use by senior analysts or decisionmakers. Creating finished intelligence for national and military customers is the role of CIA and DIA analysts, respectively. Analysts within an intelligence sub-discipline may also speak of a "finished" product from their point of view, meaning that intelligence from a single source, such as SIGINT, was interpreted as fully as possible in light of all other available intelligence from that source, plus any relevant published intelligence from other sources, and open source information. Analysts within the single-source intelligence agencies consider any information or intelligence not issued by their own organization to be "collateral."

Similar designations for finished intelligence products may apply in the business world. Particularly in large corporations with multidisciplinary intelligence units, or in business intelligence consulting firms, some production personnel may specialize in the creation of intelligence from a single source, while others specialize in finished reporting. For example, there may be specialists in library and on-line research, "HUMINT" experts who conduct interviews and attend conferences and trade shows, or scientists who perform experiments on products or materials. The reports generated by such personnel may be considered finished intelligence by their intended customers within subdivisions of the larger company. The marketing, product development, or public relations department of a corporation may consume single-source intelligence products designed to meet their individual needs. Such a large corporation may also have an intelligence synthesis unit that merges the reports from the specialized units into finished intelligence for use in strategic planning by senior decisionmakers. Similarly, in the intelligence consulting firm, each of the specialized production units may contribute their reports to a centralized finished intelligence unit which generates a synthesized product for the client.

Emphasizing the Customer's Bottom Line

The intelligence report or presentation must focus on the *results* of the analysis and make evident their significance through sound arguments geared to the customer's interests. In short, intelligence producers must BLUF their way through the presentation — that is, they must keep the "Bottom Line Up Front." This axiom applies not only to written expression, but also to oral briefings, or any other medium of expression used in the intelligence environment of government or business.

> It is often difficult for... intelligence [producers] to avoid the temptation to succumb to the Agatha Christie Syndrome. Like the great mystery writer, we want to keep our readers in suspense until we can deliver that "punch line." After we have worked hard on this analysis... we want the reader to know all the wonderful facts and analytical methods that have gone into our conclusions.... Most readers really will not care about all those bells and whistles that went into the analysis. ***They want the bottom line***, and that is what intelligence professionals are paid to deliver.[70]

Knowing the customer enables the producer to generate intelligence that highlights the bottom line. Some customers are "big picture" thinkers, seeking a general overview of the issue, and guidance on the implications for their own position and responsibilities. An appropriate intelligence product for such a customer will be clear, concise, conclusive, and free of jargon or distracting detail.[71] Conversely, some customers are detail-oriented, seeing themselves as the ultimate expert on the subject area. This type of customer needs highly detailed and specialized intelligence to supplement and amplify known information. The broad-brush approach to intelligence will not only miss the mark with this customer, but may actually be perceived as an insult, lessening the chances that future products by the offending producer will be accepted or used.[72] Producers should therefore tailor both the content and delivery of the intelligence to the customer. The following section provides guidelines for creating intelligence products that meet customer needs.[73]

Anatomy of an Intelligence Product

Whether it is produced within the government, or in the business setting, the basic nature of the intelligence product remains the same. The analyst creates a product to document ongoing research, give the customer an update on a current issue or situation, or

[73] The Central Intelligence Agency has published an unclassified collection of essays on techniques for producing finished national security intelligence. The purpose of the collection is to document best practices, and to reach out to academia and the public. Its title emphasizes the instrumentality of analysis to production. See Central Intelligence Agency, *A Compendium of Analytic Tradecraft Notes*, (Washington, DC, Directorate of Intelligence: February 1997).

provide an estimate of expected target activity. In general terms, the product's function is to cover one or more subject areas, or to be used by the customer for a particular application. Along with these aspects, additional dimensions of the intelligence product are summarized in the table below. They are more fully described in the following paragraphs.

Table 11: Dimensions of an Intelligence Product

Source: Author

Dimension Category	Dimension	Examples
Content	Subject	Biographical, economic, geographic, military, political, science and technology, sociology, transportation and communications
	Intended Use	Research, current, estimative, operational, science and technology, warning
Features	Timeliness	Short-/long-term, opportune, routine/priority
	Periodicity	Ad hoc/scheduled; analyst/customer-initiated
	Scope	Narrow/broad; detailed/summary; basic/exhaustive
Packaging	Medium	Hard/softcopy, written/oral, video
	Format	Formal/informal, textual/graphical
Customer	Relationship to producer	Intended/incidental recipient; internal/external; novice/expert
	Distribution method	Internal/external; direct/indirect; focused/broad

Content

Determination of product content is done in close cooperation with the customer, sometimes at the initiative of one or the other, often in a cycle of give-and-take of ideas. Formal intelligence requirements, agreed upon by both producer and customer in advance, do drive the production process, but the converse is also true. The intelligence unit's own self-concept and procedures influence its choice of which topics to cover, and which aspects to emphasize. As a result, the customer comes to expect a certain type of product from that unit, and adjusts requirement statements accordingly. In addition, the intelligence process may bring to light aspects of the target that neither the producer nor customer anticipated. When the parties involved have a close working relationship, either

one may receive inspiration from interim products, and take the lead in pursuing new ways to exploit the target.[74]

Often, this dialogue centers around the pursuit of new sources associated with known lucrative sources. Examples from government include HUMINT targeting of persons identified in SIGINT as having access to foreign leaders, and SIGINT targeting of communications equipment revealed in IMINT of a foreign military installation. Parallel business examples might include intelligence personnel following leads to new sources revealed in original research or a published report: A pharmaceutical industry analyst who reads a business intelligence report about current breast cancer treatments may then investigate how to access human and documentary sources mentioned in the report, for further information on new drug therapy options for the disease.

The basic orientation of the intelligence product toward a particular subject or application is also determined by the producer-customer relationship. Frequently, the intelligence service will organize the production process and its output to mirror the customer organization. Government production by the single-source intelligence agencies is largely organized geographically or topically, to meet the needs of all-source country, region, or topic analysts in the finished-intelligence producing agencies, such as DIA or the National Counterintelligence Center. In the private sector, some intelligence consultant firms are specializing in one subject area, and gearing all production to one customer set, such as the petroleum industry.

In terms of intended use by the customer, both business and government producers may generate intelligence to be applied in the current, estimative, operational, research, science and technology, or warning context. Serendipity plays a role here, because the collected and analyzed information may meet any or all of these criteria. A good example is warning intelligence. Military and political analysts are always alert for target indications that an emergency, such as outbreak of war, or a political coup, is imminent. Standing procedures dictate that routine operations switch to warning mode in this case, so that time-sensitive intelligence on the situation can be issued to all relevant customers. Business intelligence analysts may also find themselves in the warning role unexpectedly, when they make discoveries that have significant time-sensitive implications for customer decisions and actions.

Features

Three key features of the intelligence product are timeliness, scope, and periodicity. Timeliness includes not only the amount of time required to deliver the product, but also the usefulness of the product to the customer at a given moment. Scope involves the level of detail or comprehensiveness of the material contained in the product. Periodicity describes the schedule of product initiation and generation.

---

[74] Turner, 314-320.

In intelligence production, the adage "timing is everything" is particularly apt. When a customer requests specific support, and when actionable information is discovered through collection and analysis, the resultant intelligence product is irrelevant unless the customer receives it in time to take action — by adapting to or influencing the target entity. Timeliness therefore encompasses the short-term or long-term duration of the production process, and the degree to which the intelligence itself proves opportune for the customer. In addition, the relative priority of the intelligence contained in the product affects the timeliness calculus. For example, a business intelligence analyst conducting research for a consumer electronics corporation may produce short-term routine reports as new information becomes available. A long-term routine summary report may be the final output from this project. However, a short-term priority report may result at any time, if time-sensitive information on competitor capabilities or intentions comes to light.

The scope of an intelligence product describes both the amount of material it contains and the depth of coverage it provides on the topic. Its focus may be narrow or broad, and the content may be detailed or in summary form. The level of coverage may be basic or exhaustive. All of these aspects are determined by the customer's needs, and by the amount and extent of the source material available.

> The amount of detail distributed will depend on the circumstances and the requirements of the user. Time constraints often will determine how much detail is given. There may be such a wealth of detail on a particular subject that an analyst might spend a month or more making a detailed analysis, but the urgency of the need for the intelligence may be such as to make a brief survey, produced in two days, much more valuable. It is important to remember that many users of intelligence have neither the time nor the patience to read through a voluminous study, however excellent it may be, and would much prefer to have the essential elements of the analysis set down in a few succinct paragraphs. Some users, however, do require detail, and when that is the case it should be provided in a usable form.[75]

Periodicity is also linked to validated customer requirements. Intelligence products correspond to requirements that specify responsiveness criteria, thus production may occur on an *ad hoc* basis or on a schedule. Analysts may proactively generate products to meet known needs of specific customers, or they may respond to spontaneous customer requests for tailored intelligence. Furthermore, "analysts, as experts in their fields, are expected to initiate studies that address questions yet unformulated by [customers]."[76] By selecting from available source material, and determining when to issue an intelligence product, analysts have the potential to influence how their customers use intelligence to make policy decisions.[77] In the government, topic experts may become close advisors to National Intelligence Officers or directly to senior policymakers. In

[75] Mathams, 92.
[76] Turner, 319.
[77] Turner, 320.

the business world, a sharp intelligence analyst might be responsible for a dramatic change in a retail company's focus, by identifying emerging consumer trends and sensitizing management for the need to reorient the company. To effect this change, the company would become dependent on intelligence about competitors in the same industry. For example, an analyst's assessment of consumer interest in buying natural pet foods might stimulate requirements for further studies, and might lead a manufacturer to change its products to meet consumer demand, before another company captures that market.

Packaging

Government intelligence products are typically packaged as highly structured written and oral presentations, including electrical messages, hardcopy reports, and briefings.[78] Many organizations also generate video intelligence products, especially in the form of live daily "newscasts," or canned documentary presentations. However, the production landscape is being transformed by technology, and today, a wide range of options is available to both business and government. Modern telecommunications and software make possible a whole new world of intelligence production, in which all the players, including customers, are in constant interaction. The Department of Defense, for example, has devised the Joint Intelligence Virtual Architecture (JIVA) concept to accelerate and streamline the entire intelligence process. Under JIVA, intelligence personnel will use advanced communication and analysis tools to electronically collaborate with each other and their customers, resulting in improved timeliness and customization of Defense intelligence products.[79] Part of the JIVA concept is the use of on-line product modules that can stand alone as finished intelligence, or be synergistically combined with other modules for use by interim or ultimate customers.[80] Similar collaborative production techniques may be successful in large business intelligence units with geographically dispersed personnel and customers. However, the benefits offered by modern intelligence practices such as JIVA also present significant challenges, including the financial and political investment in new infrastructure, and the legal implications of the required cooperation between the government and technology firms.[81]

The format of the intelligence product, regardless of the medium used to convey it, affects how well it is received by the customer. Even in a multimedia presentation, the personal touch can make a positive difference. Therefore, the degree of formality, and the mix of textual and graphical material should match the customer's preferences. Some cus-

tomers want formal briefings, while others enjoy conversational give and take; some want a scheduled meeting, others want the analyst to be available at any time for impromptu consultation. Often, verbally oriented customers request one-on-one exchanges during official travel in automobiles or in airplanes. Conversely, the visually oriented customer may prefer video clips, graphs, charts, and photographs, accompanied by brief amplifying text. Many customers prefer written analyses, often in the form of concise executive summaries or point papers; some will ask for an in-depth study after consuming the initial or periodic assessment. However, producers should be aware of the potential pitfalls of relying on the executive summary to reach key customers. If the product does not appeal to the executive's staff members who read it first, it may never reach the intended recipient.[82]

Customer

In addition to understanding the customer's intelligence requirements, the producer may benefit from an awareness of the relationship between the customer organization and the intelligence service itself. Status issues between the two parties may influence the tone of the intelligence product. Aspects of the producer-customer relationship include whether the recipient is the intended or incidental customer, whether the customer is internal or external to the intelligence service, and whether the parties differ in their level of subject matter knowledge.

The intelligence producer selects the product content and format to suit a specific individual or customer set. However, the producer should beware of selecting material or phraseology that is too esoteric or personal for a potential wide audience. Intelligence products are official publications that become official records for use by all authorized personnel within the producer and customer organizations. They should focus on the primary customer's needs, yet address the interests of other legitimate players. Sometimes, when the producer is struggling with how to meet the needs of both internal and external customers, the solution is to create two different types of products, one for each type of customer. Internal products contain details about the sources and methods used to generate the intelligence, while external products emphasize actionable target information. Similarly, the producer adjusts the product content and tone to the customer's level of expertise. For example, a SIGINT producer may issue a highly technical and detailed product for fellow SIGINT service members, but for intelligence producers in a different agency, a less technical but still producer-oriented product may be appropriate. Similarly, the business intelligence producer within a marketing department may generate a highly specialized report for the head of the department, but may issue an executive summary for the company president.

Selection of the distribution method for the product is also closely tied to the relationship between producer and customer. The ability to deliver specific types of products to internal and external customers depends upon available infrastructure and

---

[82] Loch K. Johnson, *America's Secret Power, The CIA in a Democratic Society,* (New York: Oxford University Press, 1989): 98.

resources (telecommunications lines, transportation, media equipment). Politics affect whether intelligence can be delivered by the individual analyst directly to the customer, or only through a chain of command. Finally, the number of designated recipients is often determined by the sensitivity of the intelligence issue covered in the product. If the intelligence is highly sensitive, such as a report on threats to the president's life, then only the few involved persons (the president and a few key security personnel) will receive the report. A routine report may be broadly distributed to a large customer set. Thus, the choice of distribution method is more a marketing decision than a mechanical exercise.[83] Successful delivery of a truly useful intelligence product to a receptive customer is the result of communication and cooperation among all the players.

Customer Feedback and Production Evaluation

The production phase of the intelligence process does not end with delivering the product to the customer. Rather, it continues in the same manner in which it began: with dialogue between producer and customer.

> If the product is really to be useful for policy-making and command, dissemination involves feedback, which is part of the marketing function.... Ideally, the "marketer" who delivers the product is the same individual who accepts and helps to refine the initial requirement.[84]

Intelligence producers need feedback from end-users. If producers do not learn what is useful and not useful to customers, they cannot create genuine intelligence. Internal review procedures that focus on the format and style of intelligence products are not sufficient for producers to judge their performance; they must hear from customers on the intelligence value of their work. Then producers can modify their practices to further develop those activities that served the customer well, and improve or eliminate those that did not.

Feedback procedures between producers and customers should include key questions, such as: Is the product usable? Is it timely? Was it in fact used? Did the product meet expectations? If not, why not? What next? The answers to these questions will lead to refined production, greater use of intelligence by decisionmakers, and further feedback sessions. Thus, production of intelligence actually generates more requirements in this iterative process.[85] Producers and managers may use the framework developed by Brei and summarized below as an initial checklist for evaluating their own work, and as a basis for formal customer surveys to obtain constructive feedback.

Producers also need performance feedback from their own managers. Useful aspects of such an internal evaluation may include whether the output met the conditions set down by customers and producers in formal intelligence requirements, whether the intel-

---

[83] Johnson, 97.
[84] Dearth, "National Intelligence," 20.
[85] Dearth, "National Intelligence," 20.

ligence was indeed used by customers, and whether the product resulted from a high standard of analytic quality.[86] To establish a formal internal review process for monitoring the quality of analysis in intelligence products, managers could select experienced analysts to serve on a rotating basis as "mindset coaches" — reviewing assessments for issues of mindset, uncertainty, and policy utility, or consider pairing with another production division to swap personnel for this activity. As a rule, the less the critical reader knows about the substance of the paper the more he or she will concentrate on the quality of the argumentation. A reward for the best "mindset coaches" would be to make them branch chiefs.[87]

Table 12: A Framework for Intelligence Product Evaluation and Customer Feedback

Source: adapted from Brei

Accuracy: Were all sources and data free of technical error, misperception, and hostile efforts to mislead?

Objectivity: Were all judgments free of deliberate distortions and manipulations due to self-interest?

Usability: Was all production issued in a form that facilitated ready comprehension and immediate application? Were products compatible with the customer's capabilities for receiving, manipulating, protecting, and storing the product?

Relevance: Was information selected and organized for its applicability to a customer's requirements, with potential consequences and significance of the information made explicit to the customer's circumstances?

Readiness: Are intelligence systems responsive to the existing and contingent intelligence requirements of customers at all levels of command?

Timeliness: Was intelligence delivered while the content was still actionable under the customer's circumstances?

Management's role extends beyond fostering quality production, to bearing responsibility for organizing and administering the complete intelligence process. Managers make key decisions that mirror the intelligence process and make production possible. In conjunction with customers, managers determine what customer set the intelligence unit will serve; what sources it will exploit; what types of intelligence it will produce; and what methods of collection, processing, analysis, production, customer feedback, and self-evaluation it will use. The following Part of this primer explores best practices in managing the intelligence process.

[86] Arthur S. Hulnick, "Managing Intelligence Analysis," 338.
[87] Davis, "Mindset," 17.

PART VII
MANAGING THE INTELLIGENCE PROCESS

The Role of Management

> Another discipline integral to the intelligence profession — but worthy of special consideration in this context — is that of management. The effective administration and direction of intelligence activities can be regarded as the epitome of intelligence professionalism. Just as an untutored civilian cannot be expected competently to command [a military unit], so an untrained or inexperienced layperson cannot be expected effectively to direct [an intelligence operation]. But mastery of professional intelligence skills does not, in itself, ensure that a person is able to direct intelligence functions competently; expertise in administrative techniques and behavioral skills is also essential to managerial effectiveness. Some facility in these areas can be acquired through experience, but a professional level of competence requires familiarity with the principles and theories of management, and leadership.[88]

Moreover, supervisors and managers have a particular responsibility for ensuring the professional development of their subordinates. When all the members of the intelligence unit are competent, then the effectiveness of the group increases. Enabling subordinates also frees managers to thoroughly plan and administer the intelligence operation, instead of redoing the work of production personnel. Meanwhile, managers may continue to broaden their own knowledge of the intelligence process and its customer-service mission.[89]

Organizing the Intelligence Service

In the national Intelligence Community, federal laws form the basis for a centrally coordinated but functionally organized system. The Director of Central Intelligence (DCI) leads the community with the aid of the National Intelligence Council (NIC). Members of the NIC come from all the intelligence agencies plus academia and the private sector. The

[88] George Allen, "The Professionalization of Intelligence," in Dearth and Goodden, 1995, 37. Informed debate on the realities of analysts' and managers' intelligence responsibilities toward customers is ongoing in the *International Journal of Intelligence and CounterIntelligence.* Examples of this literature are: Michael A. Turner, "Setting Analytical Priorities in U.S. Intelligence," 9, no. 3 (Fall 1996): 313-327; H. Bradford Westerfield, "Inside Ivory Bunkers: CIA Analysts Resist Managers' "Pandering" Part I, 9, no. 4 (Winter 1996/97): 407-424; and H. Bradford Westerfield, "Inside Ivory Bunkers: CIA Analysts Resist Managers' "Pandering" Part II, 10, no. 1 (Spring 1997): 19-54.

[89] Russell G. Swenson, *An Office Manager's Guide to Intelligence Readiness,* Occasional Paper Number Three (Washington, DC: JMIC, December 1996), 3-5.

NIC manages the national Intelligence Needs Process and supervises the production of National Intelligence Estimates for senior policymakers. Other senior bodies advise or assist the DCI in matters of policy, resource management, performance review, coordination of elements, customer relations, and intra-community relations.[90] Four topical intelligence centers staffed by multiple agencies coordinate intelligence production for policymakers in the key areas of Counterterrorism, Counterintelligence, Counternarcotics, and Nonproliferation.[91] Crisis situations may spark the formation of a temporary special task force, integrating intelligence functions that are usually separate. Although the national Intelligence Community is centrally coordinated, each member organization develops some self-determined policies and procedures, and engages in competitive analysis with respect to the other organizations.

The unifying principle across government intelligence missions is the basic charter to monitor and manage threats to national interests and to the intelligence service itself. In both the national Intelligence Community and the business community, managers may make a distinction between self-protective intelligence activities and competitive intelligence activities. Self-protection involves gathering and analyzing data about threats to public, personal, or multinational mission members' security, whereas competitive activities involve gathering and analyzing data about adversary organizations or countries. In business, the two functions are sometimes undertaken by entirely different companies or groups within the same company.[92] Government subordinates both functions within the intelligence infrastructure.

Table 13: Three Contexts for Government and Business Intelligence Tasks

Source: Author and Editor

Contexts:	**Individual**	**Corporate**	**Global**
Government Tasks:	Diplomatic Security/ Force Protection	Foreign Capabilities Assessment	Strategic Warning from Intelligence
Business Tasks:	Threat Analysis, Personal Risk Analysis	Business/Competitive Intelligence	Business Scenario Planning

Threat analysis in the business environment depends on the open exchange of information between companies, as it is widely recognized that no one benefits from other companies encountering unnecessary risk or danger to their personnel. On the other hand, at the corporate level, competitive business intelligence relies on the protection or discovery of important corporate data. In the public security environment, diplomatic security and

[92] Jonathan Tetzlaff, Area Director, Security Research and Analysis, Amoco Corporation, personal correspondence with editor, 24 October 1997.

force protection for a government's own citizens, and for personnel in multilateral operations, is in the best interests of all. Conversely, foreign capabilities assessment operates in the context of a zero-sum game among countries, with potential winners and losers of the tactical advantage.

When the very survival of a corporation or country is at stake vis-a-vis other players in their respective environments, a global or strategic model applies. At this level, strategic warning intelligence takes center stage in the government security setting, and its counterpart — strategic scenario planning — achieves value in the private sector. Scenario planning has been used advantageously by some companies. The Shell Oil Company, for example, used scenario planning to justify disinvestment in oil exploitation infrastructure prior to the worldwide fall in oil demand in the 1980s. The company rose from 14th to 2nd place among oil multinationals, as overinvested companies lost billions.[93] The alternative to taking global or strategic intelligence action is to allow threats to emerge and to bring company or government officials to the realm of crisis management. There, fundamental government or business interests are at stake, and the outcome is more likely to be left to the vagaries of impulse and chance than to the considered judgment and actions of corporate or government leaders.

Private sector intelligence services can consider which elements of the national intelligence model may apply in their own domain. Will the organization require central coordination of diverse elements as the national system does, or might the intelligence unit more closely resemble a single collector or producer agency with a simpler management structure? Will an advisory group mediate between intelligence producers and customers, and does the intelligence service require its own staff to coordinate operations? Will the service be organized functionally into collection and production elements, or perhaps topically? Is

---

[93] Robbie E. Davis-Floyd, "Storytelling Corporate Futures: The Shell Scenarios," *International Journal of Futures Studies* 1 (1995-1997), on-line at http://www.systems.org/HTML/journals.htm, accessed 3 December 1997. The purpose of scenario planning is to force business managers and executives to face future uncertainties squarely by elaborating and evaluating the likelihood and impact of alternative hypothetical business environments. Dissenters are valued, rather than avoided, and, as in government intelligence channels, information is proactively developed to champion and refute the various scenarios as "controllable" pathways to the future. Recent reviews of business scenario planning include Kathy Moyer, "Scenario Planning at British Airways — A Case Study," *Long Range Planning* 29, No. 2 (April 1996): 172-181; Francoise Hecht, "The Aha! Factor," *Director* 50, No. 12 (July 1997): 59; and Ian Smith, "Avoiding Future Shock," *Director* 50, No. 12 (July 1997): 56-59.

A seminal work on the analytical environment for strategic warning in government intelligence is Ephraim Kam, *Surprise Attack* (Cambridge, MA: Harvard University Press, 1988). Although Kam focuses on military attack scenarios, the arena for strategic warning in government intelligence work has expanded as international security concerns shift toward economic competition and away from military confrontation. The convergence of economics and security signals a need for benchmarking the intelligence process, and could presage an era of greater collaboration between cells of intelligence analysts and policymakers at the highest levels, not unlike the give and take that characterizes successful business scenario planning.

the intelligence service an independent organization with external customers, or does it operate within a parent organization? If the latter, does each department, such as Marketing, Planning, or Research require its own tailored intelligence support? Does the chief executive require a centralized intelligence service, by whatever name, to assist in corporate policy-making? Should the service develop contingency plans for providing time-sensitive support in a crisis situation? On a larger scale, should intelligence services within an industry pool their resources for mutual benefit in a crisis environment, or to proactively adapt to a changing environment, as does the national Intelligence Community? The answers to these questions may help private sector intelligence organizations determine how closely to pattern their structure after that of the national intelligence system.

Managing Analysis and Production

Intelligence managers in government and industry need to decide how to organize the production process just as they need to determine the structure of the intelligence service as a whole. Typical methods of assigning analysts are by target function, geographical region, technical subject, or policy issue. The intelligence service may task analysts to concentrate on one type of source information, or to merge all available sources to produce "finished" intelligence or estimates. Some industries will need analysts to specialize in certain technical subject areas or complex issues, while large corporations may assign intelligence analysts to each of several departments such as Research or Product Development. Small independent intelligence services may require personnel to perform all the functions of the intelligence process from needs assessment to production and performance evaluation. In that case, analysts might be assigned to a particular customer account rather than a specific topic area. Part VIII of this primer presents findings on the attributes of intelligence analysts that may prove useful in determining how to allocate human resources in the intelligence production process.

> Some characterizations of the analytic mission...seem to emphasize serving the policymaking process as an abstraction: to tell it like it is, to level the playing field, to keep the policymakers honest, to be right on the record.... But excessive adherence to these attributes can cause overproduction of assessments that feature what analysts think policy officials should want to know, and underproduction of assessments featuring what officials think they need from...analytic specialists.... To provide the requisite benefits for policymakers, the analytic assessments of the intelligence production unit have to deliver a high order of understanding and insight that can support sound decisionmaking. One should avoid a definition of effective analysis that emphasizes accurate prediction...or one that centers on whether or not a policy worked.[94]

> Furthermore, managers can take the initiative in transforming intelligence into a proactive service. Managers who are isolated from the intelligence customer tend to monitor the quantity of reports produced and level of polish in intelligence products, but not the utility of the intelligence itself.[95]

---

[94] Davis, *Opportunity Analysis*, 2-3.
[95] Davis, *Opportunity Analysis*, 10.

> But policy officials will seek information and judgment from the source that provides it at the lowest personal cost, including the mass media, no matter how much money the intelligence organization is spending to fund analysis on their behalf. Thus, managers need to learn to ask for and accept opportunity analysis included in intelligence products, not remove it as inappropriate during the review process. One way to ensure that analysts produce truly useful intelligence is for managers to take an inventory, say twice per year, of the specific professional interests of their key [customers]. Policy officials are more comfortable thinking in terms of outputs than of inputs. Thus, the inventory should be couched in terms of the policymakers' objectives — their hopes and fears — and not in terms of their "intelligence priorities."... The intelligence manager should then take responsibility for converting the inventory into signals for the restructuring of collection, research, and analytic production.[96]

Evaluating the Intelligence Process

Beyond organizing and monitoring intelligence production, an additional management responsibility is to evaluate the intelligence service's overall mission performance. From the manager's perspective, intelligence products are not the only output from the intelligence process; therefore, products are not the only focus of rigorous self-evaluation. In the course of its operations, the intelligence unit expends and generates significant amounts of financial and political capital. Careful examination of this commodity flow may yield key insights into process improvement. Internal review procedures may thus include measures of how well the intelligence service and its components organize their work, use funds, allocate materiel and human resources, and coordinate with parent and customer organizations, all from the self-interested perspective of the intelligence service itself. To assist them in this effort, managers may evaluate the sub-processes and interim products of the Needs Definition, Collection, Processing, Analysis, and Production phases of the intelligence process in terms of Brei's Intelligence Values: Accuracy, Objectivity, Usability, Relevance, Readiness, and Timeliness.

Furthermore, to put a human face on intelligence process, conscientious managers may wish to include in their internal review a frank analysis of their own personnel management record. Perhaps a new definition of "customer" is in order for carrying out this aspect of intelligence evaluation. Seeing the members of the intelligence service as customers of management, and of each other, can enable managers to create a work culture in which each person's needs and talents are respected and incorporated into the organization's mission. By subscribing to the philosophy that a happy workforce is a productive workforce, managers may also achieve the organizational goal of satisfying external customer requirements. With this purpose in mind, principles for matching intelligence personnel to appropriate job assignments are discussed in the next Part of this primer.

[96] Davis, *Opportunity Analysis*, 6.

PART VIII
PORTRAIT OF AN INTELLIGENCE ANALYST

The efficacy of the intelligence process described in the foregoing chapters depends upon personnel who are both able and willing to do the specialized work required. Through the findings of several government studies, this section presents the ideal characteristics of the central figure in value-added production — the intelligence analyst. According to these studies, the successful intelligence analyst brings to the discipline certain requisite knowledges and abilities, or has a high aptitude for acquiring them through specialized training; is able to perform the specific tasks associated with the job; and exhibits personality traits compatible with intelligence analysis work. This profile will remain valid in any setting modeled after the national security intelligence system.

The cognitive, performance and personality attributes of the intelligence analyst are explained below. Readers are encouraged to apply this information in accordance with their own particular circumstances. For example:

> Incumbents and individuals considering employment in intelligence analysis may deepen their self-awareness and assess their potential for success and satisfaction in this profession.
>
> Educators and recruiters may identify and prepare candidates for employment in intelligence analysis.
>
> Managers and supervisors may make enlightened decisions about selection, placement, tasking and evaluation of intelligence analysis personnel.

Cognitive Attributes

An individual's analytic skill results from a combination of innate qualities, acquired experience, and relevant education. Psychologists call these mental faculties cognitive attributes, and further divide them into two types: abilities (behavioral traits, being able to perform a task) and knowledges (learned information about a specific subject).[97] Whereas an individual's cognitive abilities are relatively fixed by the time he or she enters the job market, knowledges are situation-specific and can be acquired through training.[98]

According to a recent formal job analysis of selected intelligence analysts conducted by the NSA Office of Human Resources Services, important cognitive abilities for intelligence analysis include written expression, reading comprehension, inductive reasoning, deductive reasoning, pattern recognition, oral comprehension, and information

---

[97] Mark H. Haucke, Industrial Psychologist, NSA, interview with the author, 25 May 1995.
[98] Melissie C. Rumizen, Benchmarking Manager, NSA, interview with the author, 5 July 1996.

ordering.[99] Furthermore, both junior analysts and experienced analysts or supervisors agree that high levels of these abilities are necessary for performing the intelligence analysis job. The abilities are defined in the box below.

Cognitive Abilities Required of Intelligence Analysts[100]

Written Expression: The ability to use words and sentences in writing so others will understand. Involves knowledge of the meanings and distinctions among words, knowledge of grammar, and the ability to organize sentences and paragraphs.

Reading Comprehension: The ability to read and understand written sentences and paragraphs.

Inductive Reasoning: The ability to combine separate pieces of information, or specific answers to problems, to form general rules or conclusions. Involves the ability to think of possible reasons why things go together. Also includes coming up with a logical explanation for a series of events that seem unrelated.

Deductive Reasoning: The ability to apply general rules to specific problems to come up with a logical resolution. Involves deciding if the resolution makes sense.

Pattern Recognition: The ability to identify or detect a known pattern (a figure, word, or object) that is hidden in other material.

Oral Comprehension: The ability to listen and understand spoken words and sentences.

Information Ordering: The ability to follow a rule or set of rules in order to arrange things or actions in a meaningful order. The rule or set of rules to be used must already be given. The things or actions to be put in order can include numbers, letters, words, pictures, procedures, sentences, and mathematical or logical operations.

One set of junior analysts and another of supervisors were separately asked to judge the importance of each of these abilities in performing the intelligence analysis job (see Table 14). Junior analysts assign greater importance to two abilities (written expression and inductive reasoning), but significantly less importance to pattern recognition, than do their supervisors. These results have implications for staffing the intelligence analysis job in both the government and private sector. For example, if junior analysts place greater importance on written expression than their supervisors do, they may be frustrated to receive less training, tasking and recognition than needed for this aspect of their job. The discrepancies in the rankings among the five abilities judged most important by the two groups can be addressed individually by managers. However, the rankings provide some useful generalizations for identifying cognitive attributes applicable to any intelligence environment. In the case of the National Security Agency, the results presented here led

[99] Data were generated by Mark H. Haucke, Industrial Psychologist, using a Management Research Institute (MRI) survey instrument presented in *Ability and Knowledge Requirements* (Bethesda, MD: MRI, 1994).

psychologists to design a job-relevant pre-employment aptitude exam for intelligence analysts.

Table 14: Comparative Ranking of Cognitive Abilities Thought to Be Required for Intelligence Analysis

(The lower the number on the 1 to 5 scale, the higher the perceived importance of the ability)

Source: Author and Haucke Study

Cognitive Ability	GROUP 1 (23 Junior Analysts - less than 7 years experience)	GROUP 2 (18 Supervisors — older generation; Ave. Years experience: 19)
Written Expression	1	3
Reading Comprehension	2	1
Inductive Reasoning	2	3
Deductive Reasoning	3	2
Pattern Recognition	3	1
Oral Comprehension	4	4
Information Ordering	5	4

Unlike the abilities categories, areas of knowledge for government intelligence specialists do not necessarily apply to their private sector counterparts. The formal job study of government intelligence analysts revealed that knowledge of military-related and technical subjects, not surprisingly, was prevalent among the individuals in the research group.[101] However, in either public or private sectors, managers can hire and train personnel to apply the requisite knowledges in a given job. A next logical step is to define the components of the intelligence analysis job, to be able to plan and assess individual job performance.

Performance Factors

Even as the analysis described above examined cognitive inputs to the job, a related performance review project, also at NSA, described intelligence analysts' output on the job. As part of this review, supervisors of intelligence analysts placed their subordinates' mission-essential job tasks into seven categories. Next, they evaluated the job performance of

[101] Data courtesy of Dr. Mark Haucke.

intelligence analysts according to those criteria. Researchers found a strong positive correlation between aptitude for intelligence analysis (as measured in the knowledges and abilities survey) and successful job performance (as rated by supervisors).[102] Following is a brief description of the seven intelligence analysis performance categories:[103]

Data Collection - Research and gather data from all available sources.

Data Monitoring - Review flow of scheduled incoming data.

Data Organizing - Organize, format, and maintain data for analysis and technical report generation.

Data Analysis - Analyze gathered data to identify patterns, relationships, or anomalies.

Data Interpretation/Communication - Assign meaning to analyzed data and communicate it to appropriate parties.

Computer Utilization - Use computer applications to assist in analysis.

Coordination - Coordinate with internal and external organizations.

This concise inventory echoes the intelligence process and illustrates the complexity of the intelligence analyst's job. It also serves as a blueprint for managers as they design intelligence organizations and individual personnel assignments. In particular, the analyst's job description should reflect these expected behaviors for purposes of recruitment, selection, placement, training, and performance evaluation. The intelligence organization should also be structured physically and logically to enable these functions to occur. Managers should consider how all these factors combine to determine the effectiveness of individual analysts, intelligence units, and even national agencies or private firms that produce and use intelligence.

Personality Traits

The third component of the intelligence analyst profile, personality traits, addresses the individual's preferences for behaving in certain ways under specific conditions. Adults tend to exhibit the same set of behavior preferences consistently in familiar situations. This behavior pattern may be identified as a personality type. One well-known instrument for identifying an individual's personality type is the Myers-Briggs Type Indicator (MBTI).[104] The following discussion of the intelligence analyst's personality is based upon MBTI research.

---

[102] Haucke interview, 13 June 1996.

[103] Standardized categories are presented in an MRI performance evaluation booklet, *Job Dimension Ratings* (Bethesda, MD: MRI, 1995).

[104] See Isabel Briggs Myers, *Introduction to Type*. (Palo Alto, CA: Consulting Psychologists Press, 1980), and Ronald D. Garst, *Intelligence Types: The Role of Personality in the Intelligence Profession*. 2d printing, (Washington, DC: Joint Military Intelligence College, August 1995).

> Personality types are associated with more or less predictable patterns of behavior — meaning that people of different personality types approach tasks differently and have different tastes, interests, likes and dislikes. For example, some people would rather work alone while others prefer to work with other people. Some enjoy working with concrete information, others with abstract information. Some decide on the basis of personal reasons, some on cold, hard logic. And finally, some people enjoy making decisions while others are reluctant to decide because of perceived information inadequacy.[105]

Research at the Joint Military Intelligence College (JMIC) demonstrates that intelligence professionals exhibit a pattern of personality traits that sets them apart from the U.S. population as a whole. In this regard, intelligence professionals are no different from many others, for every profession has its own distinct pattern of personality traits. A significant percentage (21 percent) of those who choose to pursue employment in national security intelligence tend to express the following behavior preferences: orientation to the inner world of ideas rather than the outer world of things and people, tendency to gather factual information through the senses rather than inspiration, proclivity to make decisions on the basis of logic rather than emotion, and an eagerness to seek closure proactively instead of leaving possibilities open. In contrast, researchers found that people who exhibit the opposite set of personality traits are almost non-existent among intelligence professionals. The chart below summarizes the terminology by which the MBTI describes personality traits. Note that the most frequently occurring type among the respondents to the JMIC survey exhibit the traits I, S, T and J.[106]

The JMIC data are based on a large sample of government intelligence students and practitioners. Persons engaged in the study or practice of other forms of intelligence, particularly in the private sector, should not expect their personality type to match the JMIC profile. However, intelligence practitioners who choose and successfully apply the intelligence methodology presented in this primer are likely to exhibit the same personality traits as those identified in government practitioners. Because people tend to be satisfied and productive in their work if their own personalities match the corresponding behaviors suitable to their jobs, this research tying personality traits to the intelligence profession can help individuals consider their general suitability for certain types of intelligence work.

---

[105] Garst, *Intelligence Types*, 1.
[106] Garst, *Intelligence Types*, 9.

Personality Aspects Measured by the MBTI[107]

Orientation to the world

E=Extraversion	**I=Introversion**
Orientation to the outer world of things and people, interacting with and affecting them	Orientation to the inner world of ideas and concepts, solitude and self-awareness

Perception: non-rational processes; awareness of things, people, events or ideas, selection of stimuli to attend to

S=Sensing	**N=Intuitive**
Gather information by physical sensation; oriented to facts, detail and the present	Gather information by inspiration, unconscious processes; oriented to possibilities, relationships, and the future

Judgment: ways of deciding, evaluating, choosing, selecting

T=Thinking	**F=Feeling**
Decide on basis of logic, impersonal objective criteria, cause and effect, laws and justice	Decide on basis of subjective, personal criteria and values, and how decisions affect other people and relationships.

Preference for Closure as manifested through behavior using S/N or T/F Functions

J=Judging	**P=Perceiving**
Want to have an issue or project completed so they can move on; work takes precedence over play; proactive	Leave decisions open to modify response in accordance with new information; use play to make work more enjoyable; reactive

[107] Compiled from Garst, *Intelligence Types*, 4-9.

PART IX
DEFENSIVE MEASURES FOR INTELLIGENCE

> [A]s information becomes more and more a factor of production, of tangible worth for its own sake, the value of the special knowledge that is the essence of intelligence will command a higher price in the global information age marketplace than will the generally available knowledge. Therein lies the most ancient and, at the same time, the most modern challenge to the future of intelligence — protecting it.
>
> *— Goodden, in Dearth and Goodden, 415.*

Beyond Intelligence Process: Protecting the Means and the Results

An intelligence organization's openness about its validated intelligence methods is of course tempered by self-defense considerations. Two arenas that are complementary to intelligence production, Operations Security (OPSEC) and Information Systems Security (INFOSEC), focus on how practitioners can avoid revealing proprietary or classified information. OPSEC measures protect the specific actions taken to produce intelligence, whereas INFOSEC protects from disclosure the intelligence information used in production, as well as the resulting intelligence products.

In government circles, standard procedures guide the implementation of OPSEC and INFOSEC measures. In the private sector, trial and error may predominate. Companies that emphasize methods for exploiting publicly available information about their competitors may show little regard for protecting themselves from being targeted by the same means they have employed to target others. Furthermore, the trend toward greater computerization of the workplace, including on-line information systems and networked services, makes both government and commercial organizations vulnerable to being exploited themselves.[108]

For example, the Boeing Corporation discovered in 1992 that amateur computer hackers had found their way into the company's computer network, and used stolen passwords to open pathways to proprietary information stored in other computers in industry, government, and education organizations.[109] Prosecuting this case cost Boeing, the FBI, and other law-enforcement authorities considerable time and money.[110] This case was trivial

---

[108] Keen insights into such vulnerabilities are presented in Ira Winkler, *Corporate Espionage: What It Is, Why It Is Happening in Your Company, What You Must Do about It,* (Rocklin, CA: Prima Publishing, 1997).

[109] Rhonda E. MacLean, Senior Manager, Boeing Computing and Communications Security, "The Boeing Hacker Incident," *DODSI Security Awareness Bulletin* Number 1-94 (Richmond, VA: Department of Defense Security Institute, August 1994), 19.

[110] MacLean, 20-21

compared to other well publicized security breaches in government and industry.[111] Yet, at the March 1996 international SCIP conference, of 72 presentations held during four days, only three specifically addressed counterintelligence or security.[112] One reason for this is that businesses may be reluctant to admit their own vulnerabilities in the presence of competitor firms. However, as a Boeing computer security officer has noted, corporations are beginning to realize that admitting flaws in information system defenses is the first step toward preventing future violations, and business and government should work together toward this goal.[113]

In light of the tendency to overlook OPSEC and INFOSEC implementation, the remainder of this section develops an instructional overview of the basic information that government and business personnel should know to protect their activities from unauthorized exploitation. Indeed, for the health of U.S. commerce and national security activities, everyone needs user-friendly information on how to protect proprietary information. Even the most sophisticated corporations have difficulty keeping up with the hazards of the information age; it was not until 1992 that Boeing mandated that all company computer users attend a security awareness briefing, and this was after the firm suffered a major breach of information security. Now Boeing sees "...the importance of information security to our company's long-term competitiveness..." and considers awareness activity as the cornerstone to a good security program.[114]

Operations Security

OPSEC is essential to the intelligence function in both the national security and business environments. OPSEC denies adversaries information about one's own operational capabilities and intentions by identifying, controlling, and protecting indicators associated with the planning and conduct of those operations and other related activities. An adversary is not necessarily a belligerent enemy: In OPSEC terms, an adversary is any entity that acts against one's own interest or actively opposes one's own goals.[115]

To protect an intelligence operation, practitioners can adopt an adversary's perspective. For example, factors at risk in one's own environment can be categorized into critical information, indicators, and vulnerabilities, described briefly below.

---

[111] Examples include those cited in Clifford Stoll, *The Cuckoo's Egg*, (New York: Pocket Books, 1990) and Winn Schwartau, *Information Warfare: Chaos on the Electronic Superhighway*, (New York: Thunder's Mouth Press, 1994).

[113] MacLean, 22.

[114] MacLean, 22.

[115] National Cryptologic School, Information Security Department, *Operations Security Fundamentals*, (Fort Meade, MD: 1994), 2.

Factors at Risk in Intelligence Operations	
Critical Information	Details of capabilities and operations directed against an adversary
Indicator	Detectable actions and publicly available information revealing critical information
Vulnerability	Conditions making exploitable information available to the adversary

Countermeasure options to prevent an adversary from exploiting these factors include: eliminating the indicators altogether, concealing indicator activities, disguising indicator activities, and staging deceptive (false) activities.[116]

The practice of OPSEC is so important to national security that a federal organization has been established as its advocate. As a result of the 1988 Presidential Directive on national operations security, the Interagency OPSEC Support Staff (IOSS) was formed, with the National Security Agency as its director. The core membership of the IOSS includes the Department of Defense, Department of Energy, Central Intelligence Agency, Federal Bureau of Investigation, and General Services Administration.[117] Other executive and national security bodies, including the military services, have representation on the National Operations Security Advisory Committee, which advises the Executive Branch on the practice of OPSEC.[118] The IOSS may be contacted for assistance at:

Interagency OPSEC Support Staff, 6411 Ivy Lane, Suite 400, Greenbelt, MD 20770-1405 Telephone (301) 982-2313/0323.

Information Systems Security

Information Systems Security (INFOSEC) refers to the protection of information that an organization uses and produces in the course of its operations. Today, this means protecting complex electronic networks. Government and business depend upon computerized systems for everything from banking, communications, and data processing to physical security and travel reservations. To the casual observer, INFOSEC may seem the domain of a few technical specialists, or the exclusive concern of the military or intelligence agencies. But INFOSEC is the responsibility of everyone who has ever used a telephone, computer, or automatic bank teller machine.[119]

[116] National Cryptologic School, 9.

[117] National Security Agency, Introduction.

[118] National Operations Security Advisory Committee, *National Operations Security Doctrine*, (Greenbelt, MD: Interagency OPSEC Support Staff, January 1993): unnumbered back of first and second physical pages from beginning.

[119] A basic reference on INFOSEC is the National Research Council book *Computers at Risk: Safe Computing in the Information Age*, (Washington, DC: National Academy Press, 1991).

> INFOSEC today [involves] significantly more than the traditional security offered by encryption. Network vulnerability to adversarial intercept, tampering, or destruction of data mandates INFOSEC solutions that ensure the authentication, integrity, and availability of classified and unclassified information created, stored, and processed on [information] systems. ... Such solutions must enable the interconnection of Command and Control, intelligence, and support systems and must allow for the commingling of critical information of different classification levels on a common transport backbone. INFOSEC solutions must be flexible, configurable, and result from a risk management scenario that balances the costs and availability of countermeasures against actual threats to, and vulnerabilities of, networks and systems. Finally, INFOSEC must accomplish all of this in an environment in which networks are neither owned nor controlled by [the government] and resources are severely constrained.[120]

Each intelligence organization and activity must tailor its INFOSEC measures to its particular technologies and operational practices, weighing the costs of such measures against their value in safeguarding the mission. A three-dimensional model of INFOSEC, illustrated below, may guide the intelligence service in implementing protective measures and assessing their adequacy. The first dimension addresses the need to understand the vulnerability of information as it passes through different stages of use. The second dimension includes the key characteristics of information that must be preserved for it to remain useful and secure. The third dimension covers the general categories of INFOSEC tools that the intelligence service may employ. Each element of the model is dependent on the others.[121] Together, these interlocking pieces make up a comprehensive INFOSEC strategy appropriate to the public or private sector.

Dimensions of INFOSEC[122]

Information States:	Transmission, Storage, Processing
Critical Information Characteristics:	Confidentiality, Integrity, Availability to Legitimate Users
Countermeasures:	Technology, Policy/Practice, Education

Role of the Federal Government

Federal agencies, including Intelligence Community members, play key roles in helping both government and businesses learn and practice INFOSEC. The two primary authorities for INFOSEC are the Department of Commerce and the Department of

[122] Fisher.

Defense. Organizations within these departments provide INFOSEC services to their respective constituencies within the framework of national information policies established by the Executive Branch. The following overview begins with a summary of Executive Branch policy.

National Information Policy

> The vision of the National Information Infrastructure — or NII — is [as] a vast accessible network of networks that supports communications and information processing to create jobs, increase productivity, improve access to government services, and encourage community networking. The NII is also the wide array of information of all kinds within the networks, whether it is stored, processed, or communicated. Finally, it includes the people... who are today creating and using the NII.[123]

The federal government's role in the NII is to provide a sound legal and policy framework, in conjunction with state, local and Native American governments. Current initiatives include assuring universal service on the NII, thereby enabling open access to government information; protecting intellectual property rights; protecting the privacy of individual information; and stimulating the development of advanced information technologies, including security technologies.[124] The Office of Management and Budget's (OMB) national information security authority covers the development, promotion, implementation and evaluation of government policies and practices for information resource management.[125]

A multi-agency group, the national Information Infrastructure Task Force (IITF), coordinates the federal role in the NII through three committees: the Committee on Applications and Technology, the Telecommunications Policy Committee, and the Information Policy Committee. The OMB's Office of Information and Regulatory Affairs chairs the IITF's Information Policy Committee. As noted below, elements of the Commerce Department chair the other two IITF committees. In addition, the NII Security Issues Forum coordinates NII security activities throughout the IITF and the federal government.[126]

Commerce Department

The Commerce Department's Assistant Secretary for Communications and Information heads the National Telecommunications and Information Administration (NTIA).

[126] Katzen.

The NTIA's information security responsibilities include: serving as the principal executive adviser to the President on telecommunications and information policy; serving as the principal federal telecommunications research and engineering laboratory, through the Institute for Telecommunication Sciences in Boulder, Colorado; and providing grants to programs that promote the development and provision of advanced telecommunications technologies for the public. The NTIA chairs the IITF's Telecommunications Policy Committee.[127]

The Commerce Department's Technology Administration includes two components involved in information security, the Office of Technology Policy (OTP) and the National Institute for Standards and Technology (NIST).

> The primary role of the OTP is to offer assistance to private sector and government communities in advocating and pursuing policies that maximize the impact of technology on economic growth, and by exercising leadership to define the role of government in supporting U.S. industrial competitiveness in the post-cold war environment. ... NIST's primary mission is to promote U.S. economic growth by working with industry to develop and apply technology, measurements, and standards.[128]

NIST is the national authority for developing government-wide standards and guidelines for protecting unclassified but sensitive information, and for developing government-wide training programs.[129] NIST also chairs the IITF's Committee on Applications and Technology.[130] Finally, NIST maintains the Computer Security Resource Clearinghouse (CSRC) as a resource for anyone with an interest in computer security. It is available on-line 24 hours a day, seven days a week at no charge. The CSRC provides access to crisis response information on security-related threats, vulnerabilities, and solutions, and is a general index to computer security topics such as general risks, privacy, legal issues, viruses, assurance, policy, and training.[131]

Defense Department

The Secretary of Defense is the Executive Agent for National Security Telecommunications and Information Systems Security.[132] As a whole, Department of Defense (DoD) information and communications systems are termed the Defense Information Infrastructure (DII). Under the direction of the Secretary of Defense, three DoD agencies form the

core DII INFOSEC team: the Defense Intelligence Agency (DIA), the Defense Information Systems Agency (DISA), and the National Security Agency (NSA). Although notionally the DII is a dedicated system for proprietary and classified national defense information, in fact over 95 percent of its communications are carried on the public switched networks of the NII.[133] Thus, DoD expertise in information security doctrine and technology makes the organizations explained below key resources for other government organizations and for the private sector.

The Defense Intelligence Agency, as the central authority for military intelligence, provides INFOSEC threat analysis and support to the DII.[134] Another agency, DISA, is responsible for planning, developing, and supporting command, control, communications, and information systems that serve the needs of the National Command Authorities under all conditions of peace and war; it further ensures the interoperability of all DII systems and those national and/or international commercial systems that affect the DISA mission.[135] NSA acts as the National Manager for National Security Telecommunications and Information Systems Security in the name of the Secretary of Defense. In this capacity, NSA is the focal point for U.S. government cryptography and for the security of national security telecommunications and information systems.[136] NSA provides DISA with the tools, techniques, products, services, and security management structures to protect the DII, through its "V" Group, the customer service and engineering organization for information systems security.[137] Within NSA, the National Computer Security Center (NCSC) conducts technical evaluation of the protection capabilities of commercially produced and supported systems.[138] Through its Information Systems Security Research Joint Technology Office (ISSR-JTO), NSA coordinates with DISA and the DoD's Advanced Research Projects Agency on engineering INFOSEC technologies. The ISSR-JTO provides a first line of defense for defensive information warfare, and permits electronic commerce between DoD and its contractors. It also maintains research and technology interfaces with the military departments, national labs, universities, and industry.[139] NSA coordinates with the National Institute for Standards and Technology (NIST) in matters of common concern.[140] Together, DIA, DISA, and NSA operate the DoD Center for Information Systems Security.[141]

[141] DISA, "INFOSEC and the DII," *DISSPatch* 4, No. 1 (3rd Quarter 1996): 7.

The Department of Defense's INFOSEC Program Management Office (IPMO) is a joint DoD/DISA/NSA organization charged with executing centrally managed INFOSEC functions within the DoD.[142] The IPMO provides operational protection and detection capability for the DII against information exploitation, manipulation, or destruction. It administers DoD-wide INFOSEC training and manages the DoD INFOSEC Technical Services Contract. The IPMO conducts vulnerability, threat, and operational analyses of the DII, provides security policy guidance and oversight to DISA programs, and certifies DISA and non-DISA systems that connect to the DII.[143] The IPMO also provides support to the Assistant Secretary of Defense for Command, Control, Communications, Computers, Intelligence, Surveillance and Reconnaissance (ASD/C4ISR).[144] Another DoD body, chaired by the ASD/C4ISR, also has a role in INFOSEC. Under the purview of the National Security Council, the National Security Telecommunications and Information Systems Security Committee (NSTISSC) advises Executive Branch agencies and Departments on the status of national security systems. Its two subcommittees focus on telecommunications security and information systems security, respectively. NSA provides the NSTISSC secretariat.[145]

In addition, the DoD Security Institute (DODSI) promotes security awareness and compliance with security procedures in DoD by offering training courses to security personnel in DoD and DoD-related industry, publishing security awareness bulletins, and disseminating information to security trainers on security and counterintelligence.[146]

INFOSEC for Everyone

The national authorities for INFOSEC described above evolved out of the need to protect the fundamental role of information in a democratic society and market economy. They help strike the balance between free exchange of information and privacy, and between free enterprise and regulation. Government-sponsored information policy and technology set the standards upon which nearly every facet of public and private life is based. Citizens receive basic services through government-created or -regulated information infrastructure, including automatic payroll deposit to employee bank accounts, cellular telephone service, electronic commerce via the Internet, air and rail traffic control, emergency medical services, and electrical power supply.

Such services contribute not only to the citizen's quality of life, but to the very functioning of the nation. Information is the lifeblood of society and the economy. Imagine the chaos that would reign if the government, the military, banks, businesses, schools, and hospitals could not communicate reliably. Life would come to a halt.

[145] NSA, Chapter 3, B.a, B.b, and B.c.
[146] DODSI, front cover, 12, 18.

INFOSEC is designed to protect society from inadvertent or intentional harm to these key functions. The same free access to information that makes society flourish also makes it vulnerable to damage, attack or exploitation. For example, passive threats such as shoddy equipment, faulty software, or negligent personnel can disrupt service and destroy information. Hostile threats include thrill-seeking computer hackers and belligerent foreign adversaries who deliberately target sensitive government and public information networks with the aim of disrupting or destroying key operations, such as military projects or power grids.[147] Comparable scenarios within the business sector, to include information sabotage and deception actions against competitors, are at least plausible. Therefore, basic knowledge of INFOSEC may benefit citizens in all walks of life. Addresses and phone numbers for the INFOSEC agencies that can assist the public are listed at the end of this chapter.[148]

Government expertise in information technology and policy has made it the authority specifically on protecting intelligence operations. The private sector may also benefit from this expertise by applying INFOSEC measures in business intelligence. In brief, successful intelligence operations rely on secure transmission, storage, and processing of the information used. The information itself must be exchanged only among legitimate users, and it must retain its intended meaning and be available to users upon demand. Finally, intelligence information and products can be protected through technology (access control, encryption), through security policies and practices, and through educating the workforce, as with this document.

EPILOGUE

This primer has reviewed government intelligence production practices in building-block fashion. It has also explored the defensive measures comprising information security and operations security, which are integral to all the building blocks, and are equally applicable to private businesses and government organizations. Finally, the primer has drawn a cognitive, behavioral and personality profile of the central figure in intelligence production — the intelligence analyst. In the spirit of benchmarking, this document invites a reciprocal examination of best practices that may have been developed by private businesses, and of principles that may have been derived from other academic studies of intelligence-related processes.

Although this effort reflects a government initiative, in fact the government Intelligence Community may receive the greater share of rewards from benchmarking its own process. Potential benefits to the Community include an improved public image, increased self-awareness, more efficient recruitment through more informed self-selection by candidates for employment, as well as any resultant acquisition of specialized information from subject matter experts in the business and academic communities.

Primary advantages for the government's partners in the exchange of information on best practices could be greater understanding of how tax dollars are spent, and the opportunity to transfer an appreciation of government professional intelligence production, security, and staffing methods into academic curricula and business operations.

For all participants in benchmarking, releasing information is actually a way of controlling it, a way of depicting and fostering an accurate organizational image rather than allowing others to draw and disseminate erroneous characterizations. For the U.S. Intelligence Community in particular, any initiative in benchmarking the intelligence process fulfills a charge of the recently completed Report on the Community's Roles and Capabilities: to improve its performance through closer relationships with customers, including the private sector.

GLOSSARY

ASD/C4ISR	Assistant Secretary of Defense for Command, Control, Communications, Computers, Intelligence, Surveillance and Reconnaissance
BI	Business Intelligence

ABOUT THE AUTHOR

Lisa Krizan has been a researcher with the Department of Defense since 1987. She received a master's degree from the Joint Military Intelligence College in 1996 and developed many of the ideas for this paper as part of her thesis on benchmaking the intelligence process. A second-generation intelligence scholar, she follows the example set by her father, 1972 Defense Intelligence College graduate Allen J. Montecino, Jr., Colonel, USAF (Ret).

FOREWORD

Marine Corps Warfighting Publication (MCWP) 2-22, *Signals Intelligence*, serves as a basic reference for understanding concepts, operations, and procedures for the conduct of signals intelligence (SIGINT) operations in support of the Marine air-ground task force. This publication complements and expands on Marine Corps Doctrinal Publication 2, *Intelligence*, and MCWP 2-1, *Intelligence Operations,* which provide doctrine and higher order tactics, techniques, and procedures for intelligence operations.

The primary target audience of this publication is intelligence personnel responsible for planning and executing SIGINT operations. Personnel who provide support to SIGINT or who use the results from these operations should also read this publication.

MCWP 2-22 describes aspects of SIGINT operations, including doctrinal fundamentals, equipment, command and control, communications and information systems support, planning, execution, security, and training. Detailed information on SIGINT operations and tactics, techniques, and procedures is classified and beyond the scope of this publication.

MCWP 2-22 supersedes Fleet Marine Force Manual 3-23, (C) *Signals Intelligence/Electronic Warfare Operations* (U), dated 21 September 1990.

Reviewed and approved this date.

BY DIRECTION OF THE COMMANDANT OF THE MARINE CORPS

To Our Readers

Changes: **Readers of this publication are encouraged to submit suggestions and changes that will improve it. Recommendations may be sent directly to Commanding General, Marine Corps Combat Development Command, Doctrine Division (C 42), 3300 Russell Road, Suite 318A, Quantico, VA 22134-5021 or by fax to 703-784-2917 (DSN 278-2917) or by E-mail to smb@doctrine div@mccdc. Recommendations should include the following information:**

- **Location of change**
  - **Publication number and title**
  - **Current page number**
  - **Paragraph number (if applicable)**
  - **Line number**
  - **Figure or table number (if applicable)**
- **Nature of change**
  - **Add, delete**
  - **Proposed new text, preferably double-spaced and typewritten**
- **Justification and/or source of change**

Additional copies: **A printed copy of this publication may be obtained from Marine Corps Logistics Base, Albany, GA 31704-5001, by following the instructions in MCBul 5600, *Marine Corps Doctrinal Publications Status*. An electronic copy may be obtained from the Doctrine Division, MCCDC, world wide web home page which is found at the following universal reference locator: http://www.doctrine.quantico.usmc.mil.**

Unless otherwise stated, whenever the masculine or feminine gender is used, both men and women are included.

Chapter 1

Fundamentals

All military forces use the electromagnetic spectrum to command and control operating forces acquire targets, guide weapons, and direct supporting arms. These military forces also use the electromagnetic spectrum to collect, process, and report intelligence and to support other administrative and logistics operations. Most facets o military operations involve the use of some device or system that radiates or receives electromagnetic energy via air waves, metallic cable, or fiber optics. Radios, radars, sensors, smart munitions, telephone systems, and computer networks use electromagnetic radiation. Both complex and unsophisticated military organizations depend on these systems and their inherent use of the electromagnetic spectrum. Signals intelligence operations are the principal way to exploit an adversary's use of the electromagnetic spectrum.

1001. What Is Signals Intelligence?

Signals intelligence (SIGINT) is "a category o intelligence comprising either individually or in combination all communications intelligence, electronic intelligence, and foreign instrumentation signals intelligence, however transmitted" (Joint Pub 1-02). Simply, SIGINT is intelligence gained by exploiting an adversary's use of the electromagnetic spectrum with the aim of gaining undetected firsthand intelligence on the adversary's intentions, dispositions, capabilities, and limitations.

a. Communications Intelligence

Communications intelligence (COMINT) is the technical and intelligence information derived from foreign communications by anyone othe than the intended recipient.

b. Electronics Intelligence

Electronics intelligence (ELINT) is the technical and intelligence information derived from foreign noncommunication electromagnetic radiation emanating from anywhere other than nuclear detonations or radioactive sources.

c. Foreign Instrumentation Signals Intelligence

Foreign instrumentation signals intelligence (FISINT) is the technical and intelligence information derived from the intercept of foreign instrumentation signals by anyone other than the intended recipients. (FISINT is primarily strategic in nature and will not be addressed further in this manual.)

1002. Concept of Employment

SIGINT can be employed in tactical situation when the enemy uses electromagnetic spectru communications and/or systems. Optimal employment is against enemy forces that depend on tactical communications and noncommunications for command and control of their operations. SIGINT operations are more difficult against enemy forces that have established more permanent emplacements using land lines or other cabled communications systems.

SIGINT is one of several intelligence disciplines. The other key intelligence disciplines are imagery intelligence (IMINT), human resources intelligence (HUMINT), and measurement and signature intelligence (MASINT).

1003. SIGINT and Electronic Warfare

Electronic warfare (EW) is "any military action involving the use of electromagnetic and directed energy to control the electromagnetic spectrum or to attack the enemy" (Joint Pub 1-02). EW denies the enemy use of the electromagnetic spectru for command and control and protects it for friendly command and control. There are three divisions of EW.

a. Electronic Warfare Support

Electronic warfare support (ES) includes actions tasked by or under the direct control of an operational commander to search for, intercept, identify, and locate sources of intentional and unintentional radiated enemy electromagnetic signals for the purpose of *immediate* threat recognition. ES provides information required for immediate tactical decisions and operations such as the identification of imminent hostile actions, threat avoidance, targeting, or electronic attack.

Both SIGINT and ES involve searching for, intercepting, identifying, and locating electronic emitters. The primary differences between the two are the information's intended use, the degree of analytical effort expended, the detail of information provided, and the timeliness required.

SIGINT is used to gain information concerning the enemy, usually in response to a priority intelligence requirement (PIR), an intelligence requirement (IR), or other means. As described in chapter 6, SIGINT support is usually provided to the Marine air-ground task force (MAGTF) as a whole, but may also be provided directly to subordinate elements.

SIGINT information is normally provided to the MAGTF all-source fusion center (AFC) for inclusion into all-source intelligence products and for further dissemination throughout the MAGTF and to external organizations. See Marine Corps Warfighting Publication [MCWP] 2-1, *Intelligence Operations*. SIGINT-derived information of immediate tactical importance that does not require further processing, correlation, or analysi may be passed directly to subordinate commanders or to the operations section or supporting arms element of supported commands, in accordance with United States Signals Intelligence Directive (USSID) 316, *Non-Codeword Reporting Program*, and USSID 240, *ELINT Processing, Analysis, Reporting, and Forwarding Procedures*.

b. Electronic Attack

Electronic attack (EA) is action taken to prevent or reduce an enemy's effective use of the electromagnetic spectrum.

The objectives of SIGINT may conflict with those of EA. For example, EA may be conducted to interfere with the adversary's use of an emitter a the same time as SIGINT operations are designed to exploit the adversary's use of the same emitter. Furthermore, EA operations against one target may disrupt or otherwise interfere with friendly SIGINT collection against the same or differen targets.

SIGINT operations, EA operations, and the MAGTF's overall use of the electromagnetic spectrum for command and control (C2) operations must be carefully coordinated within the MAGTF and with pertinent external organizations. Depending on operational requirements, SIGINT and EA operations coordination and deconfliction may occur within the radio battalion operations control and analysis center (OCAC) within the electronic warfare coordination center (EWCC), or within the MAGTF command element (CE) current operations center (COC).

c. Electronic Protection

Electronic protection (EP) involves the action taken to ensure effective, friendly use of the electromagnetic spectrum despite the enemy's use of EW. Within the MAGTF, SIGINT elements may be tasked to employ similar techniques agains friendly force electronic emitters in order to identify and help eliminate signals security vulnerabilities that could be exploited by an enemy's SIGINT operations.

1004. Threats

a. Enemy Capabilities

The more a combat unit relies on the electromagnetic spectrum, the more vulnerable it is to the enemy's signals intelligence and electronic warfare actions. The enemy can—

- Detect a unit's devices which radiate electromagnetic energy to reveal its identity and location.
- Monitor a unit's communications to reveal its intentions, combat capabilities, logistics and personnel status, and other critical operational and tactical information.
- Inject false information into communications and information systems (CIS) to confuse and mislead a unit.
- Interrupt a unit's use of the electromagnetic spectrum, thereby degrading its ability to receive and process intelligence, plan operations, and execute C2 functions.

b. Countermeasures

To counter threats listed and to enhance effectiveness, Marines must be able to—

- Protect, to the maximum extent possible, the free use of the electromagnetic spectrum and ensure the reliable performance of ou CIS.
- Exploit the enemy's use of the electromagnetic spectrum for intelligence and targeting and intrude into the enemy's CIS and networks.
- Attack the enemy's CIS to adversely affect their decisionmaking process and operations.

1005. All-Source Intelligence and Operations Command Support

Generally, SIGINT is more useful to the commander and the decisionmaking process when has been correlated and fused with information from other intelligence sources and disseminated in easily usable, tailored, all-source intelligence products. Tactical SIGINT operations within the MAGTF, along with other services, theater, and national SIGINT support, make SIGINT a valuable source of information within the overall intelligence effort. SIGINT supports the following six functions of intelligence.

a. Commander's Estimate

SIGINT helps formulate and modify the commander's estimate of the situation by providing information needed to analyze the enemy's C2 operations, identify the current parameters of operating emitters, give insight into enemy intentions, and assess the enemy's intelligence, EW and other military capabilities.

b. Development of the Situation

SIGINT's ability to track enemy emitters and associated units and to obtain indicators of intentions can confirm or refute potential enemy courses of action. SIGINT also helps commanders to better understand the enemy and the battlespace, thereby reducing uncertainty by acquiring information regarding enemy structure, dispositions, locations, movements, and operational activities and patterns.

c. Indications and Warning

SIGINT is often the principal provider of indications and warning (I&W) because adversaries often reveal their intentions, locations, and movements in their communications and other electronic emissions.

d. Force Protection

SIGINT supports force protection by revealing critical intelligence about enemy intelligence, sabotage, subversion, and terrorism and by assessing the vulnerability of friendly C2 and CI operations.

e. Targeting

SIGINT supports targeting by providing key operational and locational intelligence on enemy C2 operations and facilities, weapons systems, force compositions, and dispositions. Information provided through SIGINT can identify high value and high payoff targets and help develop options for attacking these targets. SIGINT also supports all-source intelligence gain and loss assessments of potential enemy targets.

f. Combat Assessment

SIGINT can aid in all-source intelligence support of battle damage assessments by exploiting enemy reports of sustained battle damages and by detecting changes in enemy operations subsequen to friendly attacks.

1006. Capabilities

a. Remote Intelligence

SIGINT operations provide extended-range intelligence without the need for physical presence within or near the surveillance area. The standoff range for SIGINT operations is directly dependent on the characteristics of the terrain in which SIGINT collection is being conducted and the type, operating characteristics, and methods of employment of the enemy's electromagnetic systems. Some enemy electromagnetic systems may require that SIGINT operations be close to the transmission origin, path, or medium. Conversely, other electromagnetic systems may be exploitable from positions farther away from the transmission origin, path, or medium.

(1) Ground SIGINT Elements. Locating ground SIGINT operational elements with friendly combat forces provides the friendly commander with the capability to collect a wide range of intelligence information. Locating SIGINT element with the ground combat element (GCE) forces provides the MAGTF commander with intelligence support for decisionmaking as well as I&W and force protection intelligence reporting to the local unit.

(2) Air-Platform SIGINT Elements. Airborn SIGINT elements can provide direct support to both air and ground operations and significantly enhance collection operations by exploiting enemy targets masked or otherwise unattainable by ground-based elements. These SIGINT elements also support friendly air operations by identifying, locating, and determining the status of enemy surveillance, targeting, and weapons systems and by providing intelligence support to friendly EA operations targeting these enemy systems.

(3) Ship-Based SIGINT Elements. SIGINT elements may operate from ship-based SIGIN operations facilities in support of amphibious operations. Marine and Navy elements operating from ship-based SIGINT facilities may support amphibious operations as a part of the assault force, airborne SIGINT operations, or ship-based SIGINT operations. Within an amphibious task force (ATF), the principal SIGINT facilities are found with ship's signals exploitation spaces (SSESs) located within the intelligence centers of many ships.

b. Target Detection and Identification

SIGINT can detect enemy activity in designated areas and provide a general indication of its type and volume. Analysis of SIGINT information can provide the identity and location of specific enemy units, indications of enemy plans and future operations, and the type, function, and location of specific enemy units and systems.

c. Near-Real-Time Reporting

SIGINT operations can immediately report enemy actions or events critical to the operations of friendly units. Time-sensitive SIGINT reporting to combat units may be via standard MAGTF

intelligence communications channels or any available direct communications means.

d. Continuous Operations

SIGINT operations are conducted on a 24-hou basis. The size and composition of SIGINT forces along with the supported commander(s)'s concept of operations will influence the scope, services and capabilities of SIGINT operations.

e. Stealth

SIGINT operations are a passive intelligence technique and can usually be conducted withou the enemy's knowledge or detection. EW operations include both active and passive techniques and, depending on implementation, may or may not be recognized by the enemy.

f. Flexibility

Marine SIGINT operations may be employed in a variety of means to support the MAGTF concept of operations and supporting intelligence operations. SIGINT elements may be deployed with advance forces or forward ground units; they may be aboard air platforms or ship-based. Additionally, Marine SIGINT elements routinely operate with joint and other service elements. These elements are effective at leveraging their capabilities in support of MAGTF requirements.

1007. Limitations

a. Enemy System

The primary value of SIGINT operations is against enemy systems using electromagnetic spectrum system transmissions. SIGINT operations are ineffective against systems that do no use radio frequency (RF) transmissions (e.g., fiber optics, land-line telephone systems, or other cabled systems). If the enemy conducts operations under enemy emission control (EMCON) conditions (e.g., radio silence), SIGINT operations will not be effective.

b. Terrain Masking

Heavily wooded and urban areas reduce the susceptibility of enemy transmissions to SIGINT collection. In these areas, generally, SIGINT elements must be closer to the enemy's transmission origin or medium. Mountainous or very hilly terrain also inhibits SIGINT operations (particularly ground-based operations) by effectively blocking enemy signals from detection.

c. Complex Signals

Enemy signals that are complex or encrypted reduce the intelligence information available from the transmission. Complex signals (i.e., frequency hoppers) require special equipment for intercep and signals analysis. Encrypted signals require deciphering to reveal intelligence information. Deciphering simple encryption methods may be possible, but an enemy's use of complex encryption methods is currently beyond the scope of tactical SIGINT elements.

d. SIGINT versus Electronic Attack

SIGINT operations may be affected when enemy signals are being jammed. Prior to initiating EA jamming operations, consideration must be given to the intelligence value of the enemy's signal and the effects of its loss.

1008. Organization

Within the Marine Corps, the units responsible for the conduct of tactical SIGINT are the two radio battalions and the four Marine tactical electronic warfare squadrons.

a. Radio Battalion

The radio battalion (RadBn) provides tactical SIGINT, electronic warfare, communications security monitoring and analysis, and special communications operations in support of the MAGTF. A variety of employment concepts may be used depending upon the situation. Refer to chapter 4 for a detailed description of RadBns.

b. Marine Tactical Electronic Warfare Squadron

The Marine tactical electronic warfare squadron (VMAQ) conducts tactical electronic reconnaissance and ELINT operations in support of the MAGTF.

The VMAQ provides—

- ELINT collection operations to maintain the electronic order of battle, including identification of selected emitters and location o nonfriendly emitters.
- Threat warnings for friendly aircraft, ships, and ground units.
- Intelligence support to prevent, delay, or interrupt detection and tracking by enemy early warning, acquisition, and fire or missile control radars of aviation combat elemen (ACE) operations and Marine EA-6B tacti cal jamming aircraft in support of strike aircraft.

Refer to chapter 5 for a detailed description of the VMAQ.

1009. Command and Control

a. Radio Battalion

The RadBn (or RadBn detachment) is generally a subordinate command of, or attached to, the MAGTF CE. The MAGTF commander has operational control (OPCON) of the RadBn (or RadBn detachment).

(1) Staff Cognizance. The MAGTF commander exercises C2 over the RadBn or its detachments via the MAGTF intelligence officer. Such a relationship allows for the centralized direction and effective integration of SIGINT operations within the MAGTF's broader all-source intelligence concept of operations. RadBn's EW operations fa under the staff cognizance of the MAGTF operations officer, requiring close coordination and integration among the intelligence staff officer (G-2/S-2), operations staff officer (G-3/S-3), and communications and information systems officer (G-6/S-6) to achieve optimum employment of RadBn.

(2) Support Relationships The RadBn most typically operates in general support of the MAGTF. However, RadBn or its elements may be employed in direct support of any of the MAGTF's major support elements, i.e., GCE and ACE. In such cases, the scope of the supported commander's control over assigned RadBn elements usually is specified to ensure effective support of operations while allowing the MAGTF commander to maintain effective control of broader intelligence and SIGINT operations.

b. Marine Tactical Electronic Warfare Squadron

VMAQ or its detachments are subordinate to the ACE and under the OPCON of the ACE commander.

(1) Staff Cognizance. The ACE commander will usually exercise C2 over VMAQ via the ACE operations officer or tactical air command center (TACC). The ACE intelligence officer will exercise staff cognizance over VMAQ ELINT activities beyond that required to support EA missions.

(2) Support Relationships. VMAQ elements principally operate in direct support of ACE operations or other designated commanders (e.g., the joint force air component commander). However, ELINT acquired during VMAQ operations is capable of being used in general support of MAGTF elements and supporting intelligence operations.

1010. Operations

RadBn and VMAQ conduct both COMINT and ELINT operations to varying degrees. RadBns conduct predominantly COMINT operations; they also ensure rapid dissemination of fused ELIN and COMINT from organic or external sources to the G-2/S-2 and subordinate commanders. The VMAQ's main focus is ELINT and ES.

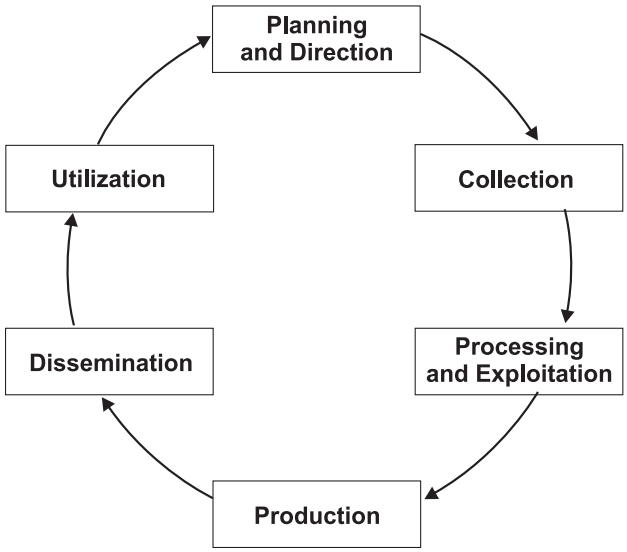

Figure 1-1. The Intelligence Cycle.

To complete intelligence tasks, RadBn an VMAQ incorporate the six intelligence cycle phases into their SIGINT methodology (see figure 1-1). Products of the SIGINT cycle are disseminated to commanders and others through the MAGTF intelligence officer. RadBn and VMAQ also provide SIGINT products to other Service and agencies as directed.

a. Planning and Direction

SIGINT direction is a continuous process that encompasses the tactical and technical employment of SIGINT assets. It begins on receipt of a warning order, initiating directive, or establishment of a planning objective and continues until termination of the mission. SIGINT unit commanders closely coordinate their operations with the MAGTF intelligence officer and pertinent external intelligence and SIGINT elements.

Planning and direction involves—

- Determining PIR and IR and SIGINT requirements to support them.
- Preparing supporting SIGINT collection, production, and dissemination plans.
- Issuing orders and requests to SIGINT units.
- Checking continuously on the productivity and effectiveness of SIGINT collectors, producers, disseminators, and other SIGINT elements and agencies.

b. Collection

During collection, organic, attached, and supporting SIGINT elements detect, collect, and record COMINT and ELINT data. The collected COMINT and ELINT data is then delivered to the appropriate SIGINT processing or production element. The OCAC is the processing and production element for RadBn, while the Tactical Electronic Reconnaissance Processing and Evaluation System (TERPES) is VMAQ's processing and production element. In some instances, such as immediate threat information, PIRs and supporting reporting criteria may direct the SIGINT collector to disseminate SIGINT reports directly to the local commander (e.g., an infantry maneuver element) for immediate support to operations.

c. Processing and Exploitation

SIGINT processing consists of converting and formatting raw signals data to a form that is usable in follow-on SIGINT and all-source intelligence analysis. The processing and exploitation phase is usually not a discrete function, but rather one that is accomplished during collection. Once the collected information has been processed, analysis must determine its significance. Other intelligence information may also be fused together with the processed SIGINT to give a comprehensive picture and to show how the information can be used by the commander to gain an advantage.

d. Production

The production stage involves converting the SIGINT analysis into appropriately tailored SIGINT reports and all-source intelligence product that can be easily understood by the commander and other users. Specifically formatted standardized messages, graphics, and other intelligence products are required to familiarize these user with layout and content and to ensure rapid usage and automated processing of finished reports. Within the MAGTF, the RadBn OCAC and the VMAQ TERPES produce SIGINT reports and products, and the MAGTF AFC incorporates

SIGINT products and information into all-source intelligence products.

e. Dissemination

Dissemination is the process through which SIGINT products are delivered to MAGTF users: the MAGTF commander, subordinate commanders and their staffs, and others as appropriate (e.g. joint force commander, joint components, and various theater and national organizations and intelligence agencies). SIGINT products are disseminated via dedicated SIGINT or general purpose CIS channels according to available CIS resources, the classification of the product, and the intelligence dissemination plan. These products include time-sensitive voice reports, text reports, data base updates, and web-based resources (e.g., via the MAGTF sensitive compartmented information local area network).

f. Utilization

SIGINT must be exploited to have value. Commanders, G-2/S-2s, G-3/S-3s, and other principal staff officers must continuously evaluate SIGINT products for timeliness, usefulness, and overa quality and provide feedback to the intelligence officer and SIGINT elements.

1011. Commanders' Responsibilities

MAGTF commanders are responsible for the planning and direction, collection, processing production, dissemination, utilization, and security of all SIGINT information by units under their command. The Director, National Security Agency (DIRNSA), delegates SIGINT operational tasking authority (SOTA) to MAGTF commanders by name for the duration of an operation o other specified period of time. SOTA allows the designated commander to task and direct the operations of organic or attached SIGINT units. Additional information regarding SOTA may be found in USSID 4, *Concept of SIGINT Support to Military Commanders*.

Commanders are also responsible for planning integrating, and using SIGINT support, if available, from other United States or allied nationa and military SIGINT organizations. The commander's primary responsibilities fall into the following areas.

a. Tasking and Directing

The commander possessing SOTA is responsible for the effective tasking and operation of assigned SIGINT assets. Generally, once a commander determines the intelligence requirements, the G-2 S-2, with the advice and assistance of the intelligence operations officer and SIGINT officer (SIO), decides which requirements can be satisfied via organic SIGINT operations. SIGINT unit commanders or officers in charge (OICs) will also coordinate operations with other key staff officers within the intelligence section (i.e., the collections manager, the AFC OIC, the surveillance and reconnaissance center OIC, and the dissemination manager). The G-2/S-2 passes these IRs as taskings to the commanding officer (CO) or OIC o the organic or attached SIGINT unit (e.g., a RadBn unit). These requirements will be in the form of either PIRs or IRs. PIRs and IRs are further managed within the intelligence effor through the use of intelligence collection requirements (ICRs), intelligence production requirements (IPRs), and intelligence dissemination requirements (IDRs) in order to achieve effective, mutually supporting all-source intelligence operations (see MCWP 2-1, chapter 3, for detailed information on IR management). The SIGINT unit commander is then responsible for commanding and controlling resources to accomplish the assigned mission. This process is discussed further in chapter 7.

b. Reporting

The ultimate goal of tactical SIGINT operations is the timely and usable production of SIGINT information which answers the MAGTF commander's PIRs and other MAGTF IRs. SIGINT reports are discussed in detail in chapter 7.

c. Protecting

The MAGTF commander is responsible for safeguarding SIGINT personnel, facilities, and information used or produced by units within the command. Loss of SIGINT units and capabilities by destruction or capture and unintended disclosures of SIGINT operations may result in severe losses of MAGTF capabilities. The effectiveness of SIGINT depends on the ability to maintain security and conceal SIGINT techniques and success from the adversary. Accordingly, the commander must provide adequate protection to prevent the capture of SIGINT facilities and personnel. In addition, special intelligence courier must be adequately protected, and positive measures must be taken to conceal courier runs and routes. To meet this responsibility, the MAGT commander must satisfy the following four basi security requirements.

(1) A special security officer (SSO) must be appointed in all units authorized to receive and use SCI. The SSO is under the staff cognizance of the unit intelligence officer and is responsible for the operation of the SCIF and the security, control, and use of SCI within the SCIF. Marine expeditionary force (MEF) CEs, Marine divisions, Marine aircraft wings, force service support groups, and other designated organizations have SSOs. Other SSOs may also be appointed as needed during tactical operations or whenever a TSCIF is established.

(2) Sensitive compartmented information (SCI generally must be handled, processed, or stored only in a SCI facility (SCIF). This may be either a mobile tactical SCIF (TSCIF) or a permanent facility. SCI security requirements are discussed in greater detail in chapter 8.

(3) Persons who handle or use SIGINT information must have proper security clearances and be indoctrinated for access to SCI and any additional required accesses. Access to SCI will be governed by need-to-know requirements. Unit commanders are responsible for determining who requires SCI access. At a minimum, all unit staff principals and key functional planners should have SCI access.

(4) SCI-secure CIS means for handling and transmitting special intelligence and SIGINT-related information must be available. These include SCI voice circuits, SCI record communications, SC local area networks (LANs), and Joint Worldwide Intelligence Communications System (JWICS).

d. Training

The MAGTF commander is responsible for ensuring that staff and operating forces are trained to effectively use SIGINT and to protect themselves against enemy SIGINT efforts.

(reverse blank)

Chapter 2

SIGINT Responsibilities in the Supporting Establishment

RadBns and VMAQs are the principal SIGINT units within the operating forces. These units are addressed further in chapters 4 and 5. To effectively execute their missions, MAGTFs, RadBns, and VMAQs draw on a wide range of external organizations to provide personnel and equipmen resources, training opportunities, and unique SIGINT support. To understand how MAGTF SIGINT operations can be supported externally, it is necessary to understand the missions and functions of external SIGINT organizations and how they provide operational support to the MAGTF.

2001. Marine Corps SIGINT Organization

a. Headquarters Marine Corps

Headquarters Marine Corps (HQMC) is responsible for the internal organization, training, equipping, and readiness of the Marine Corps; for the operation of its material support system; and for the total performance of the Marine Corps. The Assistant Chief of Staff, Command, Control, Communications, Computers, and Intelligence Department (C4I), has the following SIGINT responsibilities:

- Formulates Marine Corps SIGINT plans and policies and participates in the formulation of joint and combined plans, policies, and related command relationships.
- Determines present and future SIGINT active and reserve personnel requirements, both quantitative and qualitative.
- Provides final authority on validation and approval of all personnel augmentation from non-Fleet Marine Force (FMF) resources to support MAGTF operations.
- Reviews the internal organization, training requirements, and readiness of all SIGIN elements of the Marine Corps. The internal organization of Marine Corps SIGINT elements is constantly reviewed, with particular emphasis on occupational field (OccFld) military occupational specialty (MOS) skill requirements, to ensure requisite skills and training are available to meet MAGTF operational needs.

b. Marine Support Battalion

The Marine support battalion (MarSptBn) is a special supporting activity that provides for Marine Corps participation in national and Department of the Navy (DON) cryptologic activities. (SIGINT operations within the Navy are generally referred to as *cryptologic* operations This term may generally be used synonymously with the term *SIGINT*.) Marines in MarSptBn are assigned to national and theater organizations that support both deployed and in-garrison MAGTFs with routine and time-sensitive, mission-critica SIGINT support. Additionally, these Marines learn national-level SIGINT collection, production, and dissemination systems and benefit from SIGINT skills training available only at these sites.

(1) Commanding Officer. The principal functions and tasks assigned to the CO, MarSptBn, include the following:

- Coordinate the withdrawal of MarSptBn Marines to augment MAGTFs in response to global-sourcing requests.
- Support Marine Corps SIGINT requirements through interface at the National Security Operations Center (NSOC) and regional security operations centers

(RSOCs). (Refer to paragraph 2003 for a detailed discussion of these organizations.)

- Manage and administer the reserve SIGINT program to provide augmentation to active duty SIGINT forces.
- Provide for entry-level skills qualification and skills progression training of Marine SIGINT personnel.

(2) Battalion Headquarters. The battalion headquarters, collocated with Commander, Naval Security Group (CNSG), Fort Meade, Maryland, provides command, administrative, and Marine Corps-unique logistics support for the battalion and Marine Corps personnel in various Naval Security Group (NSG). It is under the military command and management control of the Commandant of the Marine Corps (CMC) and under the staff cognizance of the Assistant Chief of Staff, C4I, HQMC.

(3) Letter Companies. MarSptBn's letter companies support the naval mission of the Naval Security Group Activity (NSGA) to which they are assigned as well as provide for the unique service support of assigned Marines (see table 2-1). The letter companies are under the military command and administrative control of the CO, MarSptBn, while under the OPCON and technical direction of the CO of the NSGA site each supports.

(4) Company K. Company K, MarSptBn, provides administration for Marine students and staff assigned to the Naval Technological Training Center (NTTC), Pensacola, Florida, and provides liaison and instructors in conjunction with SIGINT training.

2002. SIGINT Organizations in Other Military Services

Services man, train, and equip organic SIGIN forces to support their operational commander and to prepare to participate in joint, theater, national, and combined operations. Each Service has a service cryptologic element (SCE) headquarters that provides SIGINT management, guidance, and oversight. The National Security Agency (NSA) maintains SIGINT operational control of each SCE.

Table 2-1. Marine Support Battalion Companies.

Company	Site/Host	Location
Headquarters Company	NSG	Ft. Meade, Maryland
Company A	NSGA Denver	Buckley Air National Guard Base, Aurora, Colorad
Company B	NSG	Ft. Meade, Maryland
Company D	NSGA Ft. Gordon	Ft. Gordon, Georgia
Company E	NSGA Misawa	Misawa Air Force Base (AFB), Japan
Company F[1]	NSGA Rota	Rota, Spain
Company G	NSGA Menwith Hill	Royal Air Force Menwith Hill, England
Company H	NSGA San Antonio	Kelly AFB, San Antonio, Texas
Company I	NSGA Kunia	Kunia, Hawaii
Company K	NTTC Corry Station	Pensacola, Florida
Company L	NSGA Guantanamo	Guantanamo Bay, Cuba
[1]Company F is scheduled for deactivation 30 June 1999.		

a. Naval Security Group

NSG is the DON's SCE. It directly supports deployed MAGTFs by providing access to—

- SSES use with MAGTF SIGINT personnel while embarked.
- Direct support to MAGTF operations with NSG elements operating aboard Navy ships or aircraft.
- Direct service support to MAGTF operations from ashore NSG facilities in the theater of operations.
- Hardware, software, specialized equipment, and training to the RadBns.
- SIGINT technical support kits from regionally focused cryptologic shore support activities.

b. United States Army Intelligence and Security Command

United States Army Intelligence and Security Command (INSCOM) is the Army's SCE. It provides support to deployed MAGTFs when—

- Marines are part of a joint force that includes Army SIGINT units.
- Marines are serving as part of a larger force that includes adjacent Army units.
- Army theater fixed-site activity or mobile SIGINT asset can provide support.

c. Air Intelligence Agency

Air Force Intelligence Agency (AIA) is the Ai Force's SCE. Its elements support deployed MAGTFs by collecting and producing air intelligence or by providing SIGINT support for air and air defense operations.

2003. National SIGINT Organizations

a. National Security Agency

In order to provide timely, effective SIGINT support to military commanders, NSA established several tailored support mechanisms.

(1) National Security Operations Center.

The NSOC supports JTF and MAGTF operations by providing SIGINT reporting derived from national assets. The NSOC functions as the current operations and crisis management center of the NSA to ensure that time-sensitive SIGINT needs of commanders are satisfied. The NSOC works closely with the National Military Command Center (NMCC) and other Department of Defense (DOD) I&W watch centers.

(2) Regional Security Operations Centers.

NSA established three RSOCs to enhance SIGINT support to combatant commanders at all echelons. RSOCs are regionally focused and receive inputs from multiple sources. The RSOCs are located at Fort Gordon, Georgia; San Antonio, Texas; and Kunia, Hawaii.

The following organizations are established at each RSOC:

- NSG established a cryptologic shore support activity (CSSA) staffed with Marine and Navy personnel at each RSOC. CSSAs provide direct support to naval tactical operations through interface with the RSOC. This interface allows greater tailoring of RSOC operations supporting the intelligence requirements of MAGTF operations. Principal communications connectivity to CSSAs i provided by Navy communications systems within SSES.
- INSCOM established a technical control and analysis element (TCAE) at each of the RSOC locations. CSSA Marine personne interface with TCAE personnel to provide ground-oriented intelligence information in support of the MAGTF. Communication connectivity with the TCAEs is provided generally via the Trojan Spirit II communications system organic to the RadBns or communications battalions.

b. National Reconnaissance Office

The National Reconnaissance Office (NRO) provides critical support to United States SIGINT operations. NRO's mission is to enable United States global information superiority during peace

and war. NRO is responsible for unique and innovative technology, large-scale systems engineering, development and acquisition, and operation of space reconnaissance systems and related intelligence activities to support global information superiority. NRO's capabilities include supporting I&W, monitoring arms control agreements and supporting military operations. The NRO accomplishes its mission through ongoing research and development, acquisition, and operation o spaceborne and airborne intelligence data collection systems. NRO assets and capabilities may be requested to support MAGTF operations unde procedures described in the *Joint Tactical Exploitation of National Systems (J-TENS) Manual*.

Chapter 3

SIGINT Responsibilities in the MAGTF

The MAGTF commander is ultimately responsible for the conduct of MAGTF SIGINT operations. The MAGTF commander's staff, major subordinate commands (MSCs), specialized units, and theater or national level organizations assist the commander in execution of SIGINT responsibilities. This chapter focuses on the roles and responsibilities of Marine operating forces' staffs, MSCs, and specialized units.

3001. Commanders, Marine Corps Forces

Commanders, Marine Corps forces (COMMARFORs), are responsible for using their organic SIGINT assets effectively and for ensuring responsive national and theater support to subordinate commands. COMMARFORs—

- **Review and validate SIGINT support requests from subordinate commands and ensure they receive the tailored support they require.**
- **Review and comment on cryptologic support plans (CSPs) prepared by NSA and theater combatant commanders for MAGTF operation plans (OPLANs).**
- **Coordinate SIGINT issues and requirements with the theater and national agencies in support of Marine Corps forces (MARFOR).**
- **Coordinate with theater and national SIGINT and all-source intelligence agencies and organizations to support MARFORs.**
- **Review, exercise, and if necessary, develop, interoperable CIS architectures to support the SIGINT effort.**
- **Coordinate between MARFOR and their subordinate commands to improve SIGINT interoperability, standardization, preparedness, and performance.**

3002. MAGTF Staff Sections

a. G-2/S-2

All MAGTF intelligence and counterintelligence activities, to include SIGINT, are under the staff cognizance of the unit G-2/S-2. Within the bounds of the commander's SOTA, the G-2/S-2 is responsible for planning, directing, managing, and supervising the tasking and operations of SIGINT units organic to and supporting the MAGTF. The G-2/S-2—

- **Develops and satisfies outstanding PIRs and IRs by planning, directing, integrating, and supervising organic SIGINT operations and other MAGTF all-source intelligence operations.**
- **Prepares MAGTF SIGINT plans and orders.**
- **Coordinates SIGINT collection (to include SIGINT amplifications and SIGINT time sensitive requirements), production, and dissemination requirements that are beyond the capability of the MAGTF and submits them to higher headquarters for JTF, theater, o national SIGINT support.**
- **Ensures routine and time-sensitive SIGINT information is rapidly processed, analyzed, and incorporated in all-source intelligence products, and rapidly disseminates this information to MAGTF and external units.**
- **Evaluates JTF, theater, and national SIGINT support to the MAGTF and adjusts stated requirements if necessary.**
- **Identifies, validates, and assists with resolution of SIGINT personnel and equipment resources deficiencies (e.g., insufficient linguists and special signal analysts expertise).**
- **Incorporates SIGINT in training exercises to improve MAGTF individual, collective, and unit readiness.**

b. G-1/S-1

The manpower or personnel staff officer (G-1/S-1) is responsible for all SIGINT personnel requirements. Often it is necessary to augment organic SIGINT units with specially-trained personnel from outside the command. The G-1 S-1 either internally sources or forwards personnel augmentation requests developed by the G-2/S-2 to higher headquarters for action.

c. G-3/S-3

The G-3/S-3 is responsible for planning, coordinating, and supervising the tactical employmen of units. The G-3/S-3 coordinates the movement and operations of SIGINT units with the G-2/S-2 for integration in current and future operations planning. Because SIGINT units also provide certain EW capabilities, the G-3/S-3, normally via the electronic warfare officer (EWO), coordinates SIGINT units' tactical positioning to provide tactical EW and command and control warfare (C2W) support. Normally, as the principal staf SIGINT user, the G-3/S-3 has the primary responsibility for planning maneuver operations and fire support, which requires close coordination throughout the planning process to ensure effective SIGINT support.

d. G-4/S-4

The logistics staff officer (G-4/S-4) is responsible for the combat service support (CSS) of MAGTF SIGINT units. To ensure the required support i available, the G-4/S-4 develops CSS arrangements to meet the needs of the deployed SIGINT units (particularly SIGINT units' unique equipment logistics requirements).

e. G-6/S-6

The G-6/S-6 is responsible for providing and protecting internal and external MAGTF CIS connectivity and operations. The G-6/S-6—

- Coordinates or provides communication paths, network accesses, and frequencies for SIGINT organizations attached to and/or supporting the command.
- Provides representation for CIS matters within the EWCC, when it is established.
- Assists the unit security manager and G-3/S-3 in promoting personnel awareness o enemy SIGINT threat capabilities, signals security training, and unit signals security preparedness.

3003. MAGTF Intelligence Section Elements

The MAGTF intelligence section, resident in the MAGTF CE, is the focal point for MAGTF SIGINT planning and direction and is supported by the combat intelligence center (CIC). Depending on the size of the MAGTF, operational requirements or other factors, the CIC may consist of a number of subordinate elements.

a. Combat Intelligence Center

The CIC is established within the MAGTF CE. Performing the primary functions of the MAGTF intelligence section, the CIC includes the following subelements.

(1) All-Source Fusion Center The AFC is the primary MAGTF analysis and production element. It processes and produces all-source intelligence products in response to MAGTF requirements.

(2) Surveillance and Reconnaissance Center. The surveillance and reconnaissance cente (SARC) is the primary element for the supervision of MAGTF collection operations. It directs, coordinates, and monitors intelligence collections operations conducted by organic, attached, and direct support collection assets.

(3) Operations Control and Analysis Center. The OCAC is the main node for the command and control of RadBn SIGINT operation and the overall coordination of MAGTF SIGINT operations. It processes, analyzes, produces, and disseminates SIGINT-derived information and directs the ground-based EW activities of the RadBn.

b. Intelligence Section and SIGINT Unit Commanders and Officers in Charge

(1) Intelligence Operations Officer. The intelligence operations officer is responsible to the G-2/S-2 for the overall planning and execution of MAGTF all-source intelligence operations. The intelligence operations officer—

- Plans and implements a concept of intelligence operations based upon the mission threat, commander's intent, and concept of operations.
- Develops, consolidates, validates, and prioritizes recommended PIRs and IRs to support MAGTF planning and operations.
- Plans, develops, and directs MAGTF intelligence collections, production, and dissemination plans, to include the effective employment and integration of MAGTF multidiscipline intelligence and reconnaissance operations.
- Coordinates and integrates MAGTF intelligence operations with other components, JTF, theater, and national intelligence operations.
- Evaluates and improves MAGTF intelligence operations.

(2) SIGINT Officer. The SIO is responsible to the MAGTF G-2/S-2 for the planning, direction, and execution of MAGTF SIGINT operations. The SIO—

- Coordinates with other intelligence section staff officers, the RadBn CO or OIC, and the ACE G-2/S-2 (for VMAQ TERPES operations) to prepare SIGINT plans and order for the MAGTF.
- Coordinates with the collection management officer and RadBn and VMAQ TERPES planners to coordinate, plan, supervise, and assist SIGINT collection requirement and taskings for MAGTF operations.
- Coordinates with the SARC OIC, RadBn CO or OIC, VMAQ TERPES OIC, and G-3/S-3 to coordinate the movement, operation, and reporting of SIGINT units.
- Coordinates with MAGTF AFC OIC, RadBn CO or OIC, and VMAQ TERPES OIC to coordinate MAGTF AFC analyst exchanges with RadBn TERPES COMINT and ELINT analysts and to coordinate the integration of SIGINT with all-source intelligence production.
- Coordinates with the dissemination officer to plan for the timely reporting of SIGINT-derived intelligence to MAGTF and external elements and the rapid handling of perishable SIGINT information.
- Coordinates with the G-6/S-6, Marine division (MARDIV) OICs, Marine aircraft wing (MAW) special security communications teams (SSCTs), and SIGINT unit OICs to plan and coordinate special intelligence communications paths and operations.
- Assists the intelligence operations officer with preparing and presenting special intelligence briefings and reports as required.

(3) Special Security Officer. The SSO is responsible to the commander for ensuring the command's adherence to SCI regulations and policies, security clearance procedures, and SCI materia handling. Generally, the SSO is the unit's senior intelligence officer. The SSO—

- Establishes and/or maintains a SCIF or TSCIFs to support SIGINT and other compartmented operations.
- Ensures that the command and all subordinate organizations have sufficient SCI billets to meet all potential operational requirements, to include the administration and management of unit SCI billets and SCI security investigations.
- Provides oversight, training, and supporting procedures for the conduct of SCI sanitization and dissemination within the MAGTF. This includes the determination of applicable authority for sanitization and authorized recipients of the sanitized material.

(4) Collections Management Officer. The collections management officer (CMO) is responsible for formulating detailed ICRs and tasking and coordinating internal and external collection operations to satisfy the requirements. The CMO receives PIRs and IRs from the intelligence operations officer and develops an integrated collection plan using organic and supporting resources.

In coordination with the SIO and SIGINT unit COs or OICs, the CMO—

- Determines and coordinates ICRs that may be tasked to organic or supporting SIGINT elements.
- Identifies ICRs and prepares requests for intelligence that are beyond organic capabilities and that must be submitted to higher headquarters and external agencies for satisfaction.

(5) MAGTF All-Source Fusion Center Officer in Charge. The MAGTF AFC OIC is primarily responsibile for managing and supervising the MAGTF's all-source intelligence production and processing effort. The MAGTF AFC OIC—

- Determines and coordinates MAGTF IPRs, to include SIGINT element products as well as all-source intelligence products.
- Maintains all-source automated intelligence data bases, files, workbooks, country studies, planning imagery, mapping and topographic resources, and other references.
- Administers, operates, and maintains intelligence processing and production systems both general service (GENSER) and SCI, e.g., joint deployable intelligence support system (JDISS) and intelligence analysis system (IAS).
- Analyzes and fuses all-source intelligence into tailored products in response to stated or anticipated PIRs and IRs, to include sanitized SCI products.
- Develops and maintains current and future intelligence situational, threat and environmental assessments, and target intelligence based upon all-source analysis, interpretation, and integration.

(6) Surveillance and Reconnaissance Center Officer in Charge. The SARC OIC is responsible for coordinating and supervising the execution of the integrated organic, attached and direct support intelligence collection, and reconnaissance operations. The SARC OIC—

- Maintains the status of the following ongoing intelligence collection operations, to include deployed RadBn collection and direction finding teams:
  - Mission of all teams.
  - Locations and times of all restricted fire areas and reconnaissance areas of operations.
  - Time and method of radio reconnaissance team (RRT) insertion and extraction.
  - Primary and alternate communications plans.
  - Time of last contact.
  - Time of next contact.
- Coordinates and monitors the insertion and extraction of SIGINT and other intelligence elements.
- Coordinates RadBn and VMAQ TERPES elements' collection and reporting activities under the overall intelligence operations plan. Ensures SIGINT elements understand the collection plan and are able to carry out their responsibilities under the plan.
- Ensures other MAGTF C2 nodes (e.g., the current operations center, the fire support coordination center) are apprised of ongoing intelligence and reconnaissance operations.
- Receives routine and time-sensitive intelligence reports from deployed SIGINT collection teams; cross-cues or exchanges intelligence reports with other intelligence collectors, as appropriate; and rapidly disseminates intelligence to MAGTF C2 nodes and others in accordance with intelligence reporting criteria and dissemination plans.

(7) Dissemination Officer. The dissemination officer is responsible for the effective conduct of

intelligence dissemination within the MAGTF. The dissemination officer—

- Determines and coordinates MAGTF IDRs, to include all-source IDRs as well as intelligence discipline-unique requirements.
- Recommends dissemination priorities.
- Advises on and selects dissemination means.
- Develops intelligence dissemination plans and coordinates with the G-6/S-6 supporting CIS architectures for both voice and data networked communications. Coordinates and integrates these plans and architectures with theater, joint force, and MAGTF CIS and intelligence plans and architectures.
- Monitors the flow and ensures timely delivery of intelligence throughout the MAGTF.

(8) SIGINT Unit Commanding Officer or Officer in Charge. The SIGINT unit CO or OIC is responsible for the effective conduct o SIGINT operations in support of the commander's intent and the operational and intelligence concept of operations. The SIGINT unit CO or OIC—

- Plans and employs SIGINT resources in response to the commander's intent, threat situation, MAGTF G-2/S-2's guidance a direction, and intelligence operations plan.
- Effects technical direction and control of MAGTF organic SIGINT collection, processing and exploitation, production, and dissemination operations. Also helps coordinate MAGTF SIGINT operations with JTF, theater, national, and other Service SIGINT agencies.
- Coordinates movement and operations of SIGINT units with MAGTF staff element and subordinate units' commanders. Ensures that all element movements are coordinated with the COC, fire support coordination center (FSCC), and SARC.
- Advises the G-2/S-2, SIO, intelligence operations officer, MAGTF AFC OIC, CMO, and dissemination officer on SIGINT employment and its integration with JTF, theater, and national SIGINT operations.

3004. Marine Divisions and Aircraft Wings

SIGINT activities of the MARDIVs and MAWs come under the staff cognizance of the respective G-2s. This includes the integration of SIGINT operations and products in support of unit operations and the operations of their organic SSCT. SSCTs provide special intelligence (SI) communications support to their commanders and designated subordinate elements.

3005. Radio Battalions

The 1st and 2d RadBns are the Marine Corps' principal organic, tactical, SIGINT direct support elements. The primary mission of the RadBn and its detachments is to provide tactical SIGINT support to MAGTFs. RadBns are discussed further in chapter 4.

3006. VMAQs

VMAQs of Marine aircraft group (MAG)-14 perform airborne electronic reconnaissance and, through the use of TERPES, produce ELINT reports and electronic order of battle (EOB) intelligence. Due to the unique capabilities of TERPES, the ACE will often be tasked with producing and maintaining the EOB to be used by all MAGT elements. VMAQs are discussed in chapter 5.

(reverse blank)

CHAPTER 4

Radio Battalion

The mission of radio battalions is to provide communications security (COMSEC) monitoring, tactical SIGINT, EW, and SI communication support to the MAGTF.

4001. Tasks

The radio battalion—

- **Conducts interception, radio direction finding (DF), recording, and analysis of communications and noncommunications signals and SIGINT processing, analysis, production, and reporting.**
- **Conducts EW against enemy or other hostile communications.**
- **Assists in the protection of MAGTF communications from enemy exploitation by conducting COMSEC monitoring, analysis, and reporting on friendly force communications.**
- **Provides SI communications support and cryptographic guard (personnel and terminal equipment) in support of MAGTF command elements and RadBn operations. (Normally, communications connectivity for SI communications is provided by the communications unit supporting the MAGTF CE.)**
- **Provides task-organized detachments to MAGTFs with designated SIGINT, EW, SI communications, and other required capabilities.**
- **Exercises technical control and direction over MAGTF RadBn SIGINT and EW operations.**
- **Provides RRT with specialized insertion and extraction capabilities (e.g., combat rubber raiding craft, fast rope, rappel, helocast, static line parachute) to provide specified SIGINT and EA support during advance force, preassault, or deep postassault operations.**
- **Coordinates technical SIGINT requirements and exchanges SIGINT technical information and material with national, theater, joint, and other SIGINT units.**
- **Provides intermediate, third- and fourth-echelon maintenance of RadBn SIGINT and EW equipment.**

4002. Organization

The 1st RadBn, Marine Corps Base (MCB), Kaneohe Bay, Hawaii, is subordinate to Commander, Marine Corps Forces, Pacific (COMMARFORPAC), and supports both I and III MEFs. The 2d RadBn, Camp Lejeune, North Carolina, is subordinate to II MEF. Both battalions are organized and equipped along functional lines to provide administrative control of subordinate elements, to facilitate training, and to permit rapid structuring and operational deployment o task-organized units or detachments.

The 1st RadBn is organized into a headquarter and service (H&S) company and three line companies (A, B, and C). The 2d RadBn is comprised of an H&S company and two line companies (A and B). See figure 4-1 on page 4-2. RadBns' line companies are not tactical organizations, but instead they serve as training and administrative units providing the basic unit structure around which task-organized SIGINT support units o detachments are trained, equipped, and formed Even if the entire RadBn were to deploy, it would task-organize for the mission assigned.

a. Headquarters and Service Company

The H&S company provides personnel and facilities with which the RadBn commander commands and controls battalion operations. It also provides service support for other battalion

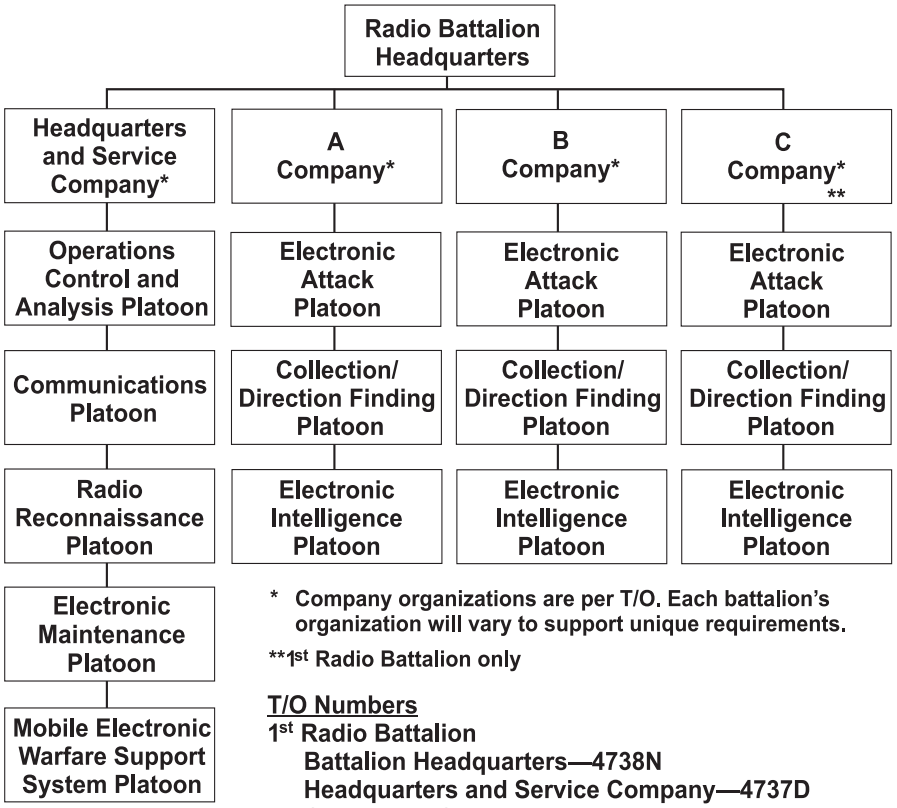

Figure 4-1. Radio Battalion Organization.

elements. Those tasks are accomplished by H&S staff sections (i.e., S-1, S-2, S-3, S-4, and S-6) and the following specialized platoons.

(1) Operations Control and Analysis Platoon. The operations control and analysis (OCA) platoon provides the Marines and equipment to perform RadBn operational planning and direction and SIGINT production, analysis, and reporting operations. Additionally, it is the nucleus for the RadBn OCAC during tactical operations.

(2) Communications Platoon. The communications platoon provides Marines and equipment to conduct special security communications operations in support of RadBn and, when deployed, MAGTF CE operations. Additionally, the platoon is equipped to support RadBn's internal communications requirements.

(3) Radio Reconnaissance Platoon. The radio reconnaissance platoon (RRP) provides trained RRTs for operations during advance force, preassault, or other operations where the employment of conventional RadBn teams may be inappropriate or unfeasible.

(4) Electronic Maintenance Platoon. The electronic maintenance platoon provides up to fourth-echelon maintenance support on RadBn unique equipment and second-echelon support on Marine Corps common communications and electronics equipment.

(5) Mobile Electronic Warfare Support System Platoon. Using a light armored vehicle (LAV) variant platform, the mobile electronic warfare support system (MEWSS) platoon provides Marines and equipment capable of SIGINT

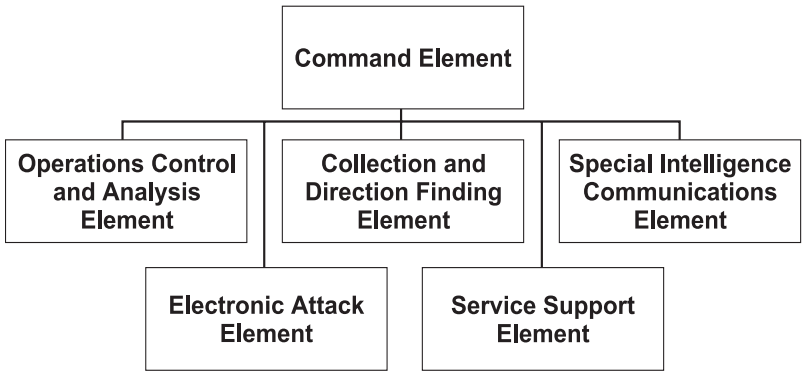

Figure 4-2. SIGINT Support Unit Elements.

collection, DF, reporting, and communication jamming operations.

b. Operational Companies

Each RadBn operational company has a table of organization (T/O) of 5 officers and 100 enlisted Marines organized into a company headquarters, EA platoon, voice collection and DF platoon, and nonvoice or ELINT collection platoon. During tactical operations, the company will be task-organized or reinforced with battalion assets consistent with the threat, mission, commander's intent, and intelligence concept of operations.

4003. Task Organization for MAGTF Operations SIGINT Support Unit

An entire RadBn will support a MEF operation To support smaller MAGTFs, the RadBn's tactical organization is the task-organized SIGINT support unit (SSU). The SSU may be as large as an operational company (minus or reinforced) or as small as a four-Marine team. The RadBn organization enables the rapid structuring and operational deployment of task-organized SSUs.

a. SIGINT Support Unit Structure

A fully structured SSU containing all the capabilities found in the RadBn is comprised of six basic elements (see figure 4-2). The nature of the threat, specific mission tasking, and intelligence and operational requirements determine the composition and equipment of each element.

(1) Command Element. The RadBn CO w designate an OIC and/or a staff noncommissioned officer in charge (SNCOIC) for each SSU. The command element is comprised of the personnel and facilities to command and control the SSU For smaller SSUs, the command element may be integrated within the operations control and analysis element with an OIC or an operations officer, noncommissioned officer in charge or an operations chief, and sufficient resources for command and control of the SSU operations. When the majority of the battalion deploys, the command element consists of the battalion commander, executive officer, sergeant major, and sufficien personnel for command and administrative support.

(2) Operations Control and Analysis Element. The SSU's command and control, analysis, production, and dissemination functions are executed within the OCAC. The OCAC performs the SIGINT processing, analysis, exploitation, production, and reporting of signals intelligence products and information. Additionally, it is the principle element that coordinates with other intelligence nodes to plan, direct, and integrate SIGINT operations with other intelligence and reconnaissance operations. Marines assigned to this element include the operations watch officers or operations watch chiefs, COMINT and ELIN analysts, translators or transcribers, and SIGINT report writers.

(3) Collection and Direction Finding Element. The collection and DF element is comprised of SIGINT support teams (SSTs) and other collection elements consisting of Marines and equipment for conducting SSU SIGINT collection and DF operations. Personnel assigned to this element include SIGINT linguists (or voice intercept operators), manual-Morse, non-Morse, and ELINT collection and DF operators, and supervisory personnel. Additionally, this element may contain MEWSS- or RRT-capable SSTs if the mission or situation warrants.

(4) Electronic Attack Element. The EA element is comprised of the Marines and equipment to conduct EA operations. Personnel assigned to this element include EA supervisors or controllers and EA operators.

(5) Special Intelligence Communications Element. The SI communications element installs and operates the SI or special security communications terminals for the SSU and the MAGTF CE. In addition, the SI communications element will install and operate SCI-level LAN systems to support SSU operations. The systems installed will depend on the mission, intelligence and CIS operations concepts, connectivity requirements, and terminal equipment availability. Personnel assigned to this element include communications supervisory personnel, information systems security and system administrators, and communications operators.

(6) Service Support Element. The service support element provides limited supply, engineers, electronic maintenance, and medical support to the SSU. The SSU depends on the MAGTF combat service support element (CSSE) for most of its combat service support. Marine assigned to the service support element may include medical, electronic maintenance, motor transport, engineer, supply, and administrative personnel.

b. SIGINT Support Unit Task-Organizational Considerations

SSUs are task-organized from resources available throughout the RadBn and are tailored to the requirements of the supported commander. The SSU's specific size and composition will also be influenced by threat and environmental factors known or expected to be encountered in the intended area of operations. The following factors must be considered when task-organizing an SSU.

(1) Enemy Signals Environment. The prime factor in determining the size, composition, and capabilities of an SSU is the known or anticipated enemy signals environment. Enemy factors to consider are—

- Target power output and frequency range.
- Digital or analog signals.
- Modulation techniques.
- Target signal operating instructions (i.e., sophisticated or complex).
- Target emitters (i.e., number, type, and density).

(2) Physical Environment. Terrain, climate, vegetation, and the operations area size influence the size and composition of the SSU.

(3) Operational Environment. Among factors that must be considered are—

- The military and political situation.
- The adversary's—
  - Size.
  - Composition.
  - Disposition.
  - C2 and CIS operations.
  - Doctrine, tactics, techniques, and procedures.

c. SIGINT Support Unit Operations Watch Structure

The SSU must be capable of sustained, 24-hou operations. SSU elements, excepting the service

support element, are normally employed in two or three watch sections. In large SSUs, each watch section may have an officer and/or a staff noncommissioned officer (SNCO) assigned as an operations watch officer (OWO) or operations watch chief (OWC). In smaller SSUs, this function may be performed by a noncommissioned officer (NCO).

4004. Command and Control

a. Command Relationships

(1) Operational Control. The MAGTF commander with SOTA has OPCON of RadBn, which is exercised by the MAGTF G-2/S-2 and executed by the RadBn OIC.

(2) Administrative Control. Administrative control (ADCON) of RadBn SSUs is exercised by the unit to which the SSU is attached (in most cases the MAGTF CE).

(3) SIGINT Technical Control. SIGINT technical control (TECHCON) of United States SIGINT system assets, to include RadBn SSUs, is always retained by DIRNSA who delegates SOTA to MAGTF commanders. This means that within the MAGTF, the MAGTF commander with SOTA generally retains, coordinates, and exercises SIGINT TECHCON regardless of any other C2 relationships established for the operation (e.g., RadBn elements attached to or placed in direct support of MAGTF subordinate elements).

b. Support Relationships

The MAGTF commander may establish variou support relationships between the SSU and MAGTF subordinate elements when one organization should aid, protect, complement, or sustain another unit. The nature of the support relationship will be specified by a directive (e.g., annex B of the operations order) which should detail—

- Forces and other resources allocated to the subordinate element of the SSU.
- Time, place, level, and duration of the SSU support effort.
- Priority of the SSU supporting effort.
- Command relationships and degree of authority granted to the supported commander.

The two most common support relationships fo SSUs are general and direct support.

(1) General Support General support (GS) is action given to the MAGTF as a whole rather than to a particular subordinate element. Given the nature of SIGINT operations, GS is the most com mon support relationship used for SSU operations.

(2) Direct Support. Direct support (DS) is a mission requiring a force to support another specific force and authorizing it to answer directly the supported force's requests for assistance. When required by the mission and situation, elements of a SSU may be placed in DS of MAGTF subordinate elements (e.g., elements of the SSU in DS of the GCE).

4005. Notional Concepts of Employment and Task Organizations

The mission, enemy or other potentially hostile elements, and operational environment will always influence the composition and employment of SIGINT assets, as will logistics concerns such as footprint or airlift availability. To serve as a planning departure point, RadBns have developed notional SSU packages and concepts of employment which will be refined as mission and adversary details become known. (Appendix A, Radio Battalion SIGINT Support Unit Checklist, is provided as an SSU operations planning guide.) The levels of RadBn support can range from electronic collocation with the supported unit to an entire RadBn (minus or reinforced) deploying with a MEF as indicated by the following examples. It is important to note that no specific RadBn SSU may ever match exactly the following notional descriptions due to task organization, personnel or

equipment availability, and mission and threat considerations.

a. Marine Expeditionary Unit (Special Operations Capable) SIGINT Support Unit

The SSU concept of employment is dependent on the Marine expeditionary unit's (MEU) mission, threat, and planned concept of operations. The SSU is attached to the CE and almost always is employed in general support of the MEU (special operations capable [SOC]).

Generally, MEU(SOC) SSUs consist of 1 officer as the OIC, possibly another officer as the assistant OIC, and 20 or more enlisted Marines (to normally include at least one RRT). Table 4-1 provides a notional MEU(SOC) SSU T/O.

b. Fly-In Echelon

The fly-in echelon (FIE) is integrated and task organized to provide immediate SIGINT, EW, and SI communications in support of lead elements of a MAGTF or to reinforce MEU(SOC SSU capabilities. The FIE serves as the foundation for the buildup of SIGINT assets as required. Figure 4-3 illustrates a notional FIE configuration. The FIE generally consists of 2 officers and 18 to 30 enlisted Marines. Table 4-2 provides a typical FIE T/O. The FIE is under the operational control of the MAGTF commander who exercises SOTA. Initial operations will be in general support of MAGTF requirements. As the situation matures and the mission and associated tasks become clearer, the task organization and command relationships of the FIE or SSU elements may be modified to provide direct support to designated major subordinate elements (MSEs).

c. Marine Expeditionary Force Support

For detailed SIGINT support information regarding a specific MEF operation, refer to the CSP and annex B of the OPLAN for that operation The following is a discussion of RadBn support of a notional MEF operation.

(1) Concept of Operations A MEF-level operation is supported by the RadBn (minus or reinforced. It could be minus because prior committed RadBn assets, such as MEU SSUs, were unavailable. It could be reinforced because some level of personnel or equipment augmentation from the other RadBn, MarSptBn, and/or Marine Corps units might be required.

(2) Concept of Employment. The RadBn task-organizes and employs its companies and teams to best support the MEF by—

- Deploying collection or DF teams for improved target signals access and operational support to forward MAGTF units.
- Collocating RadBn's C2 node with the MAGTF G-2/S-2's CIC and operating within the integrated intelligence concept of operations in GS of the MAGTF.
- Focusing on tasked PIRs and IRs and providing required support to all six intelligence functions.
- Disseminating time-sensitive SIGINT products to subordinate MAGTF units when required by the tactical situation.
- Providing OCAC liaison teams (OLTs) to the lead elements of the MEF, its MSEs and adjacent units as required; and providing SIGINT support elements (SSEs) and SSTs with mobile MAGTF units.
- Providing security and CIS for all internal RadBn requirements and for specified MAGTF CE support.
- Integrating operations with other MAGTF intelligence units to support cueing of other intelligence and reconnaissance collection elements, all-source intelligence production, and other mutual support.

(3) Company Command Element. One of the keys to effective MEF support is the placemen and use of the company command elements (CCEs). The CCEs are normally collocated with the GCE or MAGTF-subordinate task force headquarters depending on the mission and threat. The CCE—

- Provides I&W support to the supported commanders.
- Coordinates location, operations, and support of SSTs with supported units and other forward-deployed intelligence and reconnaissance units.
- Serves as the C2, communications, and SIGINT-tasking channel between the OCAC and forward-deployed SST as required.
- Provides company liaison teams (CLTs) to adjacent and subordinate units as required.
- Provides or arranges for SST administration, logistic, and physical security support.
- Provides SIGINT tasking and direction of SSTs when the OCAC is unable to provide tasking and direction.

d. Radio Reconnaissance Teams

RRTs are six-Marine teams trained in special insert or extract means and basic amphibious reconnaissance capabilities. This additional training makes the RRT capable of advance force, preassault, deep postassault, and maritime special purpose force (MSPF) SIGINT missions as assigned. RRTs support the six intelligence functions. Additionally, they may be tasked to conduct SIGINT signals search and data base development in order to enhance understanding of threat operations prior to the arrival of other SSU forces. In an advance force role, RRTs may be employed to—

- Provide SIGINT-derived I&W intelligence support to advance forces.
- Provide SIGINT collection and reporting in areas not accessible to conventional SSTs.
- Provide SIGINT collection and reporting in support of assault and landing forces.
- Provide collection of unique signals. Unique signals are signals expected to have intelligence value that cannot be collected by other reasonable means (e.g., low-powered UHF communications).
- Conduct threat signals search and data base development.

e. Mobile Electronic Warfare Support System SIGINT Support Team

The principal advantage of a MEWSS SST is its high mobility, light armored protection, allowing it to maintain operations and provide direct support of similarly equipped ground combat element units. The employment of MEWSS vehicles requires close coordination with both the G-2/S-2 and G-3/S-3 as the MEWSS provides the only ground-based ELINT collection and the major ground-based communications EA capabilities organic to the MAGTF. The COMINT capabilities of the MEWSS are similar to that of any SST.

f. Aviation SIGINT Support Team

The aviation SSTs capabilities are similar to those of other SSTs. Its principal advantage is the ability to operate aboard Marine aviation platforms (e.g., helicopters). Aviation SSTs can provide SIGINT support to air and airborne units during missions such as deep raids and tactical recovery of aircraft and personnel operations or when the MAGTF commander needs immediate I&W accessible only by airborne SIGINT collection elements. The use of airborne SIGINT operation provides supporting SSTs with the ability to collect and exploit threat signals from extended ranges. The basic aviation SST is task-organized consistent with the mission and supported force's requirements. Generally, an aviation SST consists of RadBn Marines with a COMINT receiver, intelligence broadcast receiver, communications jammer, and UHF satellite communications radio.

g. Operations Control and Analysis Center Liaison Team

An OLT supports the intelligence effort of MAGTF subordinate elements (e.g., ACE or CSSE headquarters or rear area operations center). OLTs collocate with the G-2/S-2 of the supported unit operating from within its TSCIF. The OLT is task-organized out of available SSU assets in tactical support of the organization to which it is assigned. This assignment could be for a specific operation, phase, or for the duration of a conflict. Primarily, OLTs provide additional SIGINT C2 support and CIS connectivity for tactical SIGINT planning, production, and reporting with the MAGTF G-2/S-2 and RadBn OCAC. OLTs expedite, simplify, and coordinate the sharing of SIGINT I&W, technical data, taskings, and products. Normally, the OLT monitors RadBn collection teams and theater SIGINT reporting communications to provide the supported unit access to tactical and operational-level SIGINT and I&W intelligence. In most cases, an OLT will consists of at least one officer and three enlisted Marines with supporting CIS equipment.

h. Company Liaison Team

A CLT is task-organized with available assets to best satisfy the requirements of the organization or unit to which it is assigned (e.g., an infantry battalion). This assignment is normally for a specific duration or operational phase. In most cases, a CLT will consist of one SNCO and one to three additional enlisted Marines. Like the OLT, the CLT expedites SIGINT I&W to local decision-makers and assists with SST employment, tasking, and support.

i. Augmentation and Composition

Due to the low density of many SIGINT skills and equipment and the high tempo of operations, the RadBns may lack sufficient personnel with the requisite skills or SIGINT equipment with the necessary capabilities for a particular operation RadBns are reinforced with personnel and SIGINT equipment by augmenting and compositing.

For a small number of personnel requirements, individual augmentation often works best. With concurrence from the supported organization, the RadBn will forward a request for SIGINT personnel augmentation to CMC (C4I or CIS) via the COMMARFOR (G-1/G-2). Once the request is received at CMC, it will be validated and forwarded to CNSG and MarSptBn. MarSptBn will attempt to satisfy the request with active and/o reserve Marines from the battalion. Any portion of the request that MarSptBn can not satisfy will be returned to CMC (C4I/CIS) for sourcing from other Marine Corps units or other sources.

For significant numbers of personnel and equipment in support of a large operation or major regional contingency, elements may be composited from one RadBn with the other RadBn. Coordination between the RadBns should be continuous in the development of contingency plans (CONPLANs), OPLANs, and CSPs to ensure mutual understanding and validation of requirements and information (e.g., time-phased force deployment data).

Chapter 5

Marine Tactical Electronic Warfare Squadrons

Marine aviation performs six functions: offensive air support (OAS), antiair warfare (AAW), assault support, aerial reconnaissance, EW, and C2 of aircraft and missiles. VMAQs provide the MAGTF and other designated forces with EW support. The VMAQ also has an inherent capability to perform visual and electronic air reconnaissance. Electronic reconnaissance is the detection, identification, evaluation, and location of foreign electromagnetic radiation to provide EOB information. This chapter will focus on the VMAQ electronic reconnaissance and ELINT capabilities.

5001. Mission and Tasks

VMAQs provide EW (principally EA) and ELINT support to the MAGTF and other designated forces. When deployed, the VMAQ is under the operational and administrative control of the ACE commander. To support the MAGTF, the VMAQ conducts tactical jamming to prevent, delay, or interrupt detection and tracking by enemy early warning, acquisition, fire or missile control, counterbattery, and battlefield surveillance radars. Tactical jamming also denies and/or degrades enemy communications capabilities.

In addition, the VMAQ conducts electronic reconnaissance and ELINT operations to maintain EOB, to include both selected emitter parameters and location of nonfriendly emitters. VMAQs also provide threat warnings for friendly aircraft, ships, and ground units.

Key VMAQ tasks include—

- Providing aerial EA and ES support to ACE and other designated operations.
- Processing, analyzing, and producing routine and time-sensitive ELINT reports fo updating and maintaining enemy EOB. This is accomplished through the intelligence and electronic warfare division, TERPES, and the tactical EA-6B mission planning system (TEAMS) sections to support premission planning and postmission processing of collected data and production of pertinent intelligence reports. Working in concert with the intelligence section, TERPES and TEAMS sections provide required ELINT and EOB intelligence products to the ACE and MAGTF.
- Providing liaison personnel to ACE and MAGTF CE staffs to assist in VMAQ employment planning. Inherent in this task i the requirement to provide an air EW liaison officer to the MAGTF EWCC.
- Conducting EA operations for EP training of MAGTF units.
- Intercepting, recording, and jamming threat communications and noncommunication emitters.

5002. Organization and Concept of Employment

There are four VMAQs (designated VMAQ-1 through VMAQ-4) assigned to MAG-14, 2d MAW, Cherry Point, North Carolina. Each squadron has five EA-6B Prowler aircraft and is organized into administrative, intelligence and electronic warfare, operations, logistics, safety and standardization, and maintenance divisions See figures 5-1 and 5-2 on page 5-2.

EA-6B aircraft conduct EA, ELINT, and electronic reconnaissance operations in support of ACE and other MAGTF missions. The TERPES section functions as a key element of the MAGTF's intelligence operations. TERPES is an

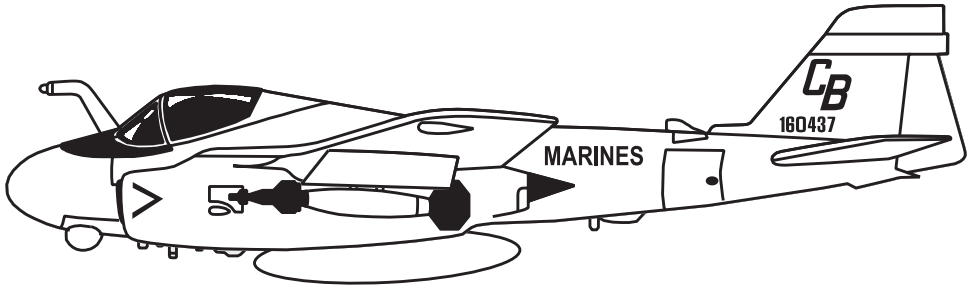

Figure 5-1. EA-6B Prowler

air-transportable, land-mobile intelligence processing and production system organic to VMAQ and is used to develop, maintain, and distribute tactical EOB and ELINT reports. TERPES functions as an automated tactical data system capable of producing current and future intelligence through information storage and retrieval, data recording, data base management, and data comparison. TERPES has a stand-alone capability but is utilized by VMAQs to optimize signals analysi and reporting to support MAGTF operations. Figure 5-3 provides an overview of VMAQ and TERPES operations.

5003. EA-6B Prowler

The EA-6B Prowler is a subsonic, all-weather, carrier-capable aircraft. The crew is composed of one pilot and three electronic countermeasure officers. The Prowler's primary missions include collecting and processing designated threat SO for jamming and subsequent processing, analysis, and intelligence reporting; and employing the AGM-88 high-speed antiradiation missile (HARM) against designated targets. The AN/ALQ-99 Tactical Jamming System effectively

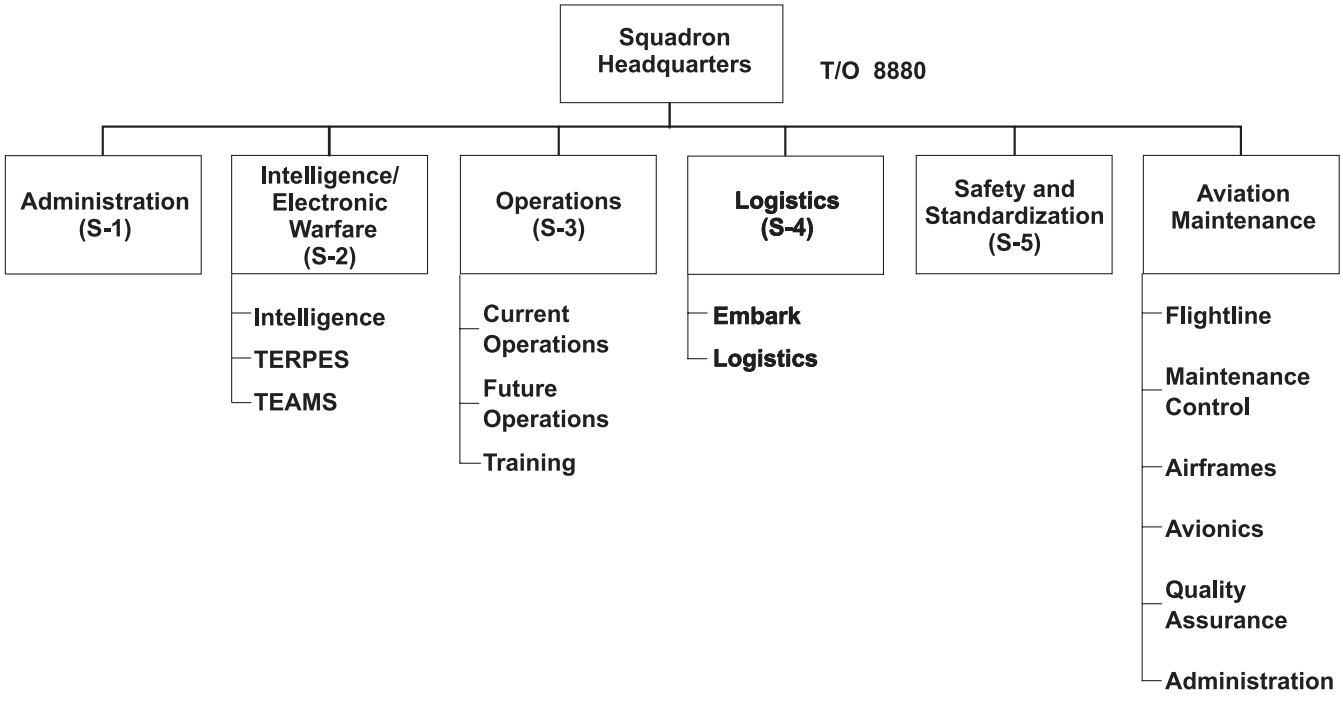

Figure 5-2. VMAQ Organization.

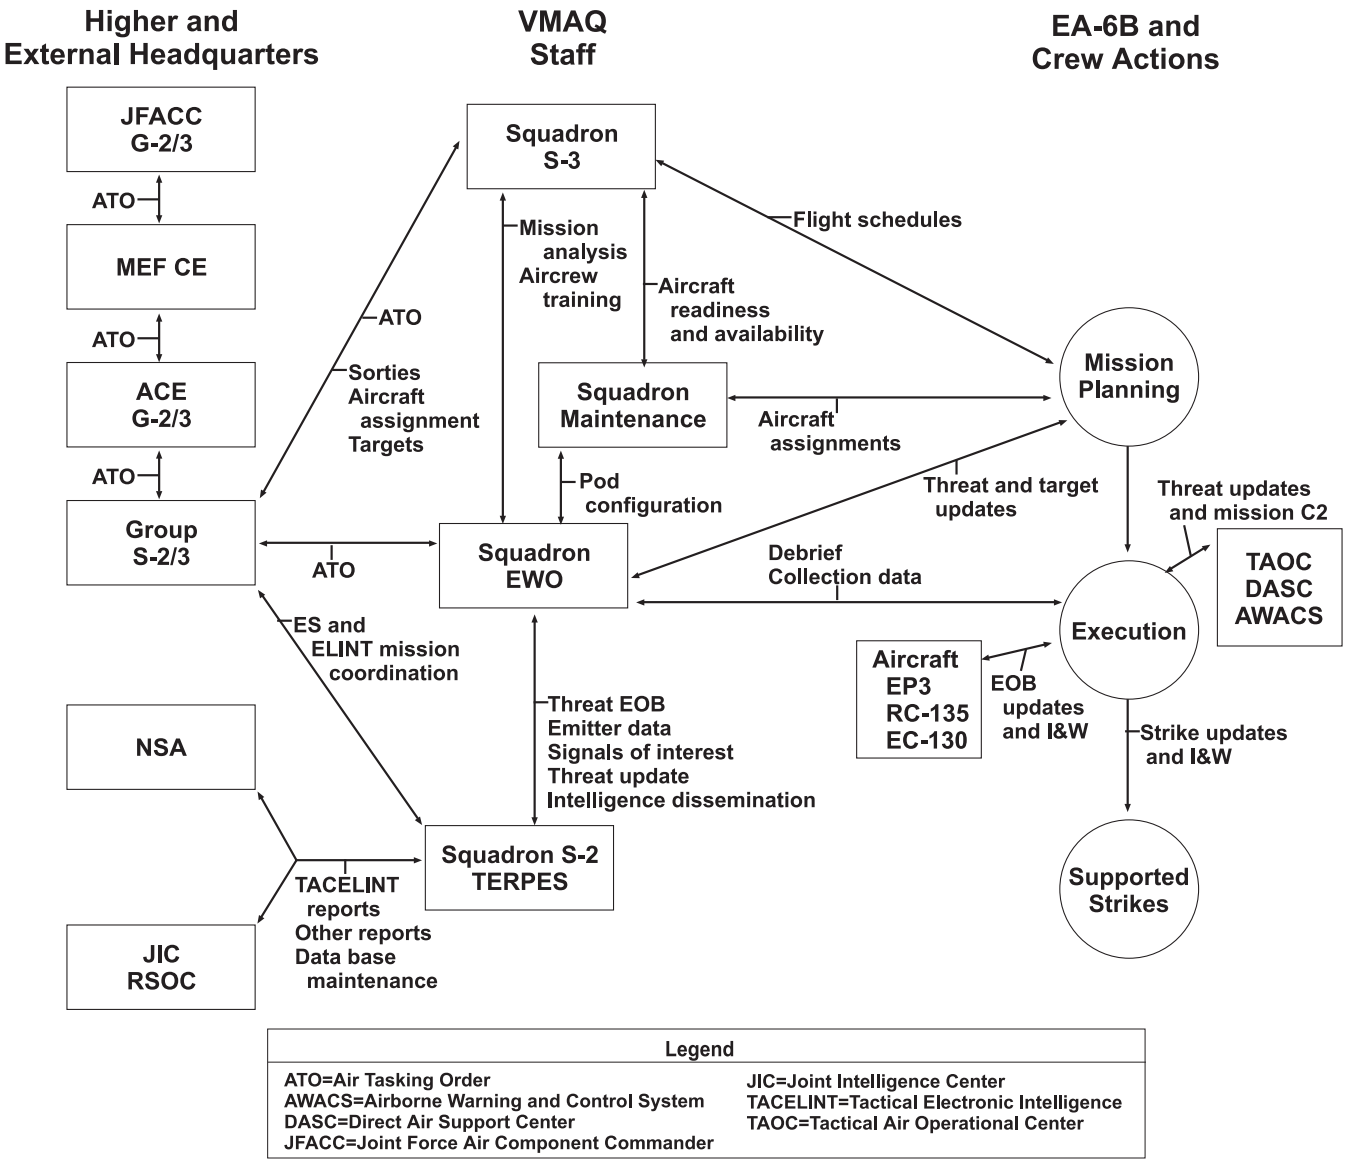

Figure 5-3. VMAQ and TERPES Operations.

incorporates receivers and external pods for signals reception and transmission of jamming signals (principally those associated with threat air defense radars and associated C2).

In addition to the AN/ALQ-99, the EA-6B also employs the USQ-113 Communications Suite which provides the ability to collect, record, and disrupt threat communications in either of the following two modes of operation:

- EA which scans the electromagnetic environment to intercept and jam targeted signals of interest (SOIs).
- ES which scans the electromagnetic environment to intercept and digitally record SOIs.

5004. Tactical EA-6B Mission Planning System

TEAMS is designed to assist EA-6B aircrew with planning allocation and optimization of receivers, jammers, HARM, and other integrated weapon systems into a comprehensive C2W package. Basic intelligence data is provided by various MAGTF theater and other intelligence and analysis centers. Parametric data for friendly and adversary platforms, weapons systems, and emitters is provided by the electronic warfare data base system (EWDS) on a quarterly basis and near-real-time updates may be provided through tactical receive equipment (TRE) integrated by the TERPES section into the TEAMS workstation. World maps, terrain data, and digitized navigation charts are provided by the National Imagery and Mapping Agency (NIMA) on a quarterly basis.

TEAMS allows the operator to—

- Maintain area of operations emitter listings.
- Edit emitter parameters.
- Develop mission-specific geographic data and EOB.
- Perform postflight mission analysis to—
  - Identify electronic emitters using various electronic parameter data bases and ELINT analytical techniques.
  - Locate emitters by coordinates with a certain circular error of probability for each site.
  - Correlate new information with existing data.
- Accomplish mission planning in support of coordinated strikes and EA-6B optimization.

5005. TERPES

TERPES (AN/TSQ-90) is an air- and land-transportable, single-shelter ELINT processing and correlation system. The TERPES team is composed of Marines, equipment, software, and supporting procedures integrated to—

- Identify and locate enemy radar emitters from data collected by EA-6B aircraft o those received from other intelligence sources.
- Process and disseminate EW data rapidly to MAGTF intelligence centers.
- Provide mission planning and briefing support to VMAQ EA and ES operations.

The standard TERPES configuration consists o one 8- by 8- by 20-foot shelter and two skid-mounted environmental control units (ECUs). Positioned on and around the shelters are a TRE antenna, an HF antenna, and two mast-mounted UHF antennas. These modules can be tailored to specific mission requirements. Electrical powe support for TERPES must be obtained from the Marine wing support squadron.

The TERPES is operated by one MOS 2602 SIGINT/EW warrant officer and six MOS 2631 TERPES operators/analysts. Maintenance support i provided by one MOS 9966 TSQ-90 maintenance officer and four MOS 2821 TSQ-90 technicians.

a. Operational Capabilities

The TERPES will—

- Translate rapidly the machine-readable, airborne-collected digital data into man- and machine-readable reports (i.e., paper, magnetic tape, secure voice, plots, and overlays).
- Receive and process EA-6B mission tapes.
- Accept, correlate, and identify electronic emitters data from semiautomatic or automatic collection systems using various electronic parameter data bases and ELINT analytical techniques.
- Locate emitters by coordinates with a certain circular error of probability for each site.

- Provide EA-6B EWOs with tactical intelligence briefings to support EA and ES missions. (The official title for EWO is electronic countermeasures officer [ECMO]. EWO is used to accurately reflect the scope of MOS 7588 activities and EW terminology changes.)
- Provide tactical jamming analysis.
- Ensure tactical intelligence data base maintenance for the VMAQ and the EOB for the MAGTF.

b. Mapping Package

The TERPES mapping and overlay package is based on NIMA products which have been integrated into a software program called the Delorme mapping system. This system allows TERPES operators to display mapping data that is loaded to the TERPES system at scales ranging from worldwide scale down to the 1:5,000 scale. A wide range of tools such as zoom, projection magnification, perspective, linear, and spatial analysis allow operators to manipulate mapping data to enhance understanding of the overlaid threat information.

c. Intelligence Analysis

The TERPES Intelligence Analysis Application (IAA) enables the operator to analyze ELINT data combined with additional modernized integrated data base (MIDB) intelligence data to—

- Respond to requests for intelligence (RFIs).
- Prepare intelligence data base updates.
- Analyze threat and tactical situations.
- Estimate changes in the threat's tactical situation.

d. Data Fusion

MIDB is the primary intelligence data base for IAA operator queries. In addition to EA-6B aircraft mission tapes, other inputs required to maximize the support provided to tactical intelligence operations include the following:

- Naval intelligence data base (NID) contains characteristics and performance data for weapons, sensors, and platforms.
- EWDS is similar to the NID and provides EA-6B tailored data.
- ELINT parameters list (EPL) is NSA's observed radar parametric data.
- Electronic warfare integrated reprogramming (EWIR) is produced by the United States Air Force Foreign Technology Division. EWIR combines assessed technical radar parameters from the United States Air Force EW Science and Technology data base with the observed parameters of the NSA data base.
- Joint spectrum center (JSC) is used to derive friendly EOB and radar parametric data.

e. TERPES Fusion Processor

The TERPES fusion processor (TFP) processe intelligence data from tactical ELINT (TACELINT) reports, tactical reports (TACREPs), and IMINT reports. The TFP provides filtering, characteristic and performance identification, order of battle (OOB) identification, technical analysis, multisource correlation, and candidate updates. The TFP presents the information in various forms for analysis. One TFP integrated information source is the TRE and Related Applications (TRAP) broadcast. This broadcast is accessed using the TRE and provides near-real-time (NRT), national-level reports to the TERPES. The TRAP broadcast also assists the TFP in maintaining an ELINT parameter data base to track airborne, shipboard, and land-based targets as a tool to develop EOBs and as an instrument to perform comparative studies on radar parameters.

f. TERPES ELINT Preprocessor

The TERPES ELINT preprocessor (TEPP) processes all EA-6B SOI collected from recorder o reproducer set tape or disk files. Specifically, the application allows for the NRT analysis of technical ELINT data. Position reports and specific unit identification and location information are used to

update the TERPES data base and to prepare TACELINT reports. TERPES also provides tactical jamming system (TJS) analysis for the EA-6B aircrew and maintenance personnel.

TJS analysis consists of recovering recorded data for verifying jammer calibration, on- and off-jammer times, and frequency and azimuth coverage. TERPES will use mission data in the generation of EW mission summary reports.

g. Intelligence Reporting

The primary intelligence output from TERPES operations is mission reports. Mission reports are available in many forms and are provided primarily to MAGTF intelligence elements in response to established intelligence requirements. The most commonly used reporting form is the TACELINT (refer to USSID 340, *Tactical ELINT Reporting*, for format and content).

Other report forms include the following:

- TACREP provides information on immediate threat activity.
- ELINT summary report provides a summary of ELINT activity over established periods (normally 24 hours). Refer to USSID 200 *Technical SIGINT Reporting,* for format and content.
- ELINT technical report provides for analyst exchange of information of parametric data. Refer to USSID 341, *Technical ELINT Reporting*, for format and content.
- Over the horizon (OTH) "GOLD" report provides information derived from contac reports of ELINT parametrics.
- Order of battle report (OBREP) provides order of battle information such as basic encyclopedia (BE) number, equipment, and location.

Chapter 6

Communications and Information Systems

The area of SIGINT operations currently undergoing substantial change is SIGINT CIS technological advances and architectures development. SIGINT architectures are changing from the use of separate, secure, 24-hour manned communications centers with dedicated, bulk-encrypted links to the use of multilevel information system security initiative (MISSI) capabilities over unsecured commercial or DOD networks via the Defens Message System (DMS). Adding the proliferation of SIGINT collection, processing, and production systems and centers along with other intelligence and operations systems and centers that must disseminate and share SIGINT and communicate digitally creates a very dynamic situation.

The SIGINT effort depends heavily on a secure, reliable, and fast CIS architecture to receive SIGINT and all-source intelligence products and to pass collected data and SIGINT products and technical reports to the MAGTF and other users. Communications and information systems are also required for the C2 of SIGINT units and their integration with multidiscipline intelligence operations. Every mission and situation is unique, requiring some modifications to the CIS architecture supporting MAGTF SIGINT operations. Detailed planning and close coordination among the SIGINT units' CO or OICs, the MAGTF G-2/S-2 and G-6/S-6, and pertinent operational and intelligence organizations is critical to establishing reliable and effective SIGINT architecture.

See appendix B, Marine Corps SIGINT Equipment, of this publication for additional information on select communications and information systems resources pertinent to MAGTF SIGIN operations. Also, see MCWP 6-22, *Communications and Information Systems*, for a detailed review of MAGTF CIS and supporting tactics, techniques, and procedures.

6001. Basic MAGTF SIGINT CIS Requirements

a. Capability to Command and Control Subordinate Units

MAGTF SIGINT units must be capable of positive C2 of subordinate units and integration of its operations with broader MAGTF and external intelligence and operations C2. Traditionally, single-channel radio (SCR) and record message traffic have been used to support C2 of SIGIN units. In semistatic situations, secure electronic mail or the telephone may be the method of choice, while in highly fluid or mobile scenarios, cellular telephones, satellite communications (SATCOM), VHF, or HF radio may be used.

b. Ability to Receive and Transmit Collected Data and Information from Collection and DF Elements

The SIGINT architecture must provide connectivity among organic and supporting SIGINT collection or DF teams, SIGINT analysis and production centers, and supported MAGTF operations and intelligence centers. Requirements include the capability to receive and transmit collection files and reports digitally via fiber, wire, or radio (voice and data) in formats that are

readily usable by the SIGINT and all-source intelligence analysts.

c. Ability to Provide Intelligence to the Supported Commander

The required SIGINT architecture must support the commander's intent, concepts of operation and intelligence, command relationships, and standing PIRs and IRs. The SIGINT CIS architecture must be capable of integrating SSU SCI-secure channels and C2 operations with the primary GENSER channels used by supported commanders throughout the MAGTF.

d. Ability to Share SIGINT Products and Technical Reports

The SIGINT architecture must provide the means to share products and reports with MAGTF all-source intelligence centers and with SIGINT and all-source JTF, other components, theater, and national intelligence centers. The traditional means for providing this capability are the SCI secure defense special security communication system (DSSCS) for record communications and operator's communications (OPSCOM) circuit for SIGINT analyst-to-analyst exchanges and coordination. These means are rapidly being replaced by—

- JWICS which provides interoperability of intelligence systems, access to intelligence data bases, and direct analyst-to-analyst exchange.
- National Security Agency Network (NSANET) which provides access to national-level SIGINT reports and data bases and electronic mail connectivity for SIGINT analyst-to-analyst exchanges and intelligence requests.

e. Ability to Receive and Disseminate SIGINT Indications and Warnings

A significant strength of SIGINT is its ability t provide time-sensitive I&W of the adversary's actions and intentions. This I&W intelligence is disseminated by a variety of means to include voice, record messages, tactical reports, electronic mail, and intelligence broadcasts. Having the capability to receive the information, recognizing the I&W intelligence as such, and possessing a method to disseminate this I&W intelligence to the affected units and decisionmakers are key to satisfying this requirement.

f. Ability to Receive SIGINT Broadcasts

For several years MAGTFs have possessed intelligence broadcast receivers capable of accessing select SIGINT broadcasts. The broadcast receivers currently being fielded and under development will allow MAGTFs to receive multiple channels of JTF, fleet, theater, and national intelligence broadcast data. This data includes all-source intelligence and SIGINT on enemy operations as well as friendly positional and other information. Effective planning, design, and integration of SCI and GENSER CIS and proper information management filtering, correlating, and tailoring prior to dissemination or display provide timely SIGINT reporting to supported commanders while preventing information overload.

6002. Notional MAGTF SIGINT Operational Architectures

a. MEF

Figure 6-1 depicts a notional SIGINT operational architecture for a fully deployed MEF. It shows a full complement of organic and supporting JTF other service components, theater, and nationa SIGINT capabilities.

Key architectural concepts include the following:

- SIGINT operations planning and management are centralized within the MAGTF G-2/S-2.

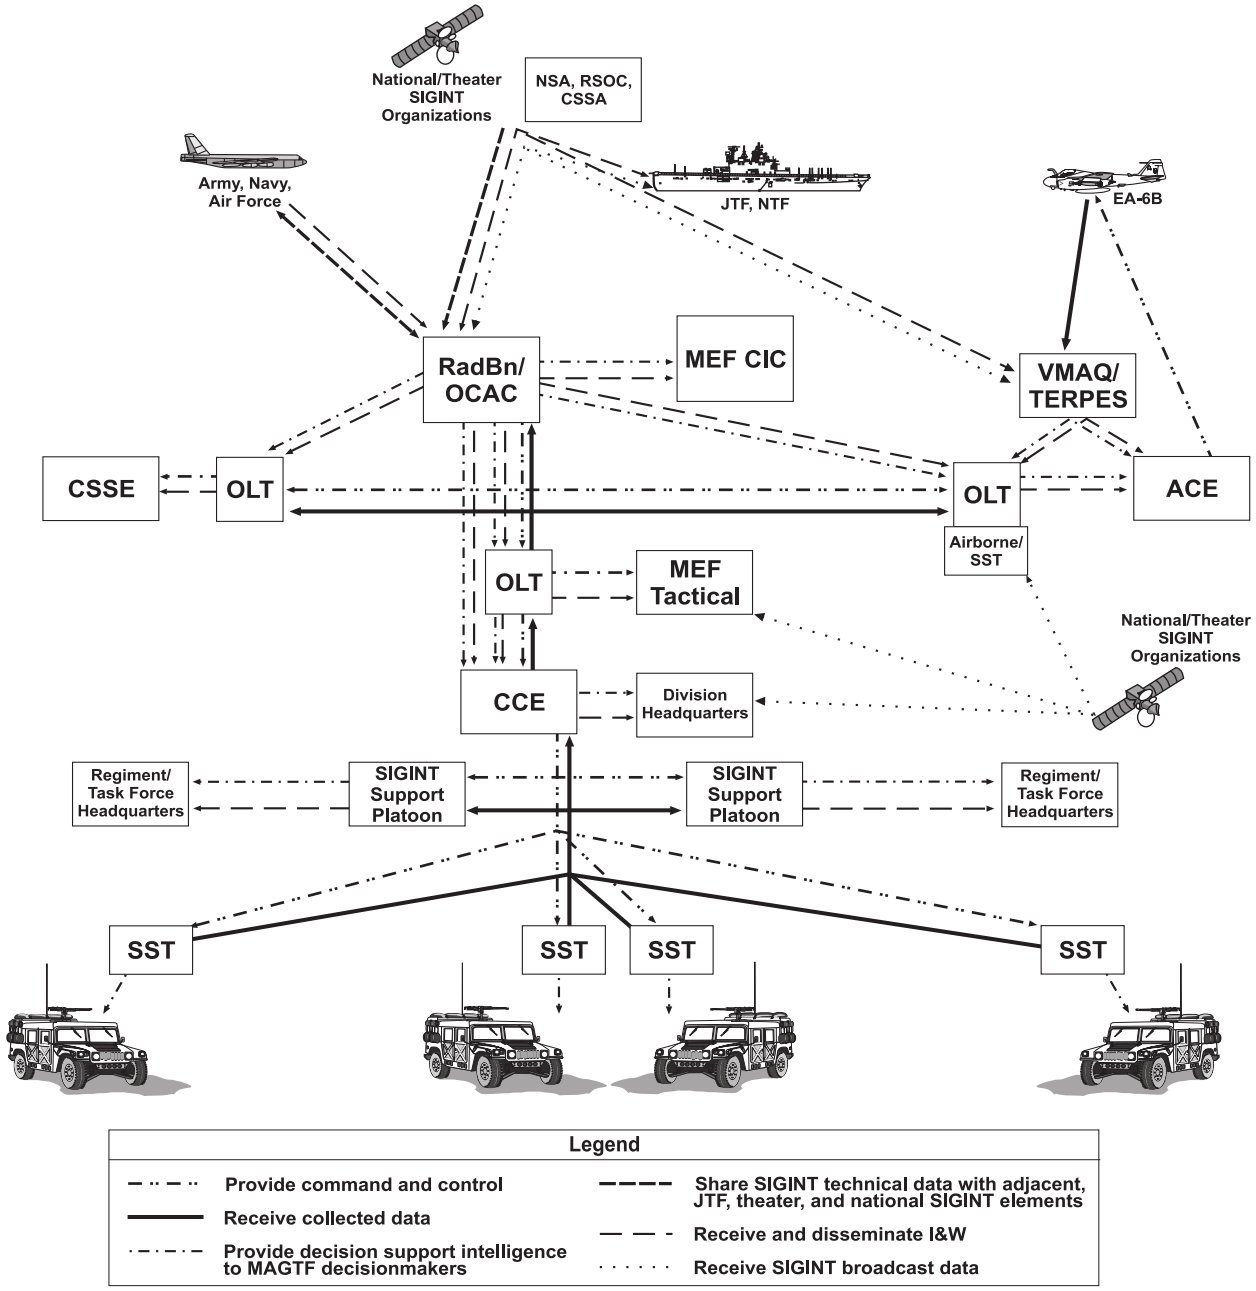

Figure 6-1. Notional MEF SIGINT Operational Architecture.

- **RadBn OCAC is collocated with the G-2/ S-2 CIC and operates in general support of the MAGTF, with collection or DF teams collocated with forward-deployed MAGTF units.**
- **VMAQ TERPES is collocated with ACE headquarters and principally supports ACE operations.**
- **MAGTF CIC, RadBn OCAC, and TERPES maintain connectivity with appropriate**

external intelligence and SIGINT organizations.

b. MEF Lead Echelon

Figure 6-2 shows a notional operational architecture in support of the MEF lead echelon during its initial deployment and employment phases. SIGINT operations focus on the MEF as it deploys into the area of operations and builds its combat power.

Key architectural concepts include the following:

- SIGINT operations planning and management remain centralized within the MAGTF G-2/S-2, which is not yet within the area of operations.
- RadBn fly-in echelon is collocated with lead elements of the MAGTF G-2, with organi teams operating in GS of deployed elements. RadBn OCAC is collocated with the G-2/S-2 CIC.
- VMAQ TERPES is collocated with ACE headquarters and principally supports ACE operations.

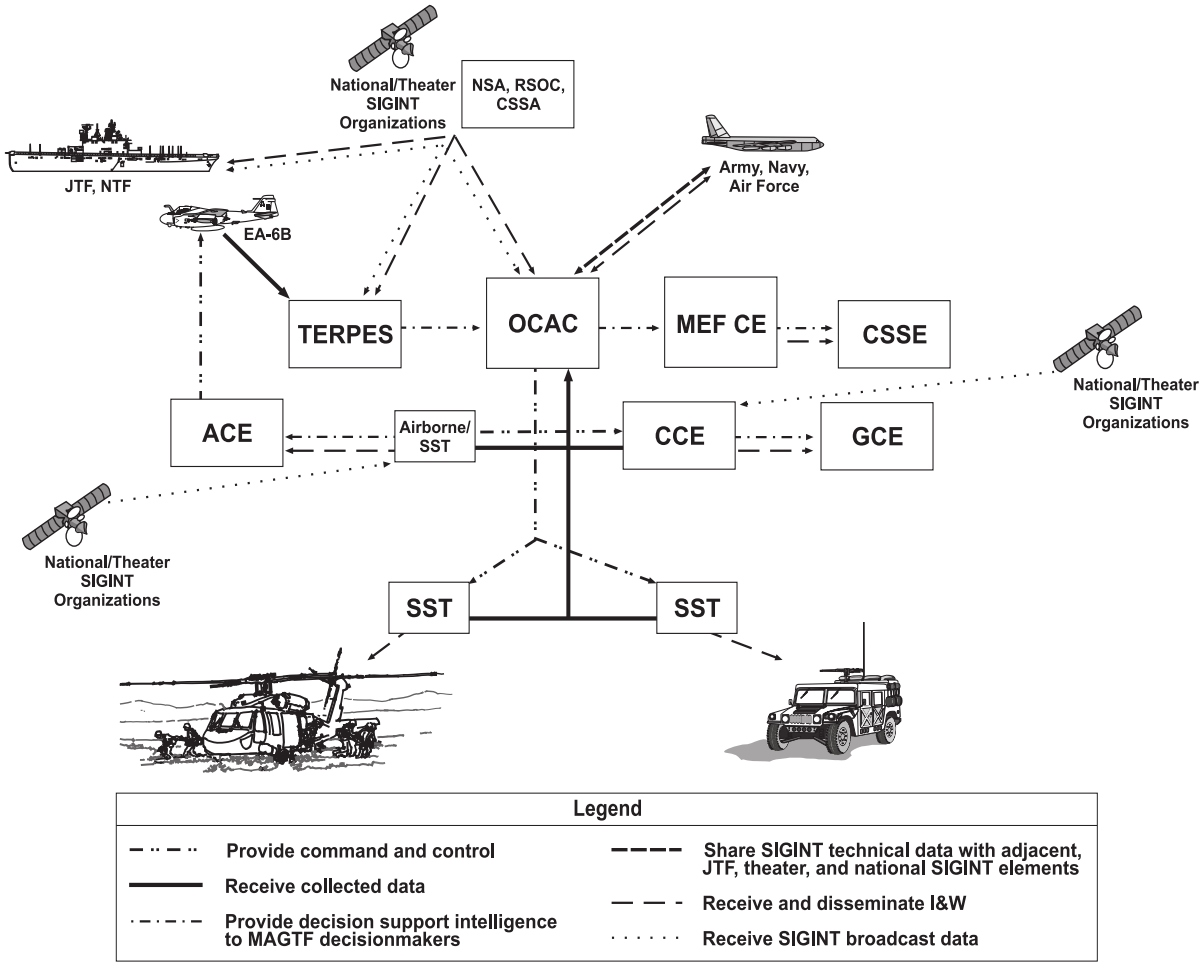

Figure 6-2. Notional MEF Lead Echelon SIGINT Operational Architecture.

- **MAGTF CIC, RadBn OCAC, and TERPES maintain connectivity with appropriate external intelligence and SIGINT organizations.**

c. MEU(SOC) CE Afloat

Figure 6-3 shows a notional operational architecture in support of a MEU(SOC) afloat. During such operations, MEU and ATF SIGINT capabilities and organizations generally collocate within the same afloat facilities (e.g., SSESs) integrate and share some systems operations. A critical component of this architecture is satisfactor voice and data ship-to-shore SCI communications between the MEU(SOC) command element and ashore SIGINT elements.

Key architectural concepts include the following:

- **SIGINT operations planning and management are centralized in the MEU(SOC) S-2.**
- **RadBn SSU OCAC operates out of the SSES collocated with the S-2 CIC within the amphibious task force intelligence center (ATFIC). RadBn operates in general support of the MAGTF. Depending on the mission, RadBn collection and DF elements may operate in either general support of the MAGTF or direct support of elements operating ashore.**
- **MAGTF CIC and RadBn OCAC maintain connectivity with appropriate external intelligence and SIGINT organizations.**

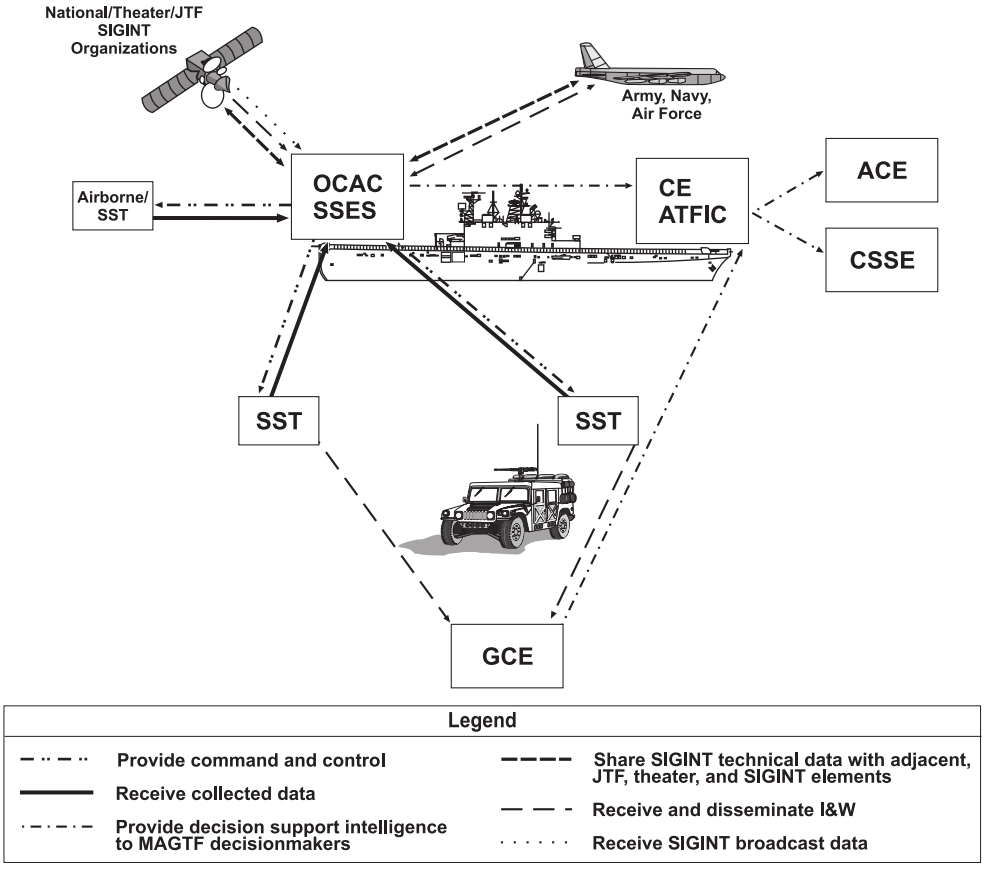

Figure 6-3. MEU(SOC) CE Afloat SIGINT Operational Architecture.

d. MEU(SOC) CE Ashore

Figure 6-4 depicts a notional operational architecture in support of a shore-based MEU(SOC) CE. The MEU(SOC) requires ship-to-shore SCI communications connectivity to continue exploiting external SIGINT capabilities and resources while minimizing the CIS and logistic footprints ashore.

Key architectural concepts include the following:

- **SIGINT operations planning and C2 remain centralized within the MEU(SOC) S-2.**
- **The MAGTF RadBn SSU OCAC is collocated ashore with the S-2 CIC. Other SSU elements provide continued support from the amphibious task force intelligence center SSES.**
- **RadBn SSU normally will operate in GS of the MAGTF.**
- **MAGTF CIC and RadBn OCAC principal connectivity with appropriate external intelligence and SIGINT organizations is via the amphibious task force intelligence center SSES.**

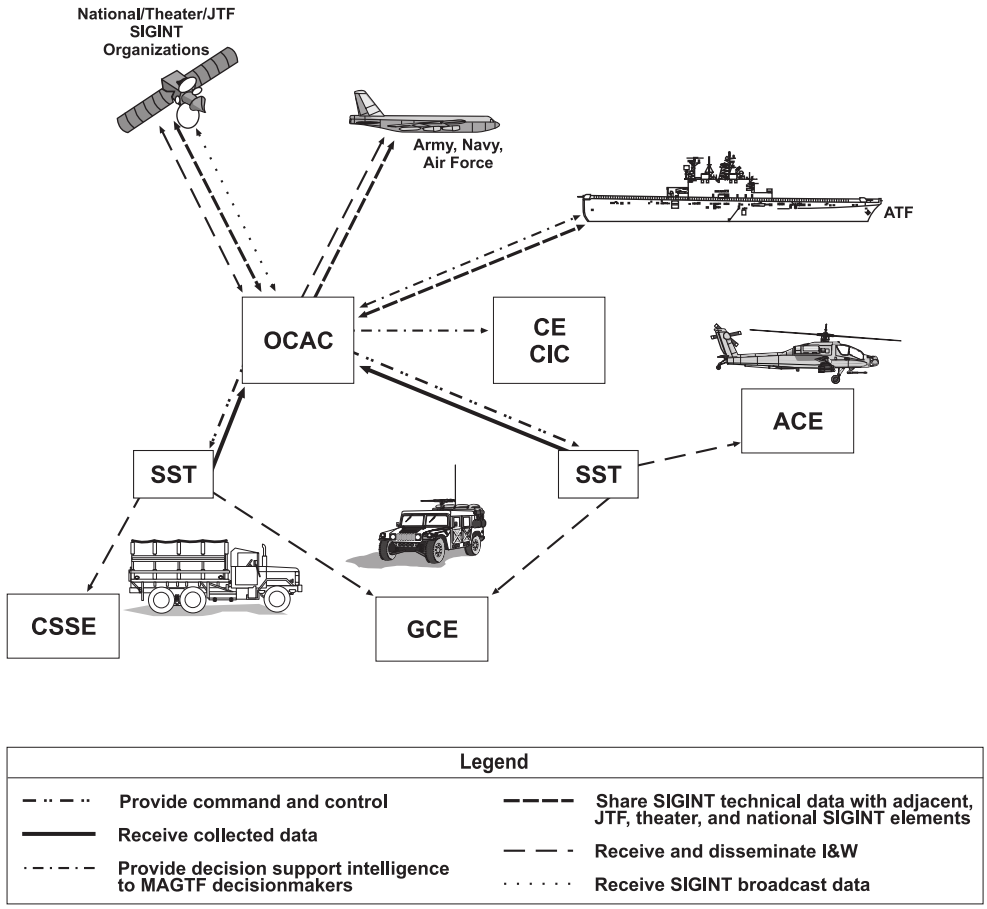

Figure 6-4. MEU(SOC) CE Ashore SIGINT Operational Architecture.

6003. Planning Consideration

The following are key CIS requirements and planning considerations in support of MAGTF SIGINT operations.

- Add the MAGTF CE, RadBn SSU, VMAQ TERPES, and other MAGTF elements to appropriate addressee indicator groups (AIGs) to receive pertinent JTF, theater, and national intelligence and SIGINT products.
- Obtain and activate SCI plain language addresses for MAGTF CE, RadBn SSU, and other MAGTF elements as appropriate.
- Determine and coordinate radio nets, supporting frequencies, and procedures for—
  - MAGTF external SIGINT operations.
  - MAGTF internal SIGINT operations.
  - Intelligence broadcasts.
  - Retransmission sites.
  - Routine and time-sensitive operations.
- Obtain authority and establish procedures for the sanitization of SIGINT products, reports, and other information.
- Determine and coordinate wire communications, to include telephones.
- Determine and coordinate SCI and GENSER LANs and WANs and unique intelligence networks information systems requirements (e.g., hardware, software, internet protocol addresses).
- Determine and coordinate SCI-courier requirements and operations.
- Integrate RadBn SSU and VMAQ CIS operations with those of other MAGTF and pertinent JTF and other components intelligence and reconnaissance units (e.g., mutual support, cueing).
- Integrate RadBn SSU, SSE, and SST, and VMAQ TERPES communications with collocated GCE, ACE, CSSE, and other MAGTF elements to—
  - Provide time-sensitive I&W and noncodeword (NCW) SIGINT reporting.
  - Coordinate with maneuver forces.
  - Support targeting.
  - Support force protection.
- Coordinate SIGINT CIS and dissemination operations and procedures with allied and coalition forces.
- Coordinate SCI and SIGINT CIS activation and restoration priorities and procedures.
- Determine unique COMSEC material system (CMS) requirements for SIGINT and SCI communications.
- Determine communications requirements between TSCIFs and mobile SCIFs and supporting security forces.

6004. SIGINT Communications

The SIGINT CIS architecture for any given operation is dynamic. Specific theater, JTF, or MAGTF reference documents include—

- CSPs developed for various OPLANs.
- Combatant commanders intelligence, CIS, and SIGINT tactics, techniques, and procedures (TTPs).
- Annexes B (intelligence), C (operations), and K (communications) of an OPORD.
- Appendix 2 (SIGINT) to annex B of an OPORD.

The MAGTF mission, threat signals environment, friendly concepts of operations and intelligence, and supporting task organization and command relationships influence which communications nets are established.

The following information addresses importan aspects of systems and technical architectures in support of MAGTF SIGINT operations.

a. MAGTF Command Element SIGINT Communications Nets

Figure 6-5 shows aspects of a notional CIS architecture for the MEF CIC. The following key SIGINT communications nets terminate within the MAGTF CE CIC or RadBn SSU.

(1) MAGTF DSSCS or Special Intelligence Communications Net External (HF). The DSSCS provides the MAGTF commander with a secure data communications channel for the exchange of SCI information and the receipt of record communications. The path is provided by the supported commander, and the terminal equipment and personnel are provided by the RadBn SSU. Key net participants include—

- The MAGTF CE via the RadBn SSU's special security communications element.
- Commander, joint task force (CJTF).
- Commander, amphibious task force (CATF).
- Other theater and national organizations.

(2) MAGTF Critical Communications Net (UHF-SATCOM/VHF). The critical communications (CRITICOMM) net provides the MAGTF commander communications with adjacent service cryptologic and other SIGINT and JTF elements and theater cryptologic support groups The path is provided by the supported commander, and the terminal equipment and personnel are provided by the RadBn SSCT. Key net participants include—

- MAGTF CE via the RadBn or SSU special security communications element.
- JTF.
- Adjacent headquarters.
- Theater and national intelligence or SIGINT agencies.

(3) Theater Cryptologic Support Net (HF/UHF-SATCOM). Theater cryptologic support net provides for rapid exchange of cryptologic information with the SIGINT elements of other organizations. The path is provided by the supported commander, and the terminal equipment is provided by the RadBn/SSU. Key participants include—

- RadBn OCAC.
- Adjacent service cryptologic elements.
- JTF or ATF SIGINT agencies.
- Theater and national SIGINT agencies.

(4) Tactical Receive Equipment and Related Applications Program Data Dissemination System. The TRE and related applications program data dissemination system (TDDS) broadcast provides I&W and global surveillance information in time for sensor cueing. Data is forwarded from sensor to communications gateways or relays for dissemination to worldwide military users via geosynchronous UHF satellite links. TDDS data sources include national and tactical sensor systems. Participants include the MAGTF CE CIC or SSU OCAC and other JTF, theater, and national intelligence centers and agencies.

(5) Tactical Information Broadcast Service. The tactical information broadcast service (TIBS) provides near-real-time intelligence from an open network of interactive participants using multiple sensors and sources. The TIBS broadcast uses UHF SATCOM assets for network operation and for the relay of out-of-theater specific information into the tactical users' areas of operation. TIBS participants include a wide variety of national and Service airborne, surface, and subsurface intelligence platforms. The broadcast will terminate in the MAGTF CE CIC or SSU OCAC.

(6) Tactical Intelligence Net. Tactical intelligence (TACINTEL) net is an automated, high speed data link for transmission and reception of SCI (data and voice) among SIGINT collection and production units during amphibious operations. Key participants include naval expeditionary force (NEF) and ATF SIGINT centers (within the SSES) and the RadBn and SSU OCAC.

(7) MAGTF-Internal Special Intelligence Communications Net (VHF/UHF/SHF). Special intelligence communications (SPINTCOMM) net provides the MAGTF commander with secure SCI communications with subordinate division or wing commanders through their organic SSCT.

The path is provided by the supported commander, and the terminal equipment and personnel are provided by the RadBn SSU or SSCT.

(8) TROJAN SPIRIT II Net. The Trojan Spirit II net (C and Ku band SATCOM) receives and disseminates intelligence information over a special-purpose satellite system. Key participants include the MAGTF CE CIC, RadBn SSU OCAC, amphibious task force intelligence center SSES and various external intelligence agencies and organizations.

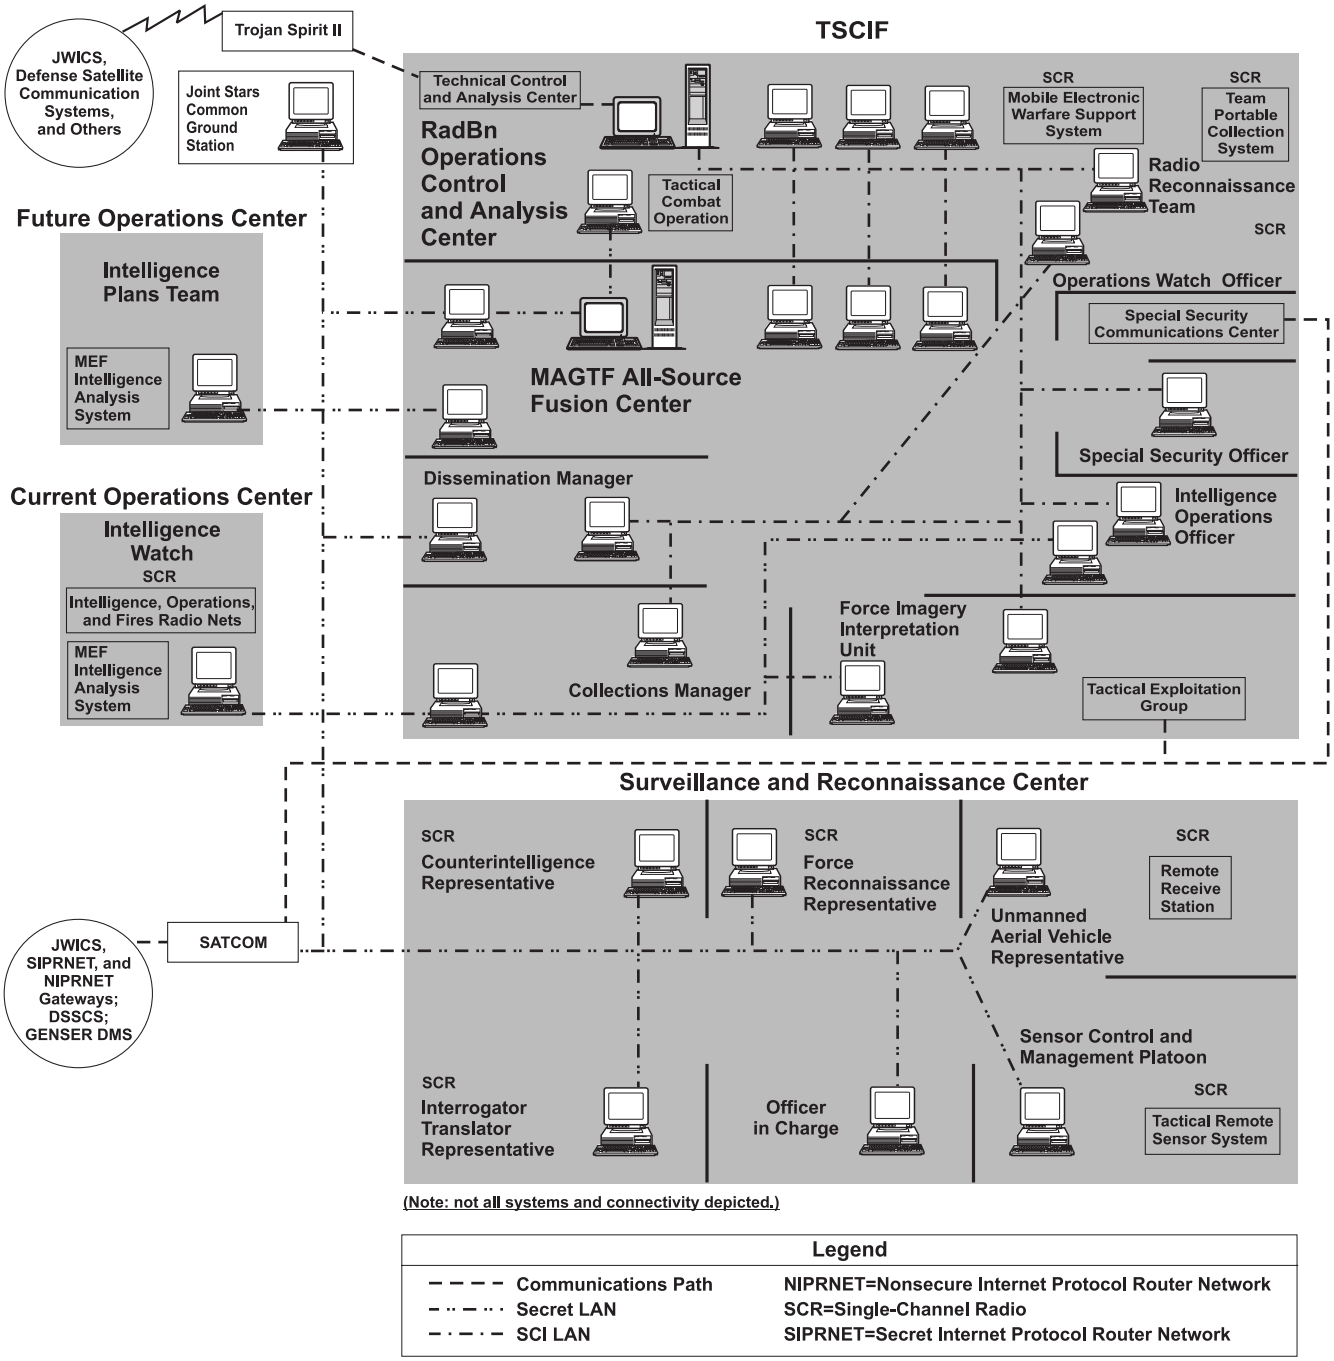

Figure 6-5. MEF CE CIC Communications and Information Systems Architecture.

b. Radio Battalion SIGINT Support Unit Internal Communications Nets

Figure 6-6 shows key aspects of the CIS architecture for the internal operations of the RadBn SSU. The following key communications nets terminate within the RadBn SSU OCAC.

(1) Command and Control Net (HF/VHF). The RadBn SSU C2 net provides the battalion commander or detachment OIC with C2 of subordinate elements. The path, equipment, and personnel are provided by the RadBn. Key net participants include the RadBn SSU OCAC and deployed collection and DF, EA, and RRT teams.

(2) Collection and Reporting Net (UHF-SATCOM/HF/VHF). The collection and reporting net provides C2 and SIGINT reporting net for RadBn SSU collection operations. Key participants include the OCAC and deployed collection and DF teams.

(3) Electronic Attack Control Net (VHF). The EA control net provides direction and control of RadBn EA teams and assets. The path, equipment, and personnel are provided by the RadBn SSU. Key participants include the OCAC and deployed MEWSS and EA teams.

(4) Direction Finding Flash Net (VHF). The DF flash net provides the DF control station with a means of broadcasting DF flashes to DF teams. The path, equipment, and personnel are provided by the RadBn. Key participants include the OCAC's DF control and deployed collection and DF teams.

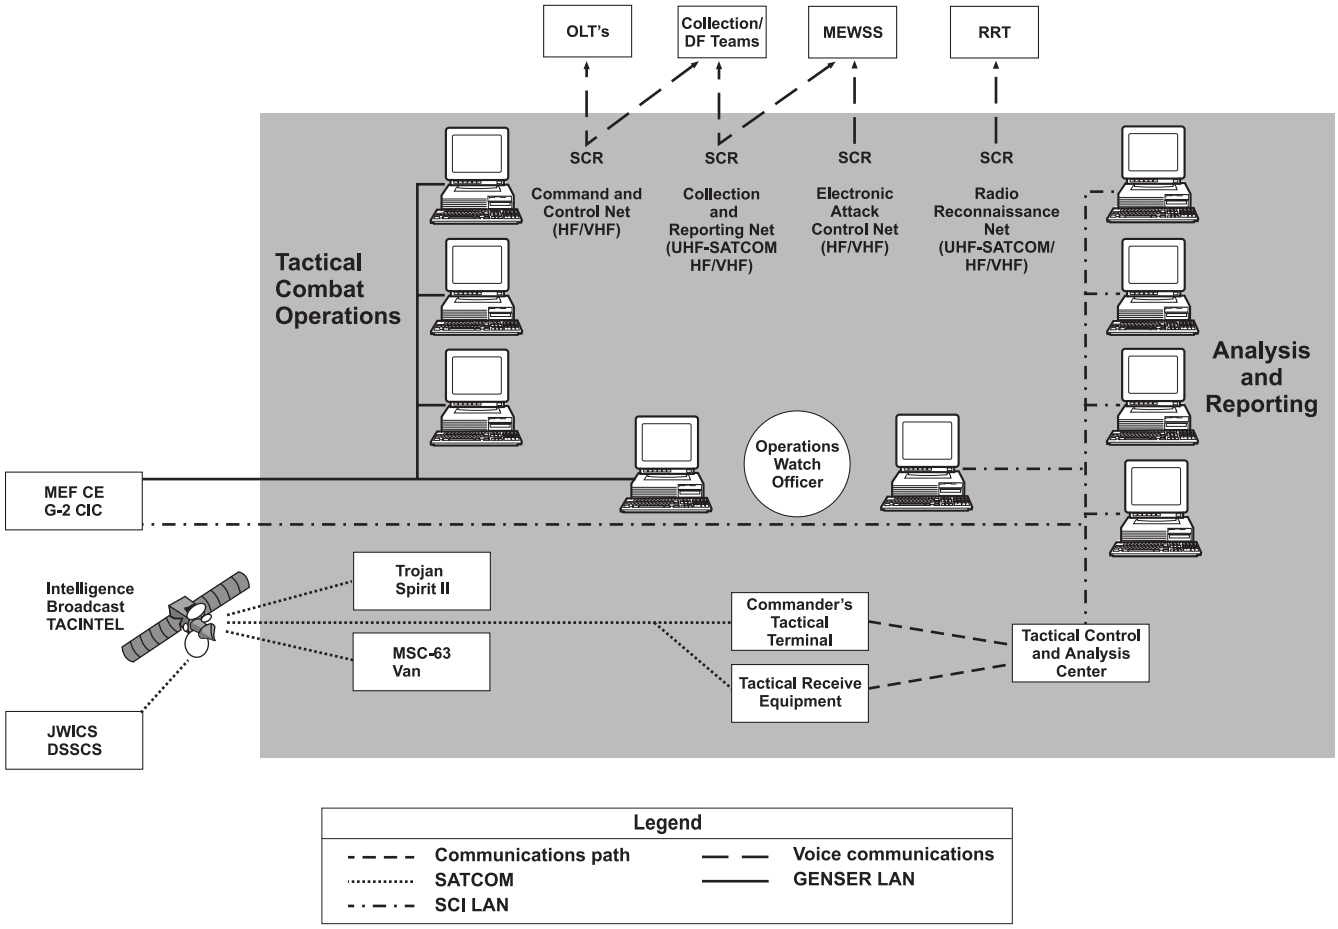

Figure 6-6. RadBn SSU Operations Control and Analysis Center Communications and Information Systems.

(5) Direction Finding Report Net (VHF). The DF report net provides reporting from DF outstations to the OCAC DF control. Path, equipment, and personnel are provided by the RadBn SSU.

(6) Direction Finding Data Net (VHF). The DF data net exchanges DF information between the deployed collection and DF team and the OCAC DF control. The path, equipment, and personnel are provided by the RadBn.

(7) Mission Equipment Control Data Link Net (UHF). The mission equipment control dat link (MECDL) net provides the means to control, coordinate, and monitor the mission equipment of MEWSS teams. This net is used for internal MEWSS operations and for interface and coordination with the Army intelligence and EW common sensor systems.

(8) Tasking and Reporting Net (VHF) The tasking and reporting net provides a means for the RadBn to task deployed collection teams and to report SIGINT information.

(9) Radio Reconnaissance Command Net (UHF-Tactical Satellite/HF) The radio reconnaissance command net provides the means to command and control deployed RRTs and their reporting of SIGINT collection and DF reports to the RadBn SSU OCAC.

c. Marine Tactical Electronic Warfare Squadron Communications Nets

Figure 6-7 shows key aspects of the CIS architecture for VMAQ TERPES operations. The following key SIGINT communications nets terminate within VMAQ operations or TERPES elements.

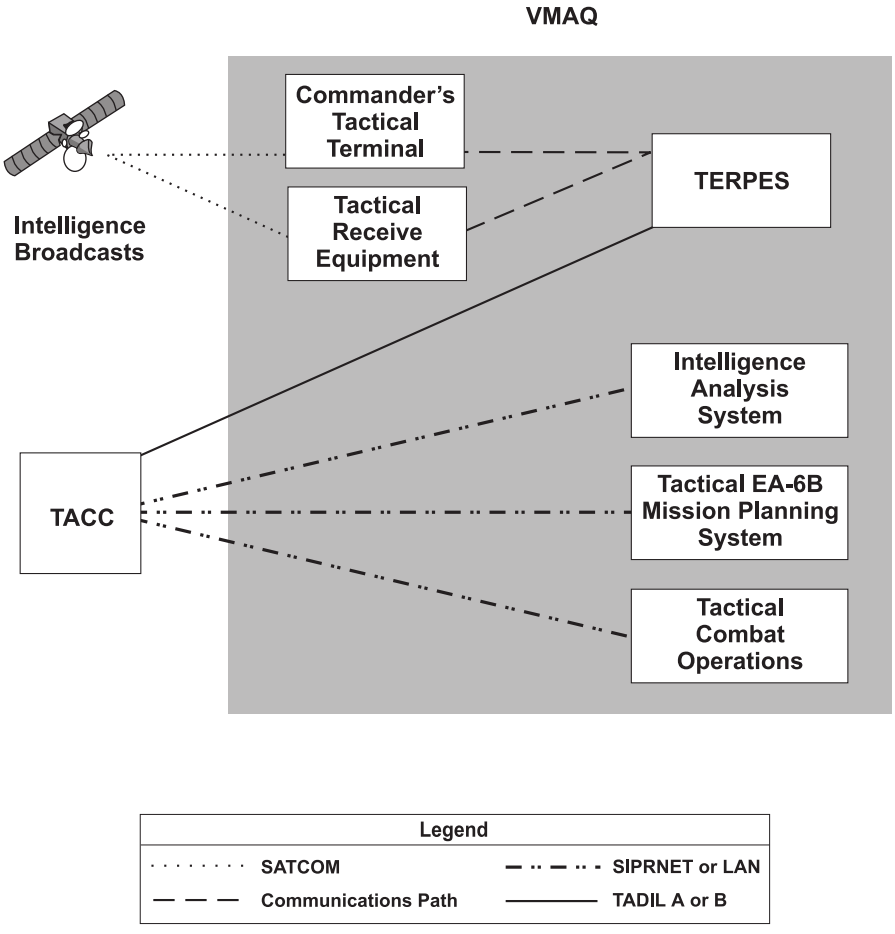

Figure 6-7. VMAQ Operations Center and TERPES Communications and Information Systems.

(1) Aviation Combat Element Command Net (HF). The ACE command net provides a means for the ACE commander to exercise command and coordinate subordinate units' administrative and logistic functions. Composition includes ACE headquarters, MAG detachments Marine air control group or detachment, and independent squadrons or battalions.

(2) Aviation Combat Element Intelligence Net (VHF/HF/UHF). The ACE intelligence ne provides a means for rapid collection and dissemination of intelligence between the ACE headquarters and subordinate units. Composition includes the ACE headquarters, the TACC, MAGs or squadrons headquarters, the tactical air operations center (TAOC), direct air support center (DASC), TERPES, and others as appropriate.

(3) Tactical Digital Information Link A (HF/UHF). Tactical digital information link A (TADIL-A), also called Link-11, is used to exchange tactical data in real time among ships, aircraft, and shore sites. TADIL-A messages provide navigational data, surface and subsurface tracks, and operational orders. TADIL-A is an encrypted half-duplex system. It can be used on either H single- or dual-sideband or UHF frequencies.

There are two data rates:

- Fast, at 2250 bits per second (bps) which is the most used data rate.
- Slow, at 1364 bps.

TADIL-A is available within the United State Navy, Air Force, Marine Corps, and Army. The MAGTF's C2 nodes that can use TADIL-A are the TAOC and the TACC. The exchange of digital information by TADIL-A is accomplished by net-configured participating units (PUs) under the control of a net control station (NCS). A net can be composed of as few as two PUs (e.g., TERPES, via the TACC, and the TAOC).

(4) Tactical Digital Information Link B (Multichannel Radio). TADIL-B, multichannel radio (MUX), (also known as Link-11B) is a full-duplex, point-to-point, encrypted system that simultaneously exchanges tactical data between two units capable of TADIL-B at a rate of 600 1200, and 2400 bps. TADIL-B messages provide navigational data, surface and subsurface tracks, and operational orders. It may use VHF, UHF, SHF, and ground mobile force-SATCOM MUX systems. Additionally, TADIL-B can also be exchanged over wire. TADIL-B is used by the United States Air Force, Army, and Marine Corps. MAGTF C2 nodes with TADIL-B capability are the TACC, TAOC, and Marine air traffic control detachment (MATCD). Participants on a TADIL-B network, such as TERPES, are called reporting units (RUs). Some RUs are capable of simultaneously linking with several other RUs. Those units that can redistribute the information re ceived from one RU to another RU are called forwarding reporting units (e.g., TACC and TAOC).

(5) Tactical Digital Information Link C (UHF). TADIL-C, also called Link-4A, is used by the North Atlantic Treaty Organization (NATO) and the United States Armed Forces. TADIL-C is an unencrypted, computer-to-computer digital information link that operates in the UHF frequency range at 5000 bps. The TADIL-C link is between a controlling unit and a controlled tactical aircraft. TADIL-C is a valuable means for providing radar track correlated symbology both up to the aircraft and, in the case of two-way transmissions, back down to the controlling agency. The MAGTF TAOC uses the TADIL-C for one-way and two-way links to control F-14, F/A-18, EA-6B, and S-3 aircraft.

(6) Voice Product Net (UHF). The voice product net (VPN) provides a communications means for forwarding nondigital intelligence information to other intelligence and operations elements. Key MAGTF participants include the TACC, TAOC, EA-6B, and TERPES, as well as other MAGT external platforms (e.g., Rivet Joint, Compass Call, EP-3).

Chapter 7

Planning and Operations

The purpose of SIGINT operations is to develop intelligence on the enemy's capabilities, intent, and operations by exploiting the enemy's use of communication, radars, and electronic systems.

Section I. SIGINT Functional Planning

Detailed planning must precede actual SIGINT operations to take advantage of the wealth of information available on the adversary's signals emanations and operations.

7101. SIGINT Concept of Operations

SIGINT operations must support the commander's intent, concept of operations, and the supporting concept of intelligence operations.

Questions that must be answered to develop the SIGINT concept of operations include the following:

- What is the MAGTF area of operations (AO) and area of interest (AI)?
- What is the MAGTF concept of operations, task organization, and main and supporting efforts? Does the friendly concept of operations allow for fixed-site SIGINT collection and DF operations, mobile collection and DF operations, or both?
- What are the standing PIRs and IRs? Which have been tasked to SIGINT units? What specific information is the commander most interested in (e.g., enemy air operations, enemy ground operations, friendly force protection, target battle damage assessment [BDA], or enemy future intentions)?
- What is the MAGTF force protection concept of operations?
- What is the MAGTF concept of fire support? How will MAGTF target development and target intelligence be conducted?
- What are the SIGINT and intelligence concepts of operations of other JTF components, the JTF, and theater resources? What are the task organization and command or support relationships for all other MAGTF intelligence and reconnaissance units?
- How can shipboard SIGINT assets and other JTF, theater, and national SIGINT assets be integrated and employed to support MAGTF operations?

7102. Enemy Characteristics

Intelligence operations focus on the enemy. Prior to commencing SIGINT operations, MAGTF intelligence personnel must learn as much as they can about the following enemy C2 CIS practices.

a. Size and Composition of Enemy Forces

- What threat forces are within the MAGTF AO and AI?
- What are the enemy's centers of gravity and critical vulnerabilities?
- Is this a large enemy force organized along conventional military lines or a small, loosely knit guerrilla or unconventional military force?

b. Enemy Command and Control and Supporting Communications and Information Systems

- What and where are the enemy's critical C2 nodes and what are their vulnerabilities?
- What types and categories of communications nets and networks are used by the enemy?
- What echelons of command do the communications nets and networks serve?
- What are the associated communications and noncommunications electronic emitters?
- What are the tactics, techniques, and procedures used for enemy CIS operations? How do they relate to various threat functional activities?
- How is information transferred among the enemy's units and command echelons?
- Does the enemy employ communications emitters at all levels of command or does it rely on communications means less exploitable by SIGINT (e.g., fiber, wire, and messenger)?

c. Emitter Technical Data

Effective SIGINT operations require extensive technical information on the enemy's CIS resources and operations. See table 7-1 for key threat emitter technical data requirements.

Table 7-1. Emitter Technical Data.

Aspect	Technical and Operational Characteristics
Communications Operations and Emitters	
Frequency range and use	HF, VHF, UHF, etc.
Call sign use	Rota, random, etc.
Transmitter power	Hearability, SIGINT collection, and DF location requirements
Emission type	Single, multichannel, spread spectrum, frequency hopping, burst, etc.
Signal type	Analog or digital
Modulation	AM, FM, PCM, etc.
Cryptologic system	Public, private key, none
System type	Voice, data, teletype, facsimile, video, combinations of some or all
Language use	Dialect, written, or voice
Miscellaneous	Communication procedures, emissions control practices, use of deception, security systems, etc.
Noncommunications Operations and Emitters	
Location	Fixed, mobile
Platform	Air, ship, vehicle, fixed-installation
Associated C2 node or weapon system	Command post, type of weapon system
Frequency range	Band of operation
Modulation characteristics	Pulse duration, pulse repetition frequency, etc.
Transmitter power	Effective radiated power, effective range
Purpose of function	Jamming, surveillance, targeting, C2, fire control, etc.

7103. Topography

Terrain, physical obstructions, and vegetation in the area of operations have a major effect on the employment of SIGINT resources and their ability to exploit enemy signals. Proper placement of SIGINT collection and DF assets is essential for effective reception of adversary emanations. Several factors affect reception quality.

a. Target Frequencies

Many of the frequency ranges and power levels in use by the world's military and paramilitary forces require line-of-sight (LOS) or near-LOS paths from transmitter to receiver. Generally, the higher the frequency used, the greater the LOS influence and the more critical the accurate placement of SIGINT collection and DF equipment. Lower

frequencies (particularly those below 30 MHz) generally do not require LOS paths. Consequently, the placement of SIGINT collection and DF sites to exploit these frequencies may be located at greater distances from the target transmitters.

b. Power Output

The power output of a transmitter is an important factor in receiving the signal. To intercept some low-powered signals, SIGINT collection and DF assets must be located closer to the adversary's transmitter, often requiring SIGINT collection and DF teams to either collocate with or closely follow forward MAGTF combat units.

c. Antennas

If the targeted adversary's system uses highly directional antennas, as do many multichannel systems, the SIGINT collection and DF site must be placed within the adversary's antenna radiating pattern.

7104. Planning Responsibilities

Primary staff responsibility for SIGINT operations planning lies with the G-2/S-2. The G-2/S-2 responsibilities are—

- Preparing integrated, multidiscipline intelligence and reconnaissance operations, to include supporting SIGINT plans, orders, annexes, and appendices.
- Coordinating with the G-3/S-3 to ensure—
  - Planned SIGINT effort will support the concept of operations and scheme of maneuver.
  - SIGINT and EW operations are effectively prioritized and integrated.
  - Adequate site placement and security for SIGINT collection elements is provided.
- Coordinating with the G-6/S-6 officer for CIS support to the SIGINT elements, including circuits and networks access, frequency assignment, equipment, and call signs.
- Acting as liaison with SIGINT agencies and units external to the MAGTF.
- Coordinating with the G-4/S-4 to ensure adequate logistics support of SIGINT elements (e.g., transportation and maintenance of SIGINT units' unique equipment).

7105. Coordination of SIGINT Operations

a. Internal Coordination

Internal MAGTF SIGINT requirements must be coordinated with maneuver, fires, electronic warfare, force protection, and CIS requirements. This coordination may occur within the EWCC under G-3/S-3 staff cognizance, within the CIC, or within the OCAC, depending upon the task organization and C2 and support relationships in effect. Additionally, collection and DF team movements and locations must be coordinated with the MAGTF's tactical movements to ensure continuous support without interference.

These efforts are accomplished through planning and close coordination among the following MAGTF staff officers:

- MAGTF G-2/S-2, the intelligence operations officer, and the intelligence battalion commander.
- SIO, MAGTF AFC OIC, collections officer, SARC OIC, and the dissemination manager.
- MAGTF G-3/S-3 future and current operations officers, C2W officer, and EWO.
- MAGTF G-6/S-6.
- GCE, ACE, and CSSE staff officers.
- RadBn SSU and VMAQ TERPES COs and OICs.

b. External Coordination

(1) Higher Headquarters and External Organizations. The MAGTF G-2/S-2 and all SIGINT planners must coordinate SIGINT operations, activities, and requirements with DIRNSA. Accordingly, a continuous exchange of

data and information is required. This requires JWICS access and special security communications circuits for the exchange of SIGINT technical data and intelligence information.

(2) Adjacent and Area SIGINT Activities. MAGTF SIGINT activities must be coordinated with other SIGINT activities within the joint operations area and theater to reduce duplication and to ensure maximum use of available assets and mutual support. For example, an NSG-fixed site outside the MAGTF tactical operations area could be conducting SIGINT collection and DF against targets within the MAGTF area of responsibility. With proper planning and coordination, external SIGINT assets of the combatant commander, JTF, and other components can provide SIGINT support to the MAGTF (e.g., product reporting, exchanges of technical information), allowing organic MAGTF SIGINT resources to focus on critical targets.

Section II. SIGINT Operational Planning

This section provides a general description of the SIGINT planning cycle and activities to enable an understanding and appreciation for the SIGINT effort as a whole. No attempt is made to provide technical details for SIGINT processing. The SIGINT cycle is in concert with the following six phases of the intelligence cycle (see MCWP 2-1 for additional information on the intelligence cycle and intelligence planning).

7201. Planning and Direction

The planning and direction phase of the intelligence cycle consists of those activities which identify and prioritize pertinent IRs and provide the means for satisfying them. Intelligence planning and direction is a continuous function and a command responsibility. The commander directs the intelligence effort; the intelligence officer manages this effort based upon the commander's intent, designation of PIRs, and specific guidance provided during the planning process. The intelligence planning and direction functions are—

- Requirements development.
- Requirements management.
- Collections management.
- Production management.
- Dissemination management.
- Intelligence support structure.
- Supervision of the intelligence effort.

SIGINT planning is performed in concert with overall intelligence planning. It consists of those activities that identify pertinent IRs which have been tasked to SIGINT units and then provides the means for satisfying those IRs. SIGINT planning and direction is a continuous function that requires close interaction between the G-2/S-2 and SIGINT unit planners.

SIGINT planning and direction objectives include—

- Identifying intelligence requirements tasked to SIGINT elements.
- Preparing a SIGINT operations plan, to include integral SIGINT collection, production, and dissemination plans.
- Planning and establishing the SIGINT support system (e.g., CIS, logistics).
- Issuing orders and tasking to SIGINT units.
- Supervising and coordinating the SIGINT operations.

The selection of a particular source of information or intelligence discipline to fulfill a given intelligence requirement is an important decision. SIGINT is a valuable source of information, and an effective, dynamic SIGINT operations plan must be developed to maximize the effectiveness of the SIGINT effort. With the multitude of threat signals being transmitted, the collection plan must be carefully constructed to collect and exploit enemy signals that are most likely to provide the necessary intelligence data. Additionally, the SIGINT production and dissemination plans must effectively support unique SIGINT and all-source intelligence operations requirements and operations.

a. Mission Planning

Based on the commander's PIRs and IRs, the G-2/S-2 determines those ICRs which are applicable to and have the potential to be satisfied by the organic SIGINT collection effort. The G-2/S-2 incorporates these ICRs into the overall intelligence collection plan and issues mission tasking and guidance to the RadBn OIC, ACE G-2/S-2, and other attached or supporting SIGINT units. Additionally, SIGINT taskings from the joint force commander (JFC) and supplemental taskings from DIRNSA will need to be assessed by the G-2/S-2 and incorporated if possible into MAGTF SIGINT operations (refer to USSID 4 for additional information regarding DIRNSA supplemental tasking).

b. Mission Management

SIGINT mission management is the unit commander's supervision of collection, processing, production, and dissemination efforts. Proper mission management requires centralized control of SIGINT assets at the MAGTF command element level. The OCAC (for RadBn SSUs) and the TERPES section (for VMAQ) provide this centralized control for the their respective SIGINT efforts. Collection and DF elements are usually positioned throughout the MAGTF's operations area based on the MAGTF's focus of effort, scheme of maneuver, hearability of enemy signals, and security of SIGINT units. Air SIGINT operations in support of both ACE and MAGTF requirements will be planned and incorporated in the supporting air tasking order (ATO). SIGINT unit commanders and planners must ensure that coverage is complete, that assets are gainfully employed or redirected, and that SIGINT reporting (and supporting CIS support) is effective. Collection tasks must be analyzed to determine if they can be met or if new collection or analysis efforts are required. The collection, direction finding, and analysis and production efforts must be supervised, integrated with all-source intelligence operations, and evaluated to ensure mission effectiveness.

7202. Collection

During collection, organic, attached, and supporting SIGINT elements collect and deliver information to the appropriate processing or production element (e.g., OCAC or TERPES). In some instances (e.g., immediate threat) the information will be delivered directly to the local commander for immediate action.

a. COMINT Collection

COMINT collection is performed using equipment that intercepts adversary communications signals. Simple signals (e.g., unencrypted single-channel voice) can be received by ordinary receivers. More complicated signals or those that are encrypted require more sophisticated equipment to fully exploit the signals for their intelligence value (i.e., external SIGINT processing and production centers such as the RSOCs or NSA).

Initially, a concentrated intercept search, signals analysis, and target development program is carried out to catalog the electromagnetic environment and identify the desired threat SOIs. In many cases, prior knowledge of some technical characteristics, such as in RSOC or CSSA data bases, will enhance and streamline the MAGTF's COMINT search effort. When SOIs are acquired that are readily exploitable, SIGINT collection operators prepare a gist of the transmission. Recording of the entire intercepted signal using tape recorders may also occur.

Multichannel transmissions are first divided by SIGINT operators into their component parts or separate channels and then processed channel by channel. The acquired data (e.g., logs, gists, data files, page-prints, tapes) are rapidly assessed against standing PIRs for items of immediate tactical intelligence value and reported in accordance with reporting and dissemination criteria to—

- Designated commanders.
- OCAC or TERPES production elements for detailed analysis and reporting.
- MAGTF AFC for all-source analysis and production.

b. Direction Finding

Radio DF uses electronic equipment to obtain the locations of adversary emitters by determining the direction of arrival or the time difference of arrival of the radio waves. In ideal conditions, direction finders are arrayed in a network along a predetermined baseline consisting of at least three collection and DF stations, one of which acts as net control. The DF sites must be placed carefully so that all stations can hear the target SOI and mutually support the mission.

Close coordination between collection and DF sites and the OCAC is required for a responsive DF effort. RadBn SSU DF results are then reported, either manually or via automated means, to

the OCAC for follow-on intelligence exploitation and reporting.

c. ELINT Collection and Direction Finding

Although few in numbers, the RadBn MEWSS product improvement program (PIP) (AN/MLQ-36A) provides for the automated search, acquisition, identification, and a single DF line of bearing of radars and other noncommunications emitters. Mission management, reporting, and dissemination are handled similarly to COMINT DF operations.

Additionally, in support of its strike escort mission, VMAQ elements collect ELINT information that can be used by MAGTF intelligence producers such as the MAGTF AFC and OCAC. Technical capabilities within the EA-6B's ELINT collection system allow for DF operations to occur from a single aircraft. Acquired signals are recorded and then provided to the TERPES section for postmission analysis, production, and reporting.

7203. Processing and Exploitation

The following processing and exploitation functions are used to convert collected raw information into a form suitable for SIGINT production.

a. Traffic Analysis

Traffic analysis is the study of all characteristics of communications except encrypted texts. Call signs, frequencies, times of transmission, cryptographic indicators, precedence, and message lengths are examples of these characteristics. These characteristics are called externals and are compiled and sorted primarily for the purpose of reconstructing the adversary's communication structure and organization. This information yields valuable electronic order of battle data and other information. With on-line communication encryption systems becoming widely used by potential adversaries, traffic analysis becomes an increasingly difficult function.

b. Cryptanalysis

Cryptanalysis is the study of encrypted signals, data, and texts to determine their plain language equivalents. The capability to read the adversary's encrypted communications is obviously valuable. The RadBns' limited cryptanalysis capability depends on the sophistication of the target's encryption system and the availability of specialized equipment and software resources from NSA.

c. Linguistic Analysis

Linguistic analysis is the transcription and translation of foreign language intercepts into English. This analysis starts at the collection site upon interception. Messages of considerable length require more time and are usually transcribed and translated in the OCAC. Marines are trained in a wide variety of languages for this task, but augmentation by external sources (e.g., native and/or contract linguists) may be required in order to satisfy all requirements.

d. Signal Analysis

Signal analysis consists of working with all types of signals (e.g., COMINT, ELINT, pro forma) to identify, isolate, reduce to pure form, and exploit acquired SOIs. The signal analyst must be well trained and possess the proper electronic and software support tools to be effective.

e. ELINT Analysis

The location of early warning, surveillance, and fire control radars can provide a general trace of the adversary's forward battle positions and locations of key C2 and fire control nodes and weapons systems. Medium-range and counterweapons radar identification provides order of battle information since these systems are organic to specific adversary units.

Identification and location of air defense radars provide information on the disposition of the adversary's air defense systems and their threat to strike, close air support, and assault support aircraft. Following the reporting of any I&W information to tactical decisionmakers, technical data and detailed ELINT information is forwarded to

the OCAC or to the TERPES section for further analysis, production, and reporting.

7204. Production

Production is the conversion of raw information into SIGINT product reports through the evaluation, integration, and interpretation of the information derived during the processing and exploitation effort. The results of the analysis are correlated by SIGINT analysts and reporters to form the basis for SIGINT reports. These reports are provided directly to tactical commanders when appropriate, to the G-2/S-2 for the further analysis and production of all-source intelligence, and to the staff sections for future operations planning.

SIGINT production planning and management are closely coordinated with all-source intelligence production planning and management to—

- Determine the scope, content, and format for each product.
- Develop a plan and schedule for the development of products.
- Assign priorities among the various SIGINT product requirements.
- Allocate SIGINT processing, exploitation, and production resources.
- Integrate production efforts with all-source collection and dissemination activities.

The production goal is the effective and efficient use of limited resources while focusing on established SIGINT priorities.

a. Evaluation

SIGINT analysts evaluate the raw SIGINT information to determine its pertinence to intelligence requirements. Further evaluation is made to judge the reliability and accuracy of the information and to isolate significant elements.

b. Integration

The information derived from traffic analysis, cryptanalysis, linguistic analysis, signal analysis, ELINT analysis, and radio DF must be fully integrated into a fused SIGINT product to develop a complete SIGINT picture. Concurrently, integration of SIGINT processing and production with ongoing MAGTF G-2/S-2 all-source intelligence processing and production is essential to achieve a complete, effective, and current intelligence estimate while using the strengths and results from the other intelligence disciplines to improve SIGINT operations.

c. Interpretation

The information derived from SIGINT collection is interpreted to form logical conclusions and estimates of enemy capabilities, intentions, and future actions. This step completes the translation of the raw SIGINT information into usable intelligence.

7205. Dissemination

Dissemination is the provision of SIGINT information in a timely manner and in a usable form to commanders, other decisionmakers, or all-source intelligence analysts. Because of security requirements, dissemination of COMINT information is made primarily to SIGINT and all-source intelligence production elements such as the MAGTF AFC. Proper SIGINT C2 and supporting CIS architectures that provide accurate situational awareness, along with effective IRs and tactical requirements management, enable proper dissemination.

SIGINT dissemination planning and management involves establishing dissemination priorities, stipulating dissemination and reporting criteria, selecting dissemination means, and monitoring the flow of SIGINT reporting. The ultimate dissemination goal is to deliver SIGINT products to the appropriate user in the proper form and at the right time, while concurrently preventing the dissemination of irrelevant products and avoiding information overload.

Reporting consists of providing the SIGINT products in standardized, easily usable formats needed to satisfy tasked requirements in a timely manner. The nature of the SIGINT effort requires timely reporting to effectively exploit its intelligence value. SIGINT reports generally fall into two categories, product reports and technical reports. Standardized formats are used in the preparation and transmission of these reports for speed and compatibility. As most of these formats are classified, readers should refer to USSID 300, S***IGINT Reporting***, for specific information and examples.

a. Product Reports

Product reports are prepared by all SIGINT producers for commanders, planners, and all-source intelligence analysts. A product report contains timely, accurate, thorough, relevant, and useful SIGINT information about the adversary in response to the supported commander's PIRs and IRs. Reports may be sent periodically or may be sent whenever highly perishable data is acquired in accordance with specified intelligence reporting criteria. Generally, SIGINT product reports will fall into one of three categories:

(1) SIGINT Report. In SIGINT reports, the source of information is clearly SIGINT by the content and classification markings. Such reports generally contain the SIGINT assessment along with pertinent SIGINT technical information. These reports are handled within SCI-controlled facilities and communications channels. Within a MEF, the CE, GCE, and ACE may be included in distribution for SIGINT products. Within a MEU(SOC) or special-purpose Marine air-ground task force (SPMAGTF), the CE is generally the sole recipient of these reports. When pertinent, either these reports will be fused within all-source intelligence products for further dissemination within the MAGTF or dissemination will occur via SCI courier or briefings.

(2) Non-Codeword Report. NCW reporting procedures may be used only when authorized by DIRNSA. The principal value of NCW reporting is to allow time-sensitive dissemination of critical SIGINT information to a broader audience during high tempo operations. In NCW reports, the source of information is clearly SIGINT. However, unlike standard SIGINT product reports, the NCW report is passed directly to commanders without SIGINT markings or SI security controls to allow immediate tactical use (e.g., I&W, support to targeting, support to force protection). For example, NCW reports may be passed directly from the SSU collector to other MAGTF units (e.g., an infantry battalion) via GENSER communications (usually voice message). Typically, the format for these is the standard size, activity, location, unit, time, and equipment (SALUTE) report. Specific procedures regarding NCW reporting during operations should be contained within the SIGINT appendix to annex B of the operations order.

(3) Sanitized Report. Sanitized SIGINT reports contain SIGINT information that is reported via GENSER communications means in a manner that does not reveal SIGINT as the source of the information. The level of sanitization authority allowed the MAGTF commander is established by DOD Directive TS-5105.21-M-2, ***Sensitive Compartmented Information (SCI) Security Manual, Communications Intelligence (COMINT) Policy***. Within the MAGTF, actual sanitization of SIGINT reports is generally performed by designated intelligence personnel under the guidance and supervision of the MAGTF SSO or AFC OIC. The reports are disseminated via all-source products or other GENSER intelligence reports.

b. Technical Reports

Technical reports consist of the SIGINT technical elements required by SIGINT collectors, analysts, and technical support and production agencies external to the MAGTF (e.g., call signs, frequencies, operating schedules). SIGINT technical reporting requires SCI-secure connectivity with pertinent organizations (e.g., NSA, theater RSOC, supporting CSSA) via JWICS, NSANET, or some alternate SCI communications means. Within the MAGTF, all SIGINT technical reporting is conducted by either RadBn or VMAQ's TERPES section.

7206. Utilization

SIGINT, as all intelligence, has no inherent value. Its value is realized only through its effective support of the commander's intelligence requirements or other operational requirements. Commanders, G-2/S-2s, and G-3/S-3s must continuously evaluate SIGINT operations, products, and reports for timeliness, usefulness, and overall quality and responsiveness to stated IRs. They must provide feedback to the MAGTF G-2/S-2 and SIGINT unit leaders to improve future SIGINT operations. Ultimately, SIGINT utilization provides guidance for future intelligence and SIGINT operations and management.

See appendix C, SIGINT and SCI Security Management Operations Flowchart, that summarizes the principal SIGINT planning considerations, activities, and products discussed in this chapter.

Section III. SIGINT Plans and Orders

Guidance for the conduct of SIGINT operations comes from many sources. The DIRNSA-developed USSID series are the principal SIGINT operations directives that contain policy, direction, guidance, instruction, and procedures on performing SIGINT functions in compliance with national directives and security requirements. Additionally, since MAGTFs will normally be part of a JTF or NEF, reference to joint and naval orders, guidance, and SIGINT TTPs is necessary to identify unique operating concepts and methodologies and support procedures and formats.

The MAGTF G-2/S-2 prepares SIGINT plans and orders. The intelligence operations officer coordinates the overall effort with the assistance of the SIO, other intelligence section staff officers, and the CO or OICs of organic and supporting SIGINT units. SIGINT plans and orders focus on internal MAGTF SIGINT requirements, operations, and TTP.

The SIGINT appendix will appear as appendix 2 (signals intelligence) to annex B (intelligence) in all MAGTF operations plans and orders. (See appendix D, SIGINT Appendix Format, of this manual for a recommended format for the SIGINT appendix.) It should include the following:

- Friendly forces to be utilized include—
  - Personnel augmentation requirements.
  - SIGINT units of adjacent or other theater forces and the support expected.
  - Joint force maritime component commander (JFMCC) and ATF DS SIGINT elements and CSSA available to support the landing force during amphibious operations.
  - RSOC, joint force land component commander (JFLCC), joint force air component commander (JFACC), and other component commanders or task forces capable of providing SIGINT support during JTF operations.
- Planned arrangement, employment, and use of external SIGINT support, to include any special collection, production, dissemination and CIS arrangements.
- Establishment of coordinating instructions for SIGINT operations planning and control, to include technical support expected from higher headquarters.
- MAGTF SIGINT element taskings.
- Communication and information SIGINT support.

Section IV. Execution

MAGTF SIGINT operations generally are centrally managed by the MAGTF G-2/S-2 and decentrally executed to—

- Integrate RadBn SSU and ACE VMAQ TERPES SIGINT effectively with other MAGTF and external intelligence and reconnaissance operations.
- Provide the most effective MAGTF intelligence requirements support.

The integration of RadBn SSU and VMAQ TERPES SIGINT collection, production, and dissemination plans and activities with those of other MAGTF and supporting intelligence organizations uses these limited resources and their mutual support more effectively (e.g., cueing). The MAGTF mission, commander's intent, threat operations and signals usage, concept of operations, and environmental considerations all influence the ultimate task organization, command relationship, concepts of employment, and tasks of SIGINT units. For example, they determine a decision to task-organize elements of the SSU in direct support of the GCE or rear area operations commanders. Such information is specified within annexes B, C, and K of the operations order or in a subsequent fragmentary order.

Figure 7-1 notionally depicts the following seven key aspects of these interrelated SIGINT operations.

- Task organization and command or support relationships of MAGTF SIGINT units with other MAGTF elements. RadBn SSU OCAC is collocated with the MAGTF G-2/S-2 and operates in general support of the MAGTF. VMAQ and TERPES are organic and OPCON to the ACE.
- External SIGINT units that typically support a MAGTF.
- Principal SIGINT systems employed within and in support of the MAGTF.
- Relationship of other MAGTF intelligence and reconnaissance units with SIGINT units.
- Principal communications pathways, means, and level of classification.
- Key intelligence information systems that interoperate with SIGINT systems.
- Principal SIGINT reports disseminated via the communications pathways shown.

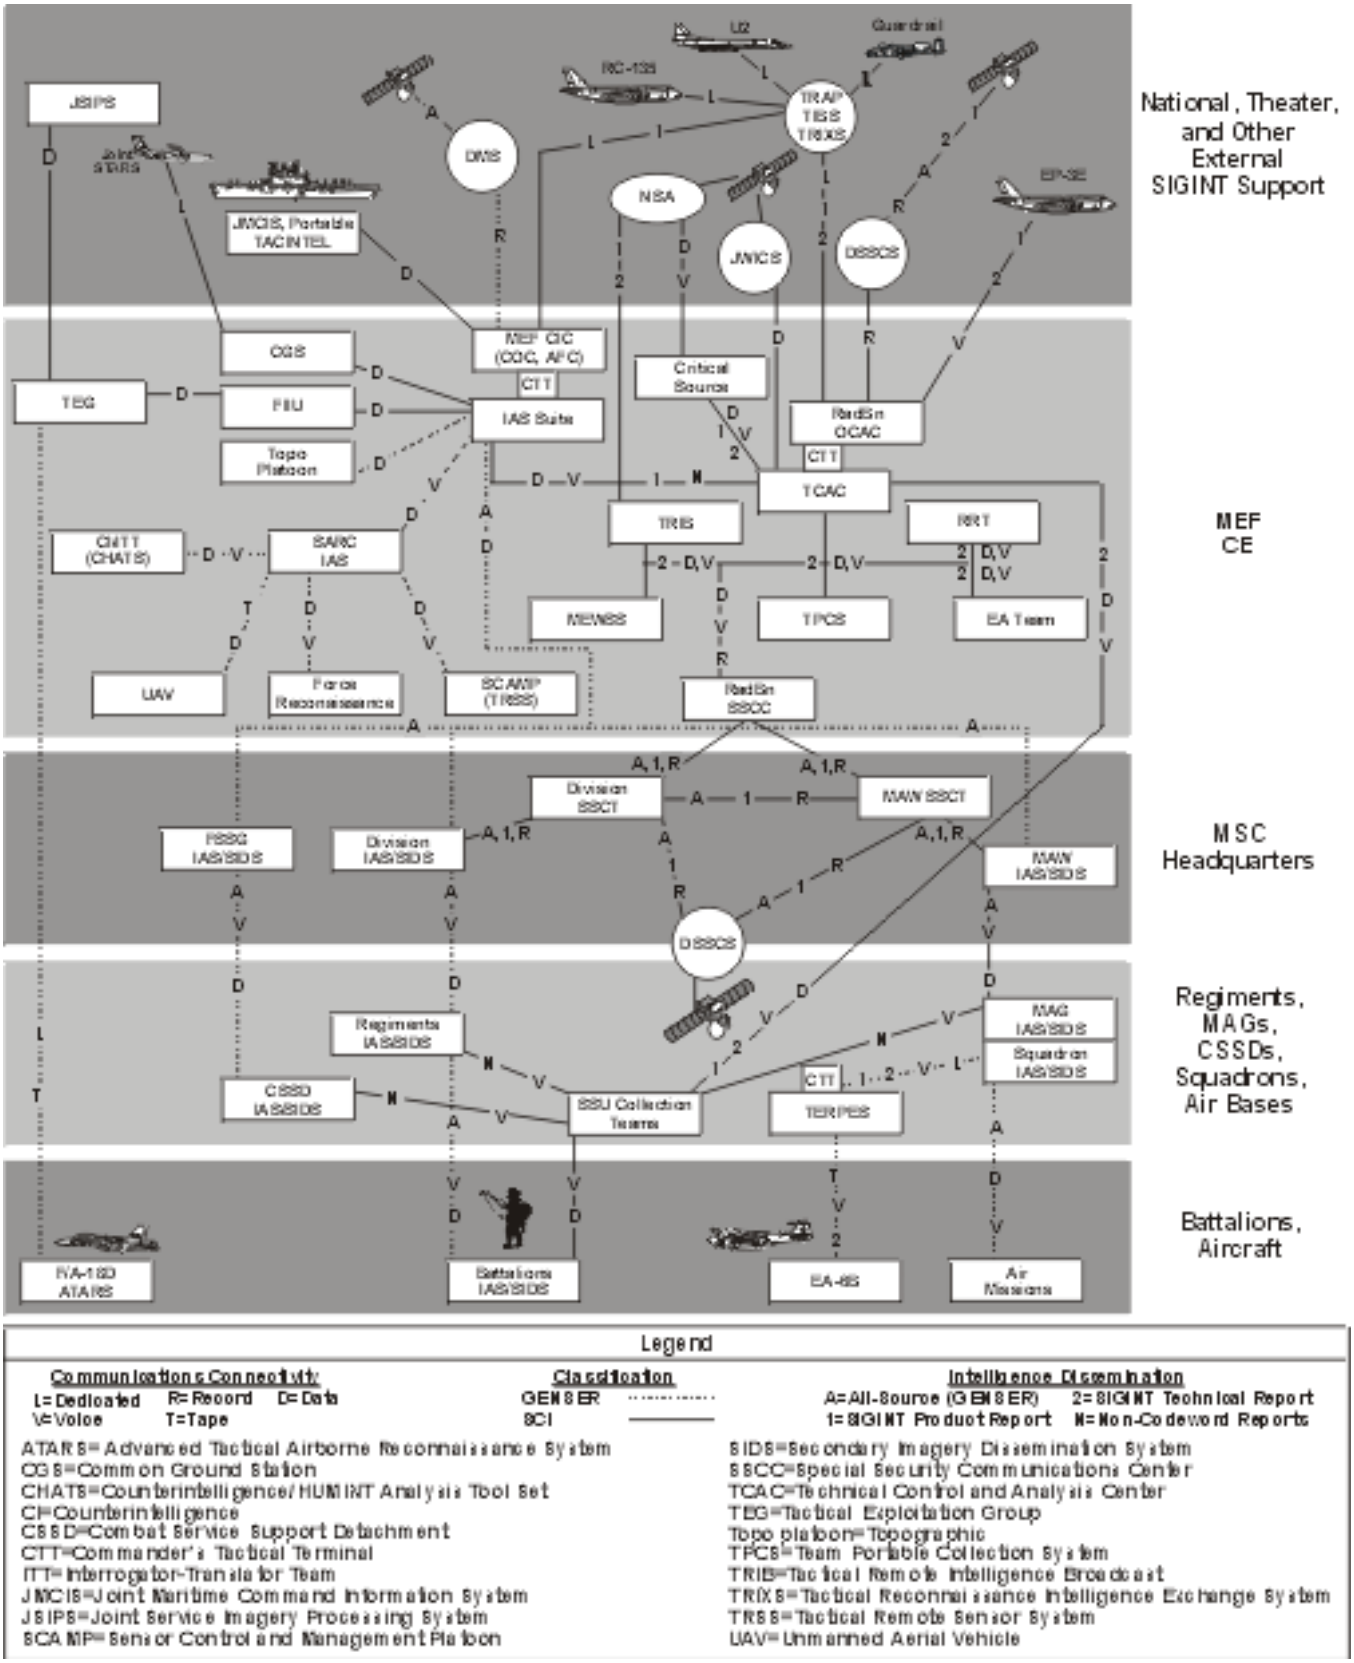

Figure 7-1. MAGTF and Supporting SIGINT Operations.

(reverse blank)

Chapter 8

Security of Sensitive Compartmented Information

SCI is classified information concerning or derived from intelligence sources, methods, or analytical processes that is required to be handled within formal access control systems established by the Director of Central Intelligence (DCI). Only intelligence and information that clearly warrant extraordinary security measures will be restricted to SCI control.

When dealing with issues involving SCI security, refer to the following publications for policy and instructions:

- **Director, Central Intelligence Directive (DCID) 1/14, *Personnel Security Standards and Procedures Governing Eligibility fo Access to Sensitive Compartmented Information.***
- **DCID 1/16, *Security Manual for Uniform Protection of Intelligence Processed in AISs and Networks*.**
- **DCID 1/21, *Physical Security Standards for Sensitive Compartmented Information Facilities*.**
- **Defense Intelligence Agency Manual (DIAM) 50-4, *Department of Defense Intelligence Information Systems (DODIIS) Information Security (INFOSEC) Program.***
- **Department of Defense Directive (DODD) 5105.21-M-1, *Sensitive Compartmented Information (SCI) Security Manual, Administrative Security*.**
- **Department of the Navy Supplement (NAVSUP) to DODD 5105.21-M-1, *SCI Administrative Security Manual*.**

These documents provide policy and guidance on—

- **SCI personnel and information security clearance procedures.**
- **SCIF and TSCIF requirements.**
- **Classification levels.**
- **Compartmentation.**
- **Decompartmentation.**
- **Sanitization.**
- **Release to foreign governments.**
- **Emergency use.**
- **Security policy and procedures for the protection of information controlled in SCI compartments.**

Safeguarding SCI is critical. Security of SCI is important as it protects not only a piece of intelligence but also its source. For these reasons, dissemination and access to SCI information and materials are restricted. However, to be worthwhile, SCI must be accessible to commanders for use in decisionmaking. SCI must be classified only to the degree necessary in the interests of security. SCI security must be applied within the context of the mission, with security needs constantly assessed and balanced against operational mission needs.

SCI security is the responsibility of the commander, who exercises this responsibility through the unit G-2/S-2. The SSO serves as the primary staff officer for day-to-day SCI security administration and management. The commander must ensure SCI is accessed only by those persons with an appropriate clearance, access approval, identified need-to-know, and appropriate SCI indoctrination. This is accomplished by carefully managing those units and persons with SCI access and the equipment and facilities used to process, disseminate, and store SCI. (Appendix C, SIGINT and SCI Security Management Operations Flowchart, summarizes the principal SCI security planning considerations, activities, and products discussed in this chapter.)

8001. Special Security Officer

The SSO serves as the command's focal point for the receipt, control, and accountability of SCI materials and the supervision of the SCI security functions of subordinate SCIFs. The SSO will be a military commissioned officer, warrant officer, or civilian (GS-9 or above). The SSO—

- Supervises the operation of the special security office and administers the SCI security program. This includes oversight of other local SCIFs under the SSO's cognizance.
- Maintains required SCI directives, regulations, manuals, and guidelines to adequately discharge SSO duties and responsibilities.
- Ensures all SCI is properly accounted for, controlled, marked, transmitted, transported, packaged, and safeguarded. Ensures all SCI is destroyed in authorized destruction facilities and in accordance with current regulations.
- Ensures SCI is disseminated only to persons authorized access with an established need-to-know.
- Provides guidance and assistance for processing SCI access and eligibility requests.
- Serves as the official channel for passing SCI access certifications.
- Conducts or otherwise manages SCI personnel, information, physical, and technical security (i.e., TEMPEST, technical surveil lance countermeasures [TSCM]) actions and procedures according to current regulations.
- Conducts SCI security briefings, indoctrinations, and debriefings; administers and maintains signed nondisclosure agreements; and performs other related personnel security actions.
- Investigates SCI security infractions, makes recommendations, prepares required reports, and initiates and supervises any necessary corrective actions.
- Conducts a continuing training and awareness program to ensure that all SCI-indoctrinated individuals are apprised of new requirements and guidelines.
- Ensures that appropriate accreditation documentation is available for each SCIF, TSCIF, and SCI system under the SSO's cognizance.

8002. Personnel Security Program

The protection of SCI is directly related to the effectiveness of the personnel security program. DCID 1/14 establishes the personnel security standards for the United States intelligence community. A mutually supporting series of program elements (e.g., need-to-know, investigation, binding contractual obligations on those granted access, security education and awareness, and individual responsibility) provides reasonable assurances against compromise of SCI by those authorized access to it.

a. Access Approval Authority

In accordance with DCID 1/14, the Director o Naval Intelligence is authorized to grant, deny, or revoke SCI access to Marines and Sailors. This responsibility is carried out through the Department of the Navy Central Adjudication Facility (DONCAF).

b. Requirements for SCI Access

DONCAF may grant an individual SCI access when the following requirements have been met.

(1) Need-to-Know is Determined. Even when approved for a specific access, the holder is expected to acquire or disseminate only that SCI essential to effectively carry out an assignment No person will have a need-to-know solely by virtue of rank, title, or position.

(2) Eligibility is Determined. DCID 1/14 provides eligibility standards for investigation and evaluation for an individual's access to SCI. A

single-scope background investigation (SSBI) conducted within the last 5 years serves as the basis for determining access approval.

(3) SCI Billet is Identified. DCI does not require the Navy to maintain an SCI billet structure. However, SSO Navy and CNSG have decided to retain the current SCI billet numbering system for accountability within the DON. SCI billets are administered by the local command SSO and reported annually to SSO Navy or CNSG as appropriate.

(4) Security Indoctrination is Completed SCI indoctrination is the instruction an individual receives prior to receiving access to an SCI systems, programs, and materials. The instruction convey the unique nature, sensitivity, and special security safeguards and practices for SCI handling, particularly the necessity to protect sensitive sources and methods.

(5) Nondisclosure Agreement is Signed. As a condition of access to SCI, individuals authorized SCI access must sign a DCI-authorized nondisclosure agreement (NDA). The NDA establishes explicit obligations on both the Government and the individual for the protection of SCI. An NDA is binding for life and cannot be revoked or waived. Failure to sign an NDA is cause for denial of SCI access.

8003. Physical Security

All SCI must be processed, used, and stored within an accredited SCIF. Accreditation is granted when the proposed facility meets the physical security standards stipulated in DCID 1/21. The SSO, DIA, is the accrediting authority for all DOD SCIFs, while NSA is the accreditation authority for all service cryptologic element SCIFs. Organizations are responsible for ensuring that SCIFs are established only when operationally required and when existing SCIFs are not adequate to support the unit's mission.

a. Sensitive Compartmented Information Facility

A SCIF is an accredited area, room, group of rooms, buildings, or installation where SCI may be stored, used, discussed, and/or electronically processed. Access to SCIFs will be controlled to preclude entry by unauthorized personnel. Non SCI-indoctrinated personnel entering a SCIF must be continuously escorted by an indoctrinated individual who is familiar with the security procedures of that SCIF. The physical security protection for a SCIF is intended to prevent as well as detect visual, acoustical, technical, and physical access by unauthorized persons.

b. Emergency Action Plans

Each accredited SCIF will establish an emergency action plan. This plan will be approved by the appropriate G-2/S-2 or SSO. The essential concern of the plan must be safety of personnel over a other factors. The plan will address—

- Physical protection of personnel working in the SCIF.
- Adequacy of fire fighting equipment and life-support equipment (e.g., oxygen and masks).
- Entrance of emergency personnel (e.g. police, medical technicians, and firemen) into a SCIF.
- Evacuation plans for persons.
- Emergency destruction and transfer procedures of classified material and equipmen in the event of—
  - Fire.
  - Loss of essential utilities.
  - Sabotage.
  - Riots.
  - Civil disorders.
  - Hostile or terrorist attack or capture.
  - Natural disasters.

c. Tactical Sensitive Compartmented Information Facility

Recognizing the need for SCIFs to support tactical operations, the DCI requires the following minimum physical security standards for a TSCIF. If the situation and time permit, these minimum standards will be improved on by using the security considerations and requirements for permanent secure facilities. (Appendix E, TSCIF Checklist, is provided as a guide when activating or deactivating a TSCIF.)

- Locate the TSCIF within the supported headquarter's defensive perimeter, preferably within its main command echelon.
- Use permanent-type facilities, if available.
- Maintain 24-hour operation under field or combat conditions.
- Establish a physical barrier around the TSCIF. Where practical, the physical barrier should be triple-strand concertina o general-purpose barbed-tape obstacle. The TSCIF approval authority determines whether proposed security measures provide adequate protection based on local threat conditions.
- Guard the TSCIF perimeter by stationing walking or fixed guards to observe the controlled area. Guards will be armed with weapons and ammunition in accordance with Marine Corps Order (MCO) 5500.6F, *Arming of Security and Law Enforcemen (LE) Personnel and the Use of Force*.
- Restrict access to the controlled area with a single gate or entrance that is guarded continuously.
- Maintain an access list. Only those people whose names appear on the list will be allowed access to the TSCIF.
- Staff the TSCIF with sufficient personnel as determined by the on-site SSO or G-2/S-2 based on the local threat conditions.
- Keep emergency destruction and evacuation plans current.
- Store SCI material in lockable containers when not in use.
- Establish and maintain communications with local security or emergency reaction forces, if possible.
- Conduct an inspection of the vacated TSCIF area. The SSO or G-2/S-2 ensures SCI materials are not inadvertently left behind when the TSCIF displaces.
- Coordinate planning with the unit's headquarters commandant, who is responsible for providing TSCIF guard personnel, communication with command post guard forces, emergency personnel reaction forces, and internal reaction forces.

d. Mobile Tactical Sensitive Compartmented Information Facility

Mobile TSCIF requirements are as follows:

- Maintain a 24-hour operation and staff the TSCIF with sufficient personnel as determined by the on-site SSO or G-2/S-2 based on the local threat conditions.
- Incorporate external physical security measures into the perimeter defense plans for the immediate area in which the mobile TSCIF is located. (A physical barrier is not required as a prerequisite to establish a mobile TSCIF.)
- Use Marines performing the day-to-day operations of the TSCIF to control external physical security.
- Establish and maintain communication with backup guard forces, if possible.
- Incorporate incendiary methods in emergency destruction plans to ensure total destruction of SCI material during emergency situations.
- Adhere to the following restrictions when using a rigid-sided shelter or portable van.
  - Mount the shelter to a vehicle so that the shelter can move on short notice.
  - Affix a General Services Administration (GSA)-approved security container permanently within the shelter. Protect the lock combination to the level of security of the material stored therein.

- Control the entrance to the mobile TSCIF with SCI-indoctrinated Marines on duty within the shelter.
- Limit entrance to the mobile TSCIF to SCI-indoctrinated personnel.
- Store classified material within the locked GSA container and secure the shelter' exterior entrance during redeployment.

- Adhere to the following restrictions when using a mobile TSCIF for a soft-sided vehicle or man-portable system.
  - Protect SCI material in an opaque container (i.e., leather pouch, metal storage box, or other suitable container that prevents unauthorized viewing).
  - Keep this container in the physical possession of an SCI-indoctrinated person.

- Limit the quantity of SCI material permitted within the mobile TSCIF to that which is absolutely essential to sustain the mission. Employ stringent security arrangements to ensure that the quantity of SCI material is not allowed to accumulate more than is absolutely necessary.

e. Tactical Sensitive Compartmented Information Facility Accreditation

The accreditation process consists of three steps, each requiring a message to be sent to the cognizant approval authority (see NAVSUP to DODD 5105.21-M-1). Approval authorities vary with respect to information and formats required. When requesting TSCIF authorization and accreditation, use the current reference from the cognizant authority. The following reports and messages are prepared by the unit SSO or G-2/S-2.

(1) Concept of Operations. A message that outlines the who, what, when, where, and why for the TSCIF and identifies supporting security, administrative, and point of contact information.

(2) TSCIF Activation Report. A report sent to the approval authority upon commencement o TSCIF operations.

(3) TSCIF Deactivation Report. A report sent to the approval authority when the TSCIF has ceased operations and has been certified to be free of SCI material.

8004. Information Systems Security

All SCIF intelligence and information systems used for processing, storing, and conveying intelligence and/or SIGINT information must be accredited prior to operating. The DON approving authority for SCIF intelligence systems is the Office of Naval Intelligence (ONI-54) in accordance with DIAM 50-4. The cognizant DON approving authority for SCIF resident cryptologic systems is CNSG (N1).

The SSO is responsible to the G-2/S-2 for overall management and administration of the unit's SCI security program and for SCIF security. The unit's information system security manager (ISSM) and the information system security officer (ISSO) complement the SSO and are accountable for the SCIF-resident information systems The ISSM or ISSO will help ensure new and changed information systems meet all security requirements. These individuals coordinate the approval of new or changed systems with the appropriate DON approving authority. Normally, the ISSM and ISSO are the principal interface between the approving authority and the local command.

Chapter 9

Training

The policies, standards, and procedures for the conduct of SIGINT training as well as the assignment of responsibilities to ensure adequate and responsive training are spelled out in DODD 5210.70, *DOD Cryptologic Training.* Additionally, MCO 1510.50A, *Individual Training Standards (ITS) System for the Signals Intelligence Ground Electronic Warfare Occupational Field (OccFld)*, provides a detailed description (by rank and MOS) of tasks SIGINT Marines must be capable of performing.

9001. Military Occupational Speciality Training

Training for the SIGINT Marine focuses on building, maintaining, and enhancing the technical skills required to be MOS proficient.

a. Entry-Level Training

The foundation for all SIGINT Marine training is the entry-level training. Due to its highly technical nature, this OccFld possesses some of the longest MOS entry-level training pipelines. The following paragraphs briefly describe these pipelines.

(1) 0206 Basic SIGINT. Following The Basic School, all SIGINT-designated lieutenants are sent to the Cryptologic Division Officers Course (CDOC), Corry Field, Pensacola, Florida. Following CDOC, all 0206 lieutenants are ordered to one of the two RadBns to develop and enhance their SIGINT skills.

(2) 7588 Electronic Warfare Officer. The initial, formal EW training for air EW lieutenants is the Joint Electronic Warfare School, Pensacola Florida. The course focuses on basic radar theory, friendly and threat integrated air defense system (IADS), naval forces organization and capabilities, and the application of EW.

Following the Joint Electronic Warfare School, 7588 lieutenants receive specialized training with the Fleet Replacement Squadron (VAQ-129), Whidbey Island, Washington. This 9-month course provides instruction and training on the EA-6B aircraft operations and systems and on threat IADS aircraft and shipping. Additionally all 7588 electronic warfare officers obtain Naval Air Training and Operating Procedures Standardization (NATOPS) program qualification in the EA-6B.

(3) 2621 Manual Morse Intercept Operator. Manual Morse training begins with Morse code training at Ft. Huachuca, Arizona. Upon graduation, the new manual Morse intercept operator reports to Corry Field, Pensacola, Florida, for the Communication Signals Collection and Processing (450) Course.

(4) 2631 ELINT Intercept Operator or Analyst. Basic ELINT training is provided by the Cryptologic Technician Course, Corry Field, Pensacola, Florida. Marines assigned to the VMAQ TERPES section also attend the TERPES Operator Course, Navy and Marine Corps Intelligence Training Center, Dam Neck, Virginia.

(5) 2651 Special Intelligence Communicator. Training in SI communications, data communications, networks, and system security is provided in the Cryptologic Technician "O" Course, Corry Field, Pensacola, Florida.

(6) 267X Cryptologic Linguist. The cryptologic linguist has the longest initial training track of any ground MOS. Training begins with basic language training at the Defense Language Institute (DLI), Monterey, California, for a period of 47 to 63 weeks, depending on the language and

student's ability. Following graduation from DLI, the basic linguist will report to Goodfellow AFB, Texas, for cryptologic linguist specialist training.

(7) 2629 SIGINT Analyst. Upon completion of their initial tour, many 2621's, and some 2631's, and 267X's will attend the Fleet Analysis and Reporting Course, Goodfellow AFB, Texas, for additional training to qualify for MOS 2629, SIGINT analyst.

b. SIGINT Skill Progression Training

SIGINT Marines have a wealth of resident and nonresident training opportunities to refine, maintain, or enhance their skills. These programs are announced by HQMC and include—

- NSA Director's Fellowship Program for field grade officers.
- Junior Officer Cryptologic Career Program for company grade officers.
- Middle Enlisted Cryptologic Career Advancement Program for SNCOs.
- Military Intern SIGINT Analyst Program for SNCOs and NCOs.
- Military ELINT Signals Analyst Program for SNCOs and NCOs.
- Marine Corps Cryptologic Computer Administration Program for enlisted Marines.
- Various military linguist programs.

9002. Functional Training

Functional SIGINT training focuses on ensuring Marines in all elements of the MAGTF are aware of SIGINT contributions and the corresponding SIGINT or EW threat from our adversaries.

a. SIGINT Marines

Functional training educates SIGINT Marines on all-source intelligence operations within the MAGTF, naval forces, and JTFs. SIGINT Marines participate in exercises to learn operational intelligence requirements; the interaction between commanders and staffs and MAGTF units and intelligence sections; and the capabilities, limitations, and operational support methodologies within MAGTF and other units. During exercises, SIGINT Marines interact with the G-3/S-3 and G-6/S-6 to refine coordination requirements and improve intelligence flow during actual operations.

b. SIGINT Training of Non-SIGINT Marines

Non-SIGINT Marines are trained in the capabilities and limitations of Marine, Navy, JTF, theater, and national SIGINT systems that support MAGTF operations. Equal time should be spen training these Marines on the capabilities and limitations of the adversary's SIGINT or EW systems and on individual and force protection tactics and techniques. To improve mutual understanding and eliminate misconceptions, the unique security restrictions required when dealing with SIGINT information should also be explained to and practiced by non-SIGINT Marines.

9003. Exercises

SIGINT operations in exercises are closely controlled. The same security precautions and controls are required for both the real world and exercises. USSID 56, *Exercise SIGINT*, provides guidance on obtaining and using SIGINT during exercises.

Exercise SIGINT provides commanders, staffs and units with experience in SIGINT operations, information, rules, communications, and personnel. Exercise SIGINT operations may be conducted with or without an opposition force. Care should be taken during exercises to present a realistic picture of what SIGINT systems can provide to avoid creating false expectations.

If an opposition force does not participate, exercise SIGINT may be scripted or preplanned (e.g., staff exercise [STAFFEX] or a command post exercise [CPX]). Use of scripted SIGINT in an exercise must be requested and approved by the appropriate agency well in advance of the exercise. This will allow time to script the exercise

SIGINT necessary to realistically support the scenario. Exercise planners and exercise SIGINT scripters must coordinate to ensure the SIGIN information flow is realistic. All security requirements must be maintained throughout the exercise (e.g., TSCIF activation and SCI-handling procedures).

Exercise SIGINT operations may be conducted against an opposition force (e.g., during a MAGTF field exercise). This provides more realistic training for the SIGINT element and SIGINT users. Depending on the level of the exercise, the use of simulators and national systems may be requested to add realism and enhance training These assets must be requested well in advance of the exercise and approved by the appropriate agency described in the J-TENS manual.

9004. Operational Training Objectives

The major objective for SIGINT operations training is exercising SIGINT operations in a realistic tactical environment with all elements of the MAGTF.

a. SIGINT Organizations

RadBns and VMAQs should—

- Train unit leaders, planners, and supervisory personnel to—
  - Plan and direct, process and exploit, produce, disseminate, and use unique SIGINT and integrated all-source intelligence.
  - Plan and integrate SIGINT operations with multifunctional staff operations.
  - Conduct SIGINT operations.
- Train SIGINT operators in SIGINT—
  - Operations.
  - Systems.
  - Equipment.
  - TTP.
  - Supporting operations (i.e., CIS, logistics, and intelligence).

b. G-2/S-2 and Intelligence Personnel

Intelligence personnel must be able to—

- Understand the capabilities and limitations of SIGINT collection operations and the planning, integration, coordination, and execution of SIGINT collection with multidiscipline intelligence and reconnaissance collection operations.
- Understand the capabilities and limitations of SIGINT production operations and the planning, integration, coordination, and execution of SIGINT production with all-source intelligence production operations.
- Understand the capabilities and limitations of SIGINT dissemination operations (e.g. planning, integration, coordination, and execution of routine and time-sensitive SIGINT dissemination) and the requirements, establishment, and integration of unique SIGINT and multiuse CIS architectures.

c. G-3/S-3 and Maneuver and Fires Personnel

Operations, maneuver, and fires personnel should be able to—

- Plan, coordinate, and conduct effective MAGTF SIGINT, EW, and CIS operations.
- Plan, coordinate, and conduct insertion and extraction methods.
- Site and coordinate SIGINT collection and DF teams with supporting SIGINT elements, G-2/S-2, and subordinate commanders.
- Coordinate SIGINT operations with MAGTF and subordinate units' future and current operations centers and fire support coordination centers.
- Disseminate and use SIGINT and other SCI information.

d. G-4/S-4 and Combat Service Support Personnel

Logistics and CSS personnel should understand SIGINT units' unique CSS requirements (particularly electronic maintenance and unique consumables such as batteries).

e. G-6/S-6 and Communications and Information Systems Personnel

CIS personnel must be able to plan, coordinate and integrate SIGINT CIS requirements within MAGTF and supporting CIS plans and operations.

f. Headquarters Commandant

Headquarters commandant personnel must be able to understand, plan, and provide for the SIGINT units' security requirements (particularly those associated with TSCIFs and mobile SIGINT SCIFs).

Appendix A

Radio Battalion SIGINT Support Unit Checklist

The following checklist is provided as a guide to assist the radio battalion (RadBn) SIGINT support unit (SSU) officer in charge (OIC) conduc operations. Depending on the mission, location and duration of an operation, some items may not be applicable.

Planning Stage

- ❑ **Coordinate with the RadBn S-3 to—**
  - ❍ **Determine exact mission and tasking of the detachment and the authority and command relationship.**
  - ❍ **Review all messages related to deployment and composition of the detachment.**
  - ❍ **Ensure S-3 tasks companies or sections to provide required personnel to fill detachment table of organization (T/O) line numbers.**
  - ❍ **Request assignment of RadBn SIGINT address and producer designator digraph, if necessary.**
  - ❍ **Verify formats and instructions for required reports.**
  - ❍ **Determine if area clearances and clearance certifications are necessary and request special security officer (SSO) take appropriate action.**
  - ❍ **Review pertinent orders and instructions of the supported unit.**
  - ❍ **Identify and arrange for special training and operational requirements.**
- ❑ **Coordinate with the following supported command—**
  - ❍ **G-2/S-2 intelligence operations officer to determine initial intelligence collection, production, and dissemination requirements and current intelligence estimate.**
  - ❍ **G-2/S-2 intelligence operations officer to determine time constraints for submission of input to appendix 2 to annex B of the operations order.**
  - ❍ **G-2/S-2 all-source fusion center OIC to determine plans and integration of intelligence and SIGINT production activities.**
  - ❍ **G-2/S-2 dissemination officer for a list of SIGINT products recipients, appropriate report formats, and routine and time-sensitive communications and information systems (CIS) plans.**
  - ❍ **G-2/S-2 intelligence operations officer and G-4/S-4 for supply and logistics requirements to be provided by supported command (e.g., electronic maintenance and consumables such as batteries; meals, ready to eat; maps; and fuel).**
  - ❍ **G-3/S-3 electronic warfare officer for electronic attack (EA) requirements and capabilities and input to appendix 3 to annex C of the operations order.**
  - ❍ **G-2/S-2 operations officer and G-6/S-6 to address requirements for communications support (e.g., secure and unclassified local area network [LAN] access, equipment).**
  - ❍ **G-3/S-3 to establish liaison teams with supported unit's subordinate elements if necessary.**
  - ❍ **Command security manager, G-2/S-2, and G-3/S-3 for force protection and communications security monitoring requirements and plans.**
- ❑ **Develop and publish a training schedule in coordination with the RadBn S-3 and supported unit's intelligence officer.**

- ❑ Request courier cards from RadBn SSO for appropriate detachment personnel.
- ❑ Coordinate collection and analytical and production requirements with the operations control and analysis (OCA) element to—
  - ○ Ensure the detachment analytical and production team knows the technical aspects of the operations area.
  - ○ Ensure the analytical and production team has a current technical support package; request an update if required (i.e., hardcopy, electronic copy).
  - ○ Ensure SIGINT position designators for equipment are current; prepare and issue required SIGINT resource status report (RSR).
  - ○ Ensure the National Security Agency (NSA) or the pertinent regional security operations center or cryptologic shore support activity provides a current technical briefing on targets in the area of operations.
- ❑ Coordinate transportation requirements with RadBn S-3, S-4, and supported unit.
- ❑ Coordinate embarkation requirements with RadBn S-4 and supported unit to—
  - ○ Review current embarkation orders.
  - ○ Complete embarkation forms (e.g., Tactical Cargo Manifest Declaration, 1387-2, 1348-1).
  - ○ Review current inbound and outbound agricultural restrictions on vehicles.
  - ○ Assemble complete embarkation kit with guidelines for use upon departure.
  - ○ Request table of equipment (T/E) items for detachment.
- ❑ Coordinate communications and information requirements with RadBn S-6 and supported unit intelligence officer and CIS officer to—
  - ○ Determine circuit request requirement.
  - ○ Determine telecommunications service request (TSR) requirement.
  - ○ Determine frequency and call sign requirements and request communications-electronics operating instructions.
  - ○ Request special intelligence (SI) routing indicator and plain language address assignments.
  - ○ Determine communications security materials system (CMS) requirements and request that the CMS custodian have material available for issue.
  - ○ Designate an SSO CMS custodian.
  - ○ Determine TEMPEST inspections and automated information systems accreditation requirements.
  - ○ Determine cryptographic hardware and keying material requirements and procedures with all communication elements.
- ❑ Ensure all personnel are qualified with T/O weapons and arrange for battlesight zero (BZO) firing as necessary.

Predeployment Stage

- ❑ Audit health records to—
  - ○ Determine inoculations required and arrange for required shots with the corpsman.
  - ○ Determine if detachment members or members of their families are undergoing extensive outpatient care, with an indefinite prognosis.
  - ○ Confirm and record blood types.
  - ○ Ensure all personnel requiring eyeglasses have two pair. Also ensure they have optical inserts for gas masks.
  - ○ Ensure detachment members meet class I or II dental readiness.
  - ○ Arrange for block pickup of health and dental records.

- ❑ Coordinate legal affairs to—
  - ○ Inform personnel of advisability of wills and procedures for obtaining them.
  - ○ Inform personnel of powers of attorney and procedures for obtaining them.
- ❑ Arrange for storage of privately owned vehicles and personal effects.
- ❑ Arrange for mail handling.
- ❑ Coordinate pay matters to—
  - ○ Conduct personal financial record audit.
  - ○ Prepare savings and other allotments.
- ❑ Coordinate administrative matters to—
  - ○ Verify accuracy of record of emergency data.
  - ○ Ensure identification cards are current and have proper Geneva Convention category information.
  - ○ Ensure personnel have current identification (ID) tags.
  - ○ Audit and update officer qualification records and enlisted service record books.
  - ○ Complete change of reporting senior fitness reports, fitness report roughs, and proficiency and conduct marks.
- ❑ Coordinate clothing inspection and requirements to—
  - ○ Ensure personnel have appropriate serviceable uniforms for all destinations.
  - ○ Ensure personnel have appropriate civilian attire in accordance with local military customs of country(ies) to be visited.
  - ○ Ensure temporary issue requirements draw includes the proper sizes and is coordinated through the RadBn S-4 and supported unit.
- ❑ Ensure baggage is appropriate and of sturdy construction.
- ❑ Ensure personnel know customs requirements of locations to be visited.
- ❑ Prepare government transportation request.
- ❑ Prepare military transportation authorization.
- ❑ Conduct the following:
  - ○ Family services deployment briefing for all SSU and family members.
  - ○ Red Cross brief.
  - ○ Navy and Marine Corps Relief brief (to include preauthorized emergency loan applications).
  - ○ Religious services brief.
  - ○ Family services brief.
  - ○ Key spouses brief.
- ❑ Assemble assigned T/E equipment required for deployment to—
  - ○ Perform operational check of equipment.
  - ○ Complete limited technical inspection (LTI) on all equipment.
  - ○ Perform acceptance inspections on all temp-loan equipment.
  - ○ Check the date of last calibration, if applicable.
- ❑ Arrange for draw or transfer of CMS material.
- ❑ Receive CMS custodial briefing from CMS custodian.
- ❑ Receive security requirements and emergency destruction briefing from SSO.
- ❑ Conduct training in accordance with established detachment training schedule.
- ❑ Coordinate with the RadBn SSO and classified materials control officer to—
  - ○ Designate a detachment classified material secondary control point and custodian.

- ○ Ensure required single-scope background investigation periodic reviews are initiated on those detachment personnel identified as needing updates.
- ○ Request sensitive compartmented information (SCI) clearance certification on all detachment personnel be forwarded to cognizant units and other organizations as necessary.

❑ Coordinate with the RadBn adjutant or S-1 to—

- ○ Draw record books.
- ○ Pick up orders.
- ○ Establish report criteria.
- ○ Arrange for administrative and legal briefs.
- ○ Arrange for detachment Uniform Code of Military Justice and code of conduct briefings.

❑ Coordinate with RadBn SSO to—

- ○ Confirm security requirements.
- ○ Pick up courier cards for specified personnel.
- ○ Receive area intelligence briefs to include customs, politics, religion, and standards of personal conduct.
- ○ Receive counterintelligence area threat briefs.
- ○ Ensure all required personnel receive appropriate special access indoctrination(s).
- ○ Transfer necessary technical material from SSO and OCA classified material control center accounts.

❑ Coordinate with RadBn S-3 to—

- ○ Establish SIGINT operations report criteria.
- ○ Determine topographic and map requirements and request allowance from OCA or the supported unit.
- ○ Request preparation of appropriate cryptologic technical kits from NSA or the supporting cryptologic shore support activity.

❑ Coordinate with RadBn S-4 supply to establish fiscal account job order numbers and sign the consolidated memorandum receipt.

❑ Coordinate with RadBn S-4 electronic maintenance to—

- ○ Establish equipment maintenance procedures.
- ○ Establish electronic maintenance support and prepare pre-expend bin support block.
- ○ Ensure that all equipment receives a predeployment LTI.
- ○ Ensure skeleton record jackets are prepared for all equipment.

❑ Coordinate with RadBn S-4 motor transport and engineer to—

- ○ Establish equipment maintenance procedures.
- ○ Establish motor transport and engineer support.
- ○ Ensure skeleton record jackets are prepared for all vehicles.

❑ Coordinate with RadBn S-4 ordnance officer to—

- ○ Determine weapon requirements and other ordnance needs.
- ○ Obtain proper storage boxes for the transport of weapons.
- ○ Draw weapons.
- ○ Conduct necessary inspections.
- ○ Conduct daily sight counts.

- ○ Determine ammunition and pyrotechnic training requirements during deployment.

- ❑ Coordinate with RadBn S-4 embarkation officer to—
  - ○ Receive embarkation package.
  - ○ Determine dunnage requirements.
- ❑ Draw equipment and sign for gear assigned to detachment.
- ❑ Receive medical brief from battalion medical personnel.
- ❑ Contact special services officer for recreation items.
- ❑ Publish the final—
  - ○ Detachment T/O and T/E.
  - ○ Roster of personnel.
  - ○ Dependent point-of-contact roster.
  - ○ Equipment and uniforms required.
  - ○ Detachment training schedule.
  - ○ Detachment operations order.
- ❑ Palletize or combat load supplies and equipment.
- ❑ Coordinate embarkation of personnel and equipment with S-4 of supported unit.
- ❑ Stage for embarkation.

Deployment

- ❑ Coordinate with G-2/3 and S-2/3 for initial location of combat operations center, combat intelligence center, and collection direction finding (DF) and EA teams.
- ❑ Continue coordination of collection and DF team and radio reconnaissance team locations with G-2/S-2 collections officer and G-3/S-3. Include updates for inserts, extract times, and methods.
- ❑ Coordinate with G-2/S-2 intelligence operations officer for inputs and presentation for intelligence estimate, concept of operations, and intelligence operations plans briefings.
- ❑ Submit the following required reports and messages:
  - ○ Activation report and deactivation report to RadBn S-3 and supported unit G-2/S-2.
  - ○ Circuit activation report to RadBn S-6 and supported unit G-6/S-6.
  - ○ Administrative reports to RadBn S-1.
  - ○ CMS destruction reports to SSO or CMS.
  - ○ Circuit deactivation report to RadBn S-6 and supported unit G-6/S-6.
  - ○ Transportation request to RadBn and supported unit G-4/S-4.
  - ○ Required analysis and technical reports to OCA and supported unit G-2/S-2. (RSR to NSA upon activation and deactivation.)
  - ○ Tactical SCI facility activation and deactivation reports to Commander, Naval Security Group, supported unit SSO, and others as appropriate.
- ❑ Prepare and distribute required reports to the supported commander.
- ❑ Send deactivation message.

Postdeployment

- ❑ Turn in weapons and classified material immediately upon return.
- ❑ Participate in supported unit operations debriefings as required. Debrief with RadBn commanding officer and S-3 on the first working day after return.
- ❑ Coordinate with RadBn adjutant, S-1, S-3, and S-4 to—
  - ○ Return record books to S-1.
  - ○ Return medical and dental records.

- ❍ Terminate temporary additional duty (TAD) orders.
- ❍ Prepare and submit performance evaluation reports and proficiency and conduct marks as required for the TAD period.
- ❍ Notify mail clerk to stop forwarding mail.
- ❍ Return technical material to the OCA platoon.

❑ Return CMS material to CMS custodian within 48 hours of return.

❑ Return courier cards to SSO.

❑ Prepare equipment for postdeployment LTI.

❑ Ensure proper maintenance is conducted on equipment prior to returning to respective companies or sections.

❑ Turn in equipment on equipment repair orders and note any equipment damage or problems.

❑ Settle fiscal account.

❑ Submit an after action report within 20 days of return (or as directed) to the supported unit G-2/S-2, G-3/S-3, and RadBn S-3.

❑ Disband detachment.

❑ Prepare award recommendations on deserving personnel.

❑ Recommend necessary changes to unit SOPs and coordinate with the RadBn and supported unit staff.

Appendix B

Marine Corps SIGINT Equipment

Radio battalions (RadBns) and Marine tactical electronic warfare squadrons (VMAQs) use unique specialized equipment for the search, detection, identification, processing and exploitation of enemy signals of interest (SOIs), and the subsequent production and dissemination of SIGINT products. The following sections describe the primary SIGINT equipment in the inventory of the RadBns and VMAQs.

Section I. Radio Battalion SIGINT Equipment

AN/ULQ-19(V)2 Electronic Attack Set

The AN/ULQ-19(V)2 electronic attack (EA) set (figure B-1) provides the capability to conduct spot or sweep jamming of single-channel, encrypted or unencrypted, voice or data signals operating in the standard military frequency range of 20-79.975 MHz from selected mobile platforms (e.g., high mobility, multipurpose wheeled vehicles [HMMWVs], mobile electronic warfare support system [MEWSS], helicopters). In addition, it can provide up to four channels of high-power VHF voice and/or data communications when not being used as a jamming system. When employed as a tactical, general-purpose, low-VHF jamming system, it has a 250-watt radio frequency linear amplifier that produces a nominal 200 watts of effective radiated power (ERP) using a standard omnidirectional whip antenna. To provide required jamming, the system must be employed and operated from a location with an unobstructed signal line of sight to the target enemy's communications transceiver.

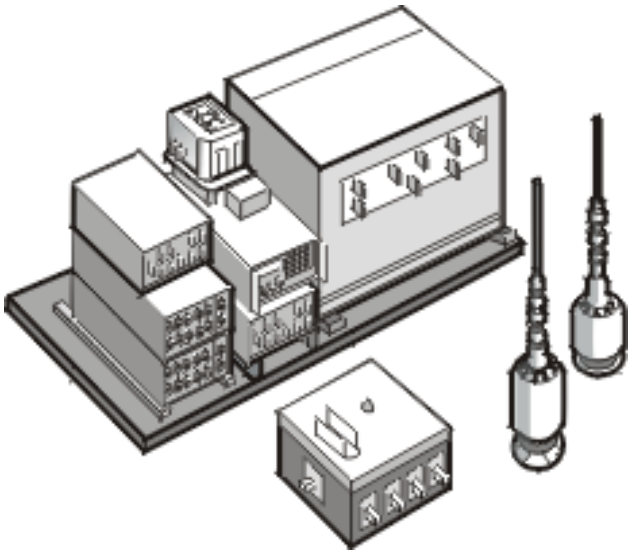

Figure B-1. AN/ULQ-19(V)2.

AN/MLQ-36 Mobile Electronic Warfare Support System

The AN/MLQ-36 MEWSS provides a multifunctional capability that gives SIGINT electronic warfare (EW) operators limited armor protection (figure B-2). This equipment is ideally suited to provide SIGINT EW support for highly mobile mechanized and military operations in urban terrain where maneuver and/or armor protection is critical. MEWSS comprises a signals intercept system, a radio direction finding (DF) system, an EA system, a secure communications system, and an intercom system installed in a logistics variant of the light armored vehicle (LAV)-25. Electronic warfare support (ES) activities are accomplished through the use of two WJ-8618B(S1) acquisition receivers and the WJ-32850 MANTIS DF system. EA activities are conducted with the AN/ULQ-l9(V) electronic attack set.

Figure B-2. AN/MLQ-36.

AN/MLQ-36A Mobile Electronic Warfare Support System Product Improvement Program

The mobile electronic warfare support system product improvement program (MEWSS-PIP) is an advanced SIGINT/EW system integrated into an LAV (figure B-3). The MEWSS-PIP provides a total replacement of the EW mission equipment now fielded in the AN/MLQ-36 MEWSS. It provides the ground commander with a mobile SIGINT/EW system capable of operating in a variety of tactical situations. The primary mission of the MEWSS-PIP is to provide intercept, collection, automated DF, and EA against threat modern communications and noncommunications emitters across a broad frequency range. It is a multiservice, open-systems architecture developed by the Marine Corps and the Army that incorporates elements of the Army's intelligence and electronic warfare common sensor (IEWCS) system. This system enhances interoperability through cooperative engagement, data sharing, and precision location. Initial operational capability is scheduled for fourth quarter, fiscal year 1999.

Figure B-3. AN/MLQ-36A.

AN/PRD-12 Direction Finder Set

The AN/PRD-12 is a tactical, man-transportable system that provides search, intercept, and DF on communications signals in the HF/VHF/UHF bands (figure B-4). Up to four PRD-12 stations can be networked, providing DF data to a mission control station via radio link with single-channel ground and airborne radio system (SINCGARS) equipment. Each station has the ability to function as the net control station. When stations are networked, they provide target emitter position data to mission control via voice link. A complete station can be relocated rapidly, optimizing its use in forward areas with combat units.

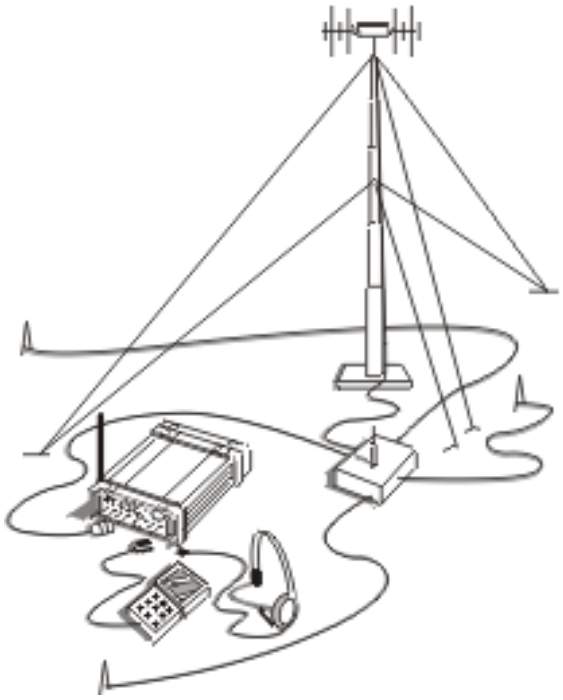

Figure B-4. AN/PRD-12.

AN/MSC-63A Communications Central

The AN/MSC-63A is a shelterized communications switch that provides a secure semiautomated data communications switch and terminals for the processing of general service (GENSER) or defense special security communications system (DSSCS) sensitive compartmented information (SCI) record message traffic. See figure B-5. There is one AN/MSC-63A with each Marine division and Marine aircraft wing special security communications team, and three AN/MSC-63A's with each RadBn. The system consists of three functional subsystems: shelter and auxiliary support subsystem, the communications subsystem, and the data processing subsystem. See figure B-6. The AN/MSC-63A is fully compatible with the Army's AN/TYC-39.

Figure B-5. AN/MSC-63A.

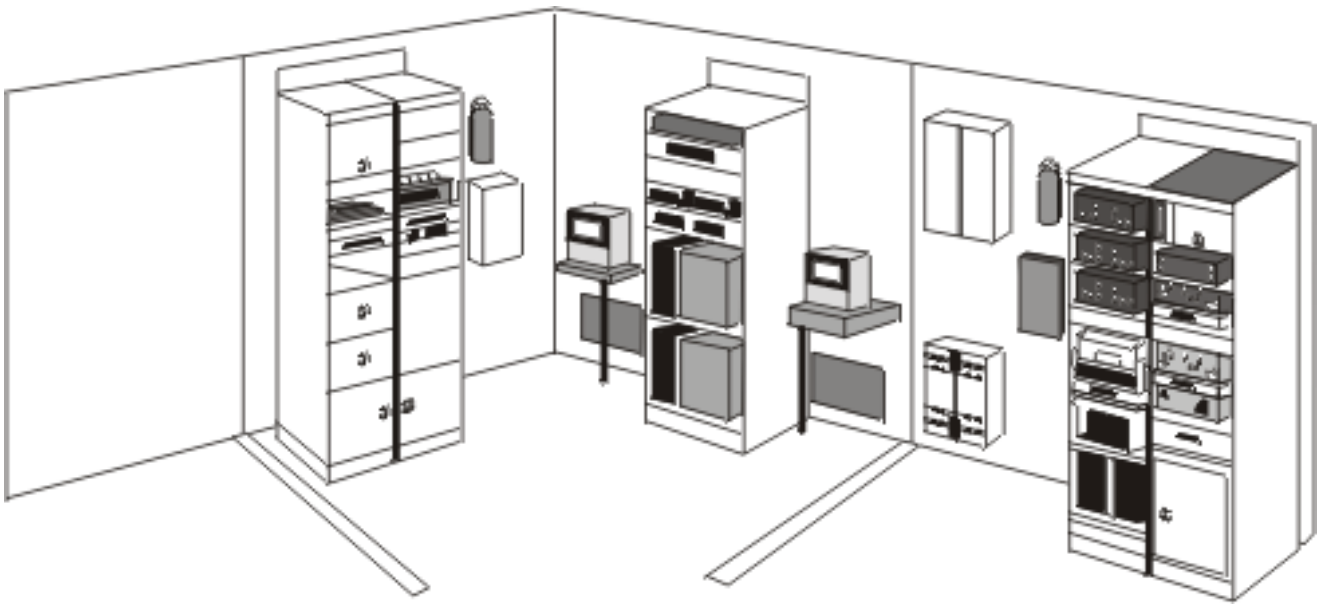

Figure B-6. AN/MSC-63A (interior view).

AN/TSQ-130(V)2/(V)5 Technical Control and Analysis Center

The AN/TSQ-130(V)2/(V)5 technical control and analysis center (TCAC) is an all-weather, tactical, transportable, SIGINT-processing, analysis and reporting system installed in a large, self-contained, modified S-280G shelter. TCAC is the primary system used by the RadBn SIGINT support unit. It is capable of performing semiautomated-SIGINT collection management, data base maintenance, analysis, technical and tactical reporting, and SIGINT technical control of forward deployed RadBn elements or teams. The (V)2 is the baseline system, while the (V)5 has upgraded communications capabilities. See figure B-7 for a notional TCAC concept of employment.

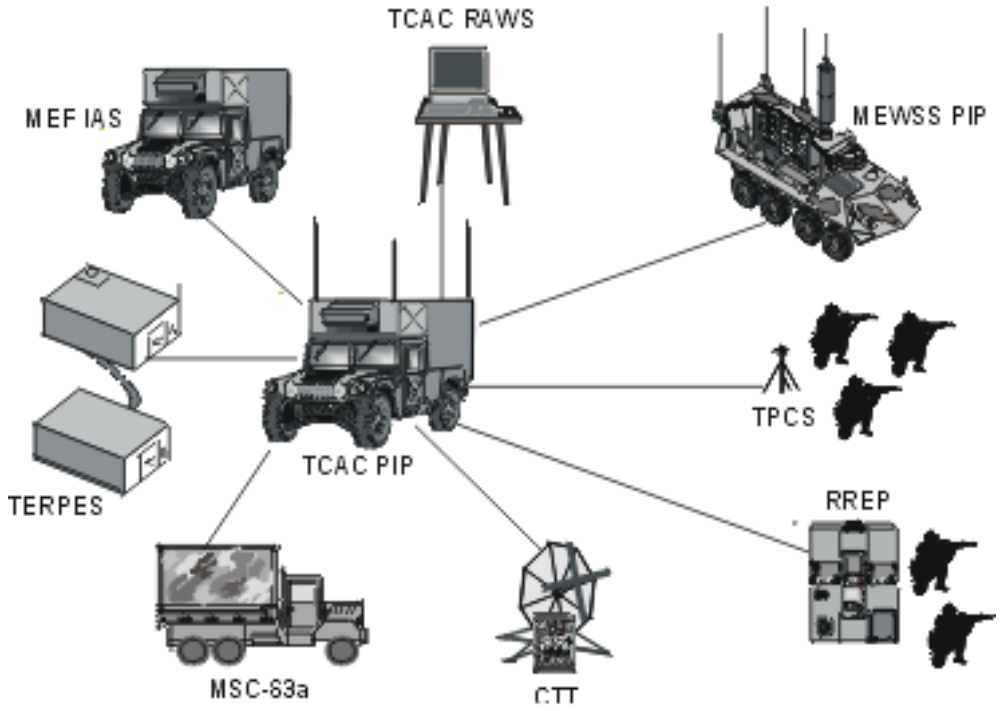

Figure B-7. Technical Control and Analysis Center Concept of Employment.

AN/MYQ-8 TCAC-PIP

The AN/MYQ-8 TCAC-PIP will replace the TCAC. It will consist of three remoteable analysis workstations (RAWSs), one communications interface module (CIM), and one supervisor control module (SCM). Each workstation will consist of modularly designed component equipment fully integrated to perform their intended functions.

Remoteable Analysis Workstation

RAWS provides the capability to perform necessary analysis and reporting functions at a central location or a more forward deployed site, remoted from the TCAC shelter. During shelter operations, a RAWS will be electrically interconnected to the other terminals in the shelter. During remote operations, a RAWS will be connected to the shelter via local area network (LAN) or radio link. It could operate in a stand-alone mode.

Communications Interface Module

CIM provides man-machine interface to communication subroutines that support the interface between the TCAC PIP and other RadBn systems (e.g., team portable collection system, mobile electronic warfare support system) or external intelligence agencies.

Supervisor Control Module

SCM provides a man-machine interface to file server and supervisor subroutines to support system control and overall supervision of the TCAC PIP workstations.

AN/USC-55 Commander's Tactical Terminal

The AN/USC-55 commander's tactical terminal (CTT) is a multiservice-developed, special application, UHF satellite communications receiver that can be dedicated to receive critical, time-sensitive intelligence by commanders and intelligence centers at all echelons, in near-real-time, at GENSER or SCI levels. The receiver provides one full-duplex and two receive-only channels. Planned concept of employment for CTT is similar to that of the tactical receive equipment (TRE) fielded widely within the MAGTF to allow access to intelligence broadcasts and intelligence collectors and producers. Full operational capability for CTT is expected during fiscal year 1999.

Team Portable Collection System Upgrade

The team portable collection system (TPCS) upgrade (figure B-8) is a semiautomated, man-transportable communications intelligence (COMINT) system. It provides intercept, collection, radio direction finding, analysis, reporting, and collection management support. The system provides significant SIGINT capabilities in a modular configuration that can be deployed by component as a stand-alone COMINT system or as part of the integrated RadBn SIGINT and MAGTF intelligence efforts. TPCS uses state-of-the-art equipment that consolidates information and expedites the delivery of critical COMINT to MAGTF and external commanders and agencies. The upgrade will extend the frequency range of the system and provide capabilities against modern signals.

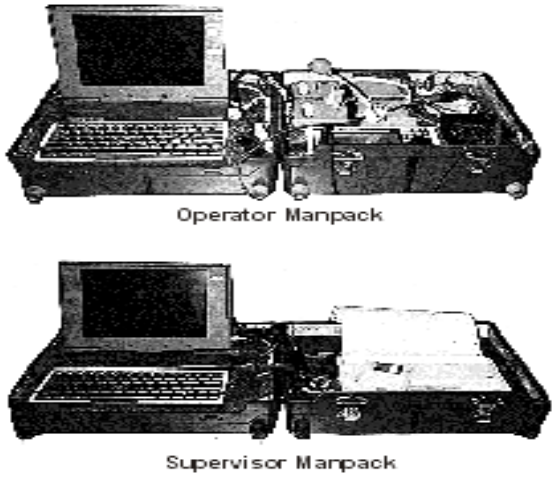

Figure B-8. Team Portable Collection System Upgrade.

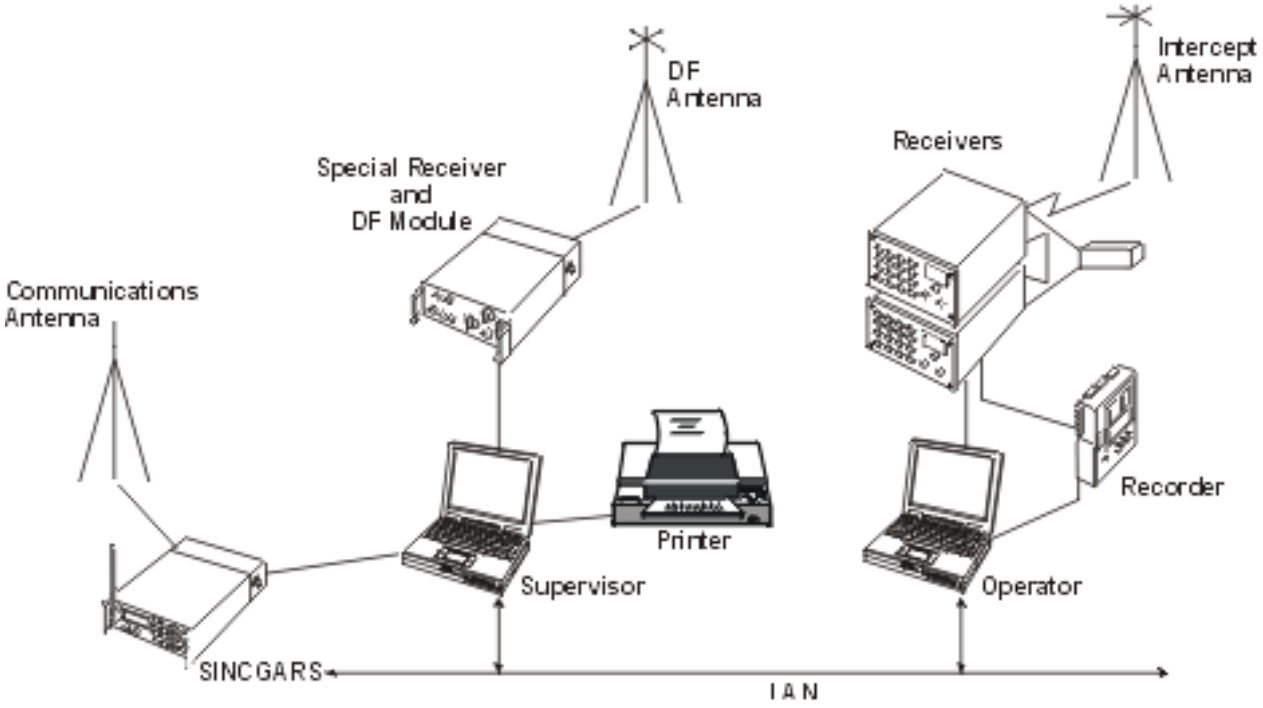

Figure B-9. Team Portable Collection System COMINT Collection Subsystem.

TPCS upgrade is comprised of three subsystems: a COMINT collection subsystem (CCS), including the AN/PRD-12 direction finding set (to be replace by TOPMAKER) and collection receivers (see figure B-9 on the facing page); an analysis subsystem (AS) (figure B-10); and a communications subsystem (CS). Modern single-channel radio nets are used to link TPCS upgrade outstations with the RadBn TCAC to allow automated processing and dissemination of collected information and ultimate dissemination to the MAGTF G-2/S-2 and other organizations. Full operational capability for TPCS upgrade is expected by the second quarter of fiscal year 2001.

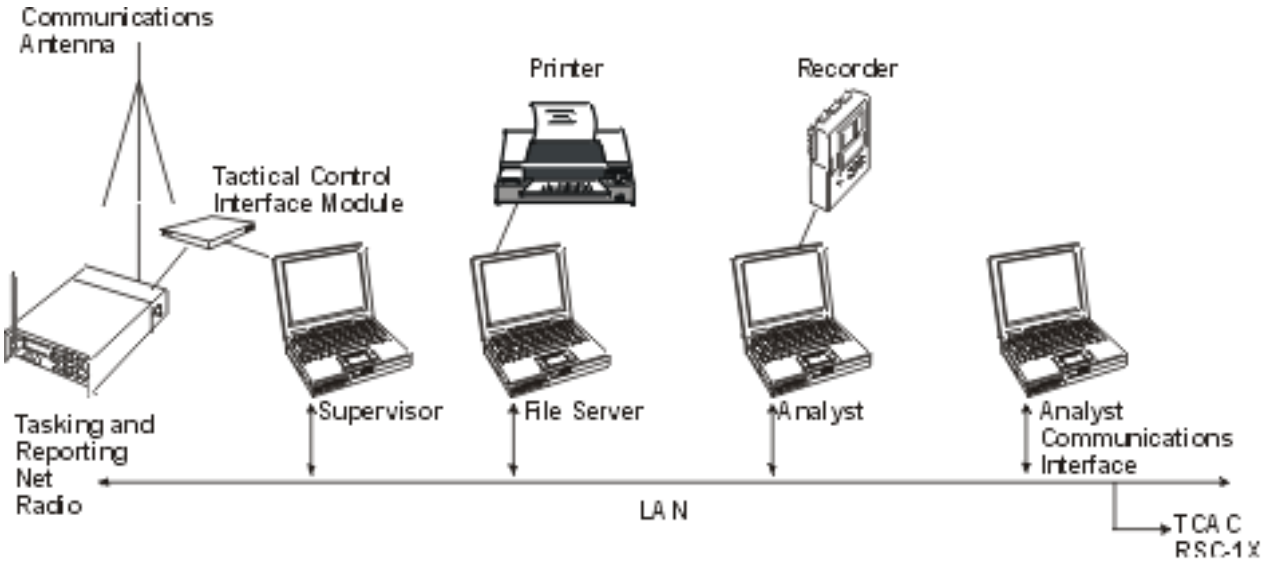

Figure B-10. Team Portable Collection System Analysis Subsystem.

Trojan Spirit II

Trojan Spirit II (TS II) is a mobile SHF satellite communications (SATCOM) system that uses commercial or military satellites to receive, transmit, and process secure, voice, data, video teleconferencing (VTC), and facsimile communications. See figure B-11. TS II provides 14 channels of digital voice or data (SCI or GENSER) with a maximum aggregate data rate of 1.544 megabytes per second (Mbps). LAN communications are supported by SCI and GENSER ethernets. Routers provide access to the secret internet protocol router network, the Joint Worldwide Intelligence Communications System, National Security Agency platform, and the defense SATCOM system. These capabilities provide the necessary dedicated communications for coordinating MAGTF SIGINT and other intelligence operations. The system consists of three HMMWVs with mounted standard integrated command post lightweight multipurpose shelters, tunnel-mounted power generation units, a towed 2.4 meter (C, Ku-band), and a 6.1 meter (C, Ku, X-band) antenna.

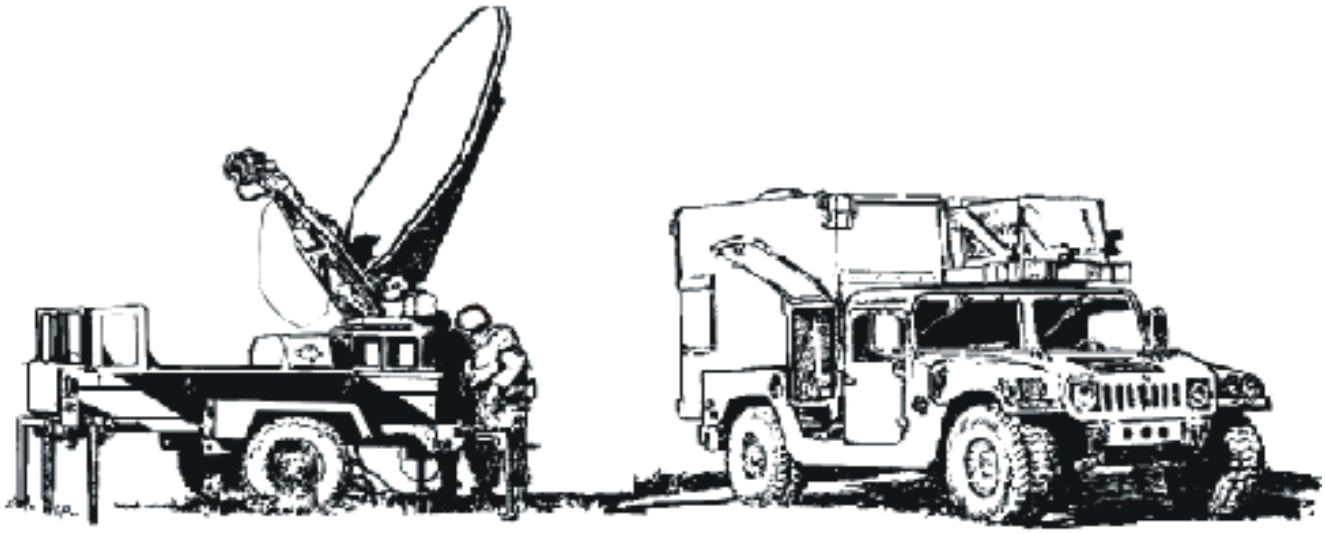

Figure B-11. Trojan Spirit II.

Radio Reconnaissance Equipment Program

The radio reconnaissance equipment program (RREP) SIGINT suite (SS)-1 is a semiautomated, integrated radio intercept and DF system composed of a ruggedized computer and six functional modules that plug together. See figure B-12. RREP SS-1 modules may operate independently or semi-independently through the use of the ruggedized, handheld computer system. It is designed to enable preplanned product improvements and future technology upgrades. The selected equipment will enable the radio reconnaissance teams (RRTs) to target the majority of low-level, single-channel, unencrypted tactical signals of interest used by military, police, insurgents, and other potential hostile forces throughout the world. RREP SS-1 will be employed by RRTs during advance force, preassault and deep postassault conventional, and special operations, under any environmental, climatic, or weather conditions. The system is designed to lighten the individual RRT Marine's combat load as well as to enhance the RRT's operational signal search and technical data base development collection operations.

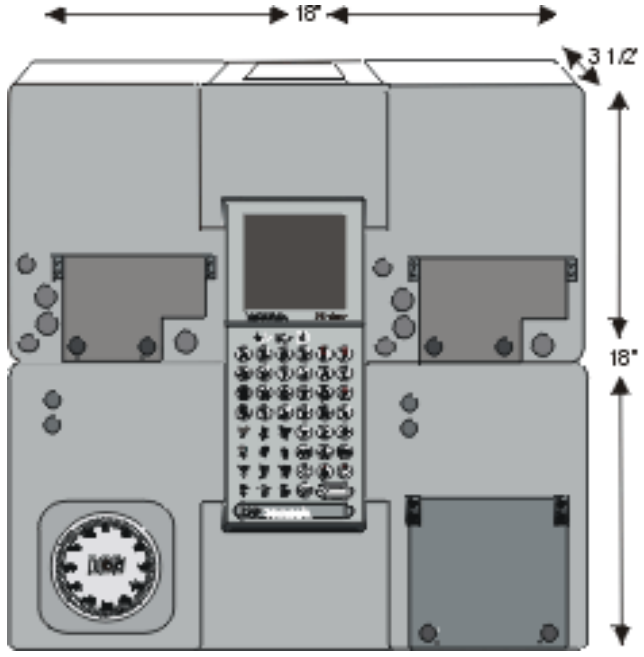

Figure B-12. RREP SS-1.

The RREP SS-2 will provide a highly deployable, man-transportable, signals intercept and DF system employed by RRTs in support of the entire spectrum of MAGTF operations. See figure B-13. RREP SS-2 employs advanced receiver capabilities, cellular phone and other digital communications collection and DF technology, global positioning system map navigation software, a more modular design, and electronic attack capabilities. As with RREP SS-1, the SS-2 operates at the modular level and at the integrated system level. The system can be controlled manually or via subcompact personal computer.

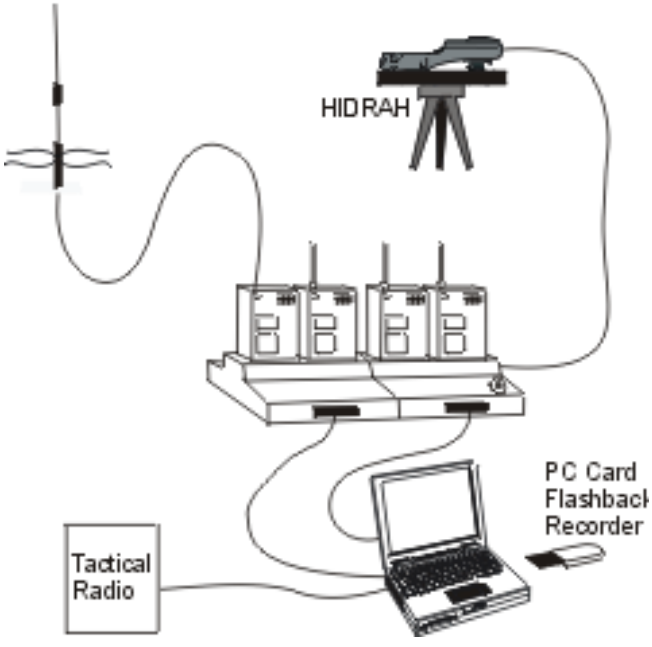

Figure B-13. RREP SS-2.

The handheld integrated directional receiver and homing (HIDRAH) system is a man-transportable, tactical, cordless, radio intercept and signal line-of-bearing (LOB) DF system consisting of several commercial off-the-shelf items of equipment fully integrated in a single, ruggedized and weather-resistant housing. HIDRAH provides RRTs with a threat I&W capability during radio reconnaissance foot-mobile patrols and signal homing support for tactical recovery of aircraft and personnel operations. The HIDRAH system has a unique design that may be employed independently in a handheld manner or by mounting it to an M16 rifle (figure B-14).

Figure B-14. Rifle-Mounted HIDRAH.

Section II. Radio Battalion SIGINT Equipment Technical Characteristics

Designator	Description	Frequency Coverage	Modulation
AN/MLQ-36	MEWSS; COMINT collect/process/ analysis; EA	20-80 MHz (collection and DF expandable to 500 MHz)	AM, FM, ICW, SSB, FSK
AN/MLQ-36A	MEWSS-PIP; COMINT/ELINT collect/process/geolocation; EA	0.5 MHz - 40 GHz	conventional, low probability of intercept
AN/PRD-12	direction finder set, man packable	.5 - 500 MHz	AM, FM, ICW, SSB, FSK
AN/ULQ-19(V)2	electronic attack set; EA	20 - 79.975 MHz	FM
AR-2002	commercial VHF/UHF frequency scanner; COMINT	25 - 550 MHz, 800 - 1300 MHz	AM, FM
AR-2500	commercial HF/VHF/ UHF frequency scanner; COMINT	1 - 1500 MHz	AM, FM, CW, SSB
AR-2515	commercial HF/VHF/ UHF frequency scanner; COMINT	5 - 1500 MHz	AM, FM
AR-3000	commercial HF/VHF/ UHF frequency scanner; COMINT	0.1 - 2036 MHz	AM, FM, CW, SSB
EB-100	receiver, miniport VHF/UHF; DF	20 - 1000 MHz intercept and DF	AM or FM
HEXJAMS	hand-emplaced, expendable jammers	barrage jam 20 - 80 MHz	NA
HIDRAH	COMINT collection, DF	.1 - 1900 MHz intercept 25 - 1000 MHz DF	AM, FM, USB, LSB, CW
IC-R71A	general coverage HF receiver; COMINT	0.1 - 30 MHz	AM, FM, CW
IC-R7000	general coverage VHF/UHF receiver; COMINT	25 - 1300 MHz	AM, FM, SSB
IC-R9000	general coverage HF/VHF/UHF receiver; COMINT	0.1 - 1999.80 MHz	AM, FM, CW, SSB
ICF-PR080	commercial HF/VHF handheld frequency scanner; COMINT	.15 - 108 MHz & 115.15 - 223 MHz	AM, FM, SSB
MPR-88	receiver, miniport VHF/UHF, ruggedized; COMINT	20 - 1000 MHz intercept	AM or FM
R-2174(P)/URR	radio receiver, general purpose, HF; COMINT	0.5 - 29.999 MHz	AM, FM, CW, SSB
RREP SS-1	COMINT collection, DF	1 - 2000 MHz intercept 25 - 1000 MHz DF	AM, FM, USB, LSB, CW
RREP SS-2	COMINT collection, DF	.1 - 1900 MHz intercept 25 - 1000 MHz DF	AM, FM, USB, LSB, CW
WJ-8616	radio receiver, general purpose, HF; COMINT	0.5 - 29.999 MHz	AM, FM, CW, SSB
WJ-8618	radio receiver, general purpose, VHF/UHF; COMINT	20 - 500 MHz	AM, FM, CW, pulse
WJ-8654	radio receiver, general purpose, COMINT	.5 MHz - 1.0 GHz	AM, FM, CW, pulse

Section III. VMAQ SIGINT and EW Equipment

EA-6B Prowler

The EA-6B Prowler (figure B-15) is a subsonic advanced warfare carrier capable aircraft, powered by twin turbojet engines. The crew is composed of one pilot and three electronic countermeasure officers. The AN/ALQ-99 tactical jamming system effectively incorporates receivers and external pods for power and transmission of jamming signals. The Prowler receives and processes designated signals of interest (SOIs) for jamming selected SOIs for subsequent processing and analysis and employs the AGM-88 high-speed antiradiation missile (HARM).

Figure B-15. EA-6B Prowler.

AN/TSQ-90D/E(V) TERPES

The AN/TSQ-90D/E(V) tactical electronic reconnaissance processing and evaluation system (TERPES) receives, processes, evaluates, and displays electronic reconnaissance and EA mission information received from the EA-6B aircraft and other theater and national electronic intelligence (ELINT) assets (figure B-16). TERPES also assists the MAGTF aviation combat element's (ACE) air strike mission planning and intelligence requirements. It is a multisource, integrated, tactical ELINT data processing, correlation, and fusion system installed in a S-280-size transportable shelter. TERPES supports the ELINT and EA/ES mission and VMAQ and MAGTF ACE commander's intelligence requirements. TERPES may be transported by aircraft, shock-mounted air-ride commercial or tactical ground vehicle, or attachable mobilizer for short distances.

Figure B-16. AN/TSQ-90D/E(V), TERPES Portable Unit.

Appendix D

SIGINT Appendix Format

This appendix should explain how SIGINT elements supporting or under the operational control of the MAGTF will be used to support this plan. It should also provide guidance to subordinate commanders for the conduct of SIGINT operations and the support of SIGINT elements and personnel identified to fulfill the SIGINT requirements in this plan.

APPENDIX 2 (Signals Intelligence) to ANNEX B (Intelligence) to Operation Order _____ ( )

Ref: (a) Unit standing operating procedures (SOPs) for intelligence and counterintelligence

(b) Combatant commander, joint task force, or other higher authorities' operation orders (OPORDs) and tactics, techniques, and procedures directives

(c) (List other documents that provide guidance required for SIGINT and supporting operations planning functions.)

1. ( ) <u>SITUATION</u>

a. ( ) <u>Enemy Situation</u>. (Reference Appendix 8 [Intelligence Estimate] to Annex B. Describe the threat and potential threat, the basic situation and the SIGINT operations perspective. Identify the enemy's command and contro tactical and electronic orders of battle; and estimates of the enemy's centers of gravity, critical vulnerabilities, intentions, capabilities, and possible courses of action pertinent to SIGINT operations. When possible, identify finished intelligence products supporting these findings. Reference Annex B and current intelligence estimates for threat capabilities, limitations, vulnerabilities, order o battle, and assessed courses of action.)

CLASSIFICATION

b. ( ) Friendly Situation. (Reference Annex C [Operations] and other pertinent sources.)

c. ( ) SIGINT Support Available. (Reference Annex A [Task Organization], Annex B, and other pertinent sources. Identify organic, attached, and supporting SIGINT elements available to support MAGTF intelligence operations. Specify elements attached to or in direct support of any subordinate unit.)

2. ( ) MISSION

(State concisely the SIGINT mission as it relates to the command's planned operation.)

3. ( ) EXECUTION

a. ( ) Concept of Operations. (Summarize pertinent command relationships, task organization, main and supporting efforts, and the scope of MAGTF and supporting SIGINT and relevant all-source intelligence operations.)

b. ( ) Tasks for SIGINT and Subordinate Units and Task Force Commanders and Officers in Charge (OICs).

(1) ( ) Radio battalion (RadBn) SIGINT support unit (SSU) commanding officer or OIC

(2) ( ) Aviation combat element commander (special attention to VMAQ tasks)

(3) ( ) Ground combat element (GCE) commander

(4) ( ) Rear area operations center (RAOC) commander

(5) ( ) (Others as appropriate)

(This section may include direction, requirements, authority, and other guidance regarding SIGINT elements placed in direct support of MAGTF subordinate element. Also it may include tactical sensitive compartmented [SCI] facilities, special security offices, physical security, and personnel supporting SIGINT and SCI operations, etc.)

CLASSIFICATION

c. ( ) Coordinating Instructions. (Restatement of MAGTF priority intelligence requirements; detailed procedures for intelligence requirements management; SIGINT support requests; direct liaison among subordinate commanders, MAGTF SIGINT units, staff officers, and pertinent external organizations and agencies; routine and time-sensitive reporting and formats; etc.)

4. ( ) ADMINISTRATION AND LOGISTICS

a. ( ) Logistics. (Reference Annex D [Logistics]. Identify unique combat service support requirements, procedures, and guidance to support MAGTF SIGINT units and operations. Specify procedures for specialized technical logistics support necessary from external organizations [e.g., from Director, National Security Agency, or via service cryptologic element channels].)

b. ( ) Personnel. (Reference Annex E [Personnel]. Identify SIGINT-unique personnel requirements and concerns, including global sourcing support and contracted linguist requirements.)

c. ( ) Consolidated Listing and Impact Assessment of Shortfalls and Limiting Factors. (Provide a consolidated listing and impact assessment of personnel and equipment shortfalls and other limiting factors that significantly affect unit SIGINT operations and support. Identify resource problems and specify key tasks that might not be accomplished adequately.)

5. ( ) COMMAND AND CONTROL

(Reference the MAGTF's and SIGINT units' SOPs and Appendix 10 [Intelligence Operations Plan]. Provide guidance as appropriate on the following, including internal unit and external organizations' command and control [C2])

a. ( ) Command Relationships. (Reference Annex J [Command Relationships]. Provide any instructions necessary regarding command relationships arrangements that will influence MAGTF SIGINT operations, with special attention to C2 relationship concerning SIGINT elements attached to or in direct support of MAGTF subordinate units.)

b. ( ) Information Management. (Reference Annex U [Information Management], Annex C [Operations], and Appendix 10 to Annex B. Provide any instructions necessary regarding information management [e.g., time-sensitive and routine SIGINT reporting criteria, SIGINT data bases, administration and access, reports] that will influence MAGTF SIGINT operations.)

CLASSIFICATION

c. ( ) Communications and Information Systems (CIS) . (Reference Appendix 10 to Annex B and Annex K [Communications and Information Systems]. Provide any instructions necessary regarding CIS that will influence MAGTF SIGINT operations.)

d. ( ) SIGINT C2 Nodes and Facilities. (Reference the MAGTF's and SIGINT units' SOPs and Appendix 10 to Annex B. Provide any guidance and instructions necessary regarding the establishment and operations of SIGIN C2 nodes and facilities [e.g., the operations control and analysis center, amphibious task force ship's signals exploitation spaces] and their integration with other MAGTF C2 nodes [e.g., the MAGTF all-source fusion center, the surveillance and reconnaissance center, the reconnaissance operations center, the amphibious task force intelligence center, electronic warfare coordination center].)

TAB A (Communications Intelligence Operations Requirements) to APPENDIX 2 (Signals Intelligence) to ANNEX B (Intelligence) to Operation Order _____( )

1. ( ) GENERAL

(The purpose of this tab is to identify operations requirements for communications intelligence [COMINT] support to the planned MAGTF operation.)

NOTE: SCI controls may require this tab to be published separately from the basic OPORD, Annex B and/or Appendix 2.

a. ( ) (Orient COMINT collection, processing and exploitation, production, and dissemination efforts to answer the questions listed in paragraphs 2 and 3 below.)

b. ( ) (These requirements should address both organic and external direct support SIGINT resources tasked to support the MAGTF.)

c. ( ) (Reference other pertinent portions of Annex B and current intelligence estimates.)

2. ( ) COMINT OPERATIONS REQUIREMENTS AND MANAGEMENT

a. ( ) Classification. (Designate the overall classification of the information included. Assign the lowest classification possible consistent with established security guidelines.)

b. ( ) Statement of Requirement. (Describe in detail COMINT information need, priority, specification of timeliness, location accuracy, and periodicity using the following format:

(1) ( ) Requirement. A detailed narrative statement of the requirement.

CLASSIFICATION

(2) ( ) Priority. The priority of each requirement specification, using the following criteria for assigning priority:

(a) ( ) Priority 1. Intelligence vital to successful plan implementation (forms the basis for the most crucial operational decisions).

(b) ( ) Priority 2. Intelligence of critical importance to plan implementation, required for making operational decisions and planning future operations.

(c) ( ) Priority 3. Intelligence of major importance to plan implementation, including intelligence required for the security of significant numbers of United States (and allied) forces.

(d) ( ) Priority 4. Intelligence of considerable importance to plan implementation (makes important contribution to operational decisionmaking and planning).

(e) ( ) Priority 5. Intelligence of moderate importance to plan implementation (makes moderate contribution to operational decisionmaking and planning).

(f) ( ) Priority 6. Intelligence of some importance to plan implementation (contributes in a measurable way to operational decisionmaking and planning).

(g) ( ) Priority 7. Intelligence of interest to plan implementation.

(3) ( ) Time. (Identify the maximum delay acceptable for receipt of information by the intended user [e.g., within 10 minutes after recognition].)

(4) ( ) Location Accuracy. (Identify the minimum locational accuracy for which the information is needed [e.g., 95-percent confidence, within 1 kilometer of center mass, within 25 kilometers of emitter location].)

(5) ( ) Periodicity. (Identify the maximum amount of time that should pass before the target is covered again [i.e., once every 24 hours or once every 8 hours].)

CLASSIFICATION

c. ( ) User Echelon(s). (Identify the primary echelon needing the information [e.g., GCE, RAOC]. List multiple users only if all data elements o subparagraph 2c above are the same for all listed echelons; otherwise, restate the requirement.)

d. ( ) Geographic Area. (Specify the geographic area for which the requirement specification applies, defined precisely [i.e., Country X, 0 to 50 km from western border; or Country Y, 50 to 75 km from southeastern border].)

e. ( ) Justification. (For each requirement specification, indicate the operational function(s) or purpose(s) [i.e., artillery targeting or air reconnaissance planning].)

3. ( ) UPON IMPLEMENTATION OF THE OPORD. (List, in the manner described above, the COMINT operational requirements that become relevant upon implementation of the plan. Use subsequent paragraphs to reflect additional support requirements for planned phases of combat operations.)

Appendix E

TSCIF Checklist

The following checklist is provided as a guide when activating and deactivating a tactical sensitive compartmented information facility (TSCIF). The security measures identified should be improved upon as the situation permits. Refer to Director of Central Intelligence Directive (DCID) 1/21, *Physical Security Standards for Sensitive Compartmented Information Facilities*, and Department of Defense Directive (DODD) 5105.21-M-1, *Sensitive Compartmented Information (SCI) Security Manual*, *Administrative Security*, for detailed TSCIF operations policy and procedures.

TSCIF Activation

- ❑ **Obtain site location from advance party personnel.**
- ❑ **Submit request to establish TSCIF to cognizant special security officer (SSO).**
- ❑ **Assign vehicle and/or shelter locations to site personnel.**
- ❑ **Move vehicles into site position. Ensure SCI containers remain locked and guarded unt site is accredited.**
- ❑ **Configure site for operation needs and ease of future movement.**
- ❑ **Erect shelters, antennas, and camouflage.**
- ❑ **Establish internal communications (SSO to access control point and emergency reaction force).**
- ❑ **Review and implement guard procedures.**
- ❑ **Emplace barrier material and restriction signs.**
- ❑ **Establish a 24-hour, single-gate access point (shelter with lights). Provide guards with access roster of authorized personnel.**
- ❑ **Determine location of destruction site (burn barrel, etc.).**
- ❑ **Conduct briefings (i.e., operations security, emergency destruction, emergency evacuation, shift schedule, reaction force, perimeter defense, badge system).**
- ❑ **Doublecheck physical security of site.**
- ❑ **Accredit site; declare site secure.**
- ❑ **Inventory SCI documents and materials as they are unpacked.**
- ❑ **Inform G-2/S-2 of commencement of TSCIF operations.**
- ❑ **Begin SCI operations and communications.**
- ❑ **Send TSCIF activation message.**

TSCIF Deactivation

- ❑ **Receive the order to terminate operations.**
- ❑ **Coordinate deactivation time with the G-2/S-2.**
- ❑ **Zeroize communications security (COMSEC) equipment; ensure message queues are emptied.**
- ❑ **Establish guards for SCI materials; inventory and pack SCI into locked containers.**
- ❑ **Debrief all one-time access personnel.**
- ❑ **Ensure all magnetic media is degaussed a minimum of three times each and all tele type, printers, and/or typewriter ribbons are destroyed or secured with SCI material.**
- ❑ **Sweep all SCI work areas for SCI and other classified materials, including telephone directories, newspapers, magazines, notepads, trash bags, etc. Check desk drawers, underneath desks and boxes, equipment containers, bulletin boards, acetate overlays, etc.**

- ❑ **Ensure all SCI is either packed in proper containers for redeployment or destroyed using established procedures.**
- ❑ **Account for all TSCIF badges and access rosters.**
- ❑ **Make a final inspection of the TSCIF and declare it officially deactivated.**
- ❑ **Send TSCIF deactivation message.**
- ❑ **Ensure all personnel are briefed on movement time and location and SCI is properly controlled.**
- ❑ **Upon termination of operations, return to garrison SCIF, reinventory and account fo all SCI material, reset all combination locks, clear all hand receipts, and clean equipment.**
- ❑ **Update standing operating procedure and files with lessons learned during the operation.**

Appendix F

Glossary

Section I

Acronyms and Abbreviations

AAW ..... antiair warfare
ACE ..... aviation combat element
ADCON ..... administrative control
ADP ..... automatic data processing
AFB ..... Air Force base
AFC ..... all-source fusion center
AI ..... area of interest
AIA ..... Air Force Intelligence Agency
AIG ..... addressee indicator group
AM ..... amplitude modulation
AMP ..... amplifier
AO ..... area of operations
AS ..... analysis subsystem
ATARS ..... advanced tactical airborne reconnaissance system
ATF ..... amphibious task force
ATFIC ..... amphibious task force intelligence center
ATO ..... air tasking order
AWACS ..... airborne warning and control system

BDA ..... battle damage assessment
BE ..... basic encyclopedia
Bn Hq ..... battalion headquarters
bps ..... bits per second
BZO ..... battlesight zero

C2 ..... command and control
C2W ..... command and control warfare
C4I ..... command, control, communications, computers, and intelligence
Capt ..... captain
CATF ..... commander, amphibious task force
CCE ..... company command element
CCIR ..... commander's critical information requirements
CCS ..... COMINT collection subsystem
CDOC ..... cryptologic division officers course
Cdr ..... commander
CE ..... command element
CGS ..... common ground station
CHATS ..... counterintelligence/HUMINT analysis tool set
CI ..... counterintelligence
CIC ..... combat intelligence center
CIM ..... communications interface module
CINC ..... commander in chief
CIS ..... communications and information systems
CJTF ..... commander, joint task force
CLF ..... commander, landing force
CLT ..... company liaison team
CMC ..... Commandant of the Marine Corps
CMO ..... collections management officer
CMS ..... COMSEC materials system
CNSG ..... Commander, Naval Security Group
CO ..... commanding officer
COC ..... current operations center
COMINT ..... communications intelligence
comm ..... communications
COMMARFOR ..... commander, Marine Corps forces
COMMARFORLANT ..... Commander, Marine Corps Forces, Atlantic
COMMARFORPAC ..... Commander, Marine Corps Forces, Pacific
COMSEC ..... communications security
CONPLAN ..... contingency plan
Cpl ..... corporal
CPX ..... command post exercise
CRITICOMM ..... critical communications
CS ..... communications subsystem
CSG ..... cryptologic support group
CSP ..... cryptologic support plan
CSS ..... combat service support
CSSA ..... cryptologic shore support activity

CSSD ..... combat service support detachment
CSSE ..... combat service support element
CTT ..... commander's tactical terminal
CW ..... continuous wave

DASC ..... direct air support center
DCI ..... Director of Central Intelligence
DCID ..... Director of Central Intelligence Directive
DCS ..... Defense Courier Service
DF ..... direction finding
DIA ..... Defense Intelligence Agency
DIAM ..... Defense Intelligence Agency manual
DIRNSA ..... Director, National Security Agency
DLI ..... Defense Language Institute
DMS ..... Defense Message System
DOD ..... Department of Defense
DODD ..... Department of Defense directive
DON ..... Department of the Navy
DONCAF ..... Department of the Navy Central Adjudication Facility
DS ..... direct support
DSSCS ..... defense special security communications system

EA ..... electronic attack
EA-6B ..... all weather electronic attack aircraft (Prowler)
ECAC ..... Electromagnetic Compatibility Analysis Center
ECMO ..... electronic countermeasures officer
ECU ..... environmental control unit
e.g. ..... for example
EHF ..... extremely high frequency
ELINT ..... electronics intelligence
EM ..... electromagnetic
EMCON ..... emission control
EOB ..... electronic order of battle
EP ..... electronic protection
EPL ..... ELINT parameters list
ERP ..... effective radiated power
ES ..... electronic warfare support
EW ..... electronic warfare
EWCC ..... electronic warfare coordination center
EWDS ..... electronic warfare data base system
EWIR ..... electronic warfare integrated reprogramming
EWMSNSUM ..... EW mission summary report
EWO ..... electronic warfare officer

FDM ..... frequency division multiplexing
FIE ..... fly-in echelon
FIIU ..... force imagery interpretation unit
FISINT ..... foreign instrumentation signals intelligence
FM ..... frequency modulation
FMF ..... Fleet Marine Force
FMFM ..... Fleet Marine Force manual
FSCC ..... fire support coordination center
FSK ..... frequency shift key
FSSG ..... force service support group

G-1 ..... manpower or personnel staff officer
G-2 ..... intelligence staff officer
G-3 ..... operations staff officer
G-4 ..... logistics staff officer
G-6 ..... communications and information systems officer
GCE ..... ground combat element
GENSER ..... general service
GHz ..... gigahertz
GS ..... general support; general schedule
GSA ..... General Services Administration
GySgt ..... gunnery sergeant

H&S ..... headquarters and service
HARM ..... high-speed antiradiation missile
HF ..... high frequency
HIDRAH ..... handheld integrated directional receiver and homing
HMMWV ..... high mobility, multipurpose wheeled vehicle
HQMC ..... Headquarters, Marine Corps
HUMINT ..... human resources intelligence

I&W ..... indications and warning
IAA ..... Intelligence Analysis Application
IADS ..... integrated air defense system
IAS ..... intelligence analysis system
ICR ..... intelligence collection requirement
ICW ..... interrupted continuous wave
ID ..... identification
IDR ..... intelligence dissemination requirement
i.e. ..... that is
IEWCS ..... intelligence and electronic warfare common sensor
IMINT ..... imagery intelligence

INSCOM..... U.S. Army Intelligence and Security Command
intel .....intelligence
IPR ..... intelligence production requirement
IR .....intelligence requirement
ISSM ..... information system security manager
ISSO..... information system security officer
ITS .....individual training standards
ITT ..... interrogator-translator team

JC2WC..... Joint Command and Control Warfare Center
JCS ..... Joint Chiefs of Staff
JDISS .....joint deployable intelligence support system
JFACC ..... joint force air component commander
JFC ....joint force commander
JFLCC..... joint force land component commander
JFMCC.....joint force maritime component commander
JIC .....joint intelligence center
JISE..... joint intelligence support element
JMCIS ..... joint maritime command information system
JSC.....joint spectrum center
JSIPS ..... Joint Service Imagery Processing System
J-TENS..... Joint Tactical Exploitation of National Systems
JTF .....joint task force
JWICS.....Joint Worldwide Intelligence Communications System

LAN .....local area network
LAV ..... light armored vehicle
LCpl .....lance corporal
LE.....law enforcement
LOB ..... line of bearing
LOS ..... line of sight
LSB ..... lower sideband
Lt.....lieutenant
LTI ..... limited technical inspection

MAG ..... Marine aircraft group
MAGTF ..... Marine air-ground task force
MARDIV ..... Marine division
MARFOR .....Marine Corps forces
MarSptBn ..... Marine support battalion
MASINT .....measurement and signature intelligence
MATCD ..... Marine air traffic control detachment
MAW .....Marine aircraft wing
Mbps ..... megabytes per second
MCB..... Marine Corps base
MCO ..... Marine Corps Order
MCW .....modulated continuous wave
MCWP .....Marine Corps warfighting publication
MECDL ..... mission equipment control data link
MEF .....Marine expeditionary force
MEU .....Marine expeditionary unit
MEU(SOC) .....Marine expeditionary unit (special operations capable)
MEWSS .....mobile electronic warfare support system
MEWSS PIP .....mobile electronic warfare support system product improvement program
MHz .....megahertz
MIDB ..... modernized integrated data base
MISSI..... multilevel information system security initiative
MOS ..... military occupational specialty
MSC.....major subordinate command
MSE .....major subordinate element
MSgt.....master sergeant
MSPF ..... maritime special purpose force
MUX ..... multichannel radio

NATO ..... North Atlantic Treaty Organization
NATOPS..... Naval Air Training and Operating Procedures Standardization
NAVSUP ..... Navy supplement
NCA ..... National Command Authorities
NCO.....noncommissioned officer
NCOIC ..... noncommissioned officer in charge
NCS.....net control station
NCW ..... non-codeword
NDA.....nondisclosure agreement
NEF.....naval expeditionary force
NID .....naval intelligence data base
NIMA ..... National Imagery and Mapping Agency
NIPRNET..... nonsecure internet protocol router network
NIST..... national intelligence support team
NMCC..... National Military Command Center

NRO ..... National Reconnaissance Office
NRT ..... near-real-time
NSA ..... National Security Agency
NSANET ..... National Security Agency Network
NSG ..... Naval Security Group
NSGA ..... Naval Security Group Activity
NSOC ..... National Security Operations Center
NTF ..... naval task force
NTTC ..... Naval Technological Training Center

OAS ..... offensive air support
OBREP ..... order of battle report
OCA ..... operations control and analysis
OCAC ..... operations control and analysis center
OccFld ..... occupational field
OIC ..... officer in charge
OLT ..... OCAC liaison team
ONI ..... Office of Naval Intelligence
OOB ..... order of battle
OPCON ..... operational control
OPLAN ..... operation plan
OPNAV ..... Office of the Chief of Naval Operations
OPORD ..... operation order
OTH ..... over the horizon
OWO ..... operations watch officer

PCM ..... pulse code modulation
PIP ..... product improvement program
PIR ..... priority intelligence requirement
PU ..... participating unit

RadBn ..... radio battalion
RAOC ..... rear area operations center
RAWS ..... remoteable analysis workstation
recon ..... reconnaissance
RF ..... radio frequency
RFI ..... request for intelligence
RREP ..... radio reconnaissance equipment program
RRP ..... radio reconnaissance platoon
RRT ..... radio reconnaissance team
RSOC ..... regional security operations center
RSR ..... resource status report
RU ..... reporting unit

S-1 ..... manpower or personnel staff officer
S-2 ..... intelligence staff officer
S-3 ..... operations staff officer
S-4 ..... logistics staff officer
S-6 ..... communications and information systems staff officer
SALUTE ..... size, activity, location, unit, time, and equipment
SARC ..... surveillance and reconnaissance center
SATCOM ..... satellite communications
SCAMP ..... sensor control and management platoon
SCE ..... service cryptologic element
SCI ..... sensitive compartmented information
SCIF ..... sensitive compartmented information facility
SCM ..... supervisor control module
SCR ..... single-channel radio
Sgt ..... sergeant
SHF ..... super high frequency
SI ..... special intelligence
SIDS ..... secondary imagery dissemination system
SIGINT ..... signals intelligence
SINCGARS ..... single-channel ground and airborne radio system
SIO ..... signals intelligence officer
SIPRNET ..... secret internet protocol router network
SNCO ..... staff noncommissioned officer
SNCOIC ..... staff noncommissioned officer in charge
SOC ..... special operations capable
SOI ..... signal of interest
SOP ..... standing operating procedure
SOTA ..... SIGINT operational tasking authority
SPINTCOMM ..... special intelligence communications
SPMAGTF ..... special-purpose Marine air-ground task force
SS ..... SIGINT suite
SSB ..... single sideband
SSBI ..... single-scope background investigation
SSCC ..... special security communications center
SSCT ..... special security communications team
SSE ..... SIGINT support element
SSES ..... ship's signals exploitation space
SSgt ..... staff sergeant
SSO ..... special security officer
SSOC ..... special security operations center
SST ..... SIGINT support team
SSU ..... SIGINT support unit

STAFFEX ..... staff exercise
STU III..... secure telephone unit-type III

TACC..... tactical air command center (USMC) tactical air control center (USN)
TACELINT..... tactical ELINT
TACINTEL..... tactical intelligence
TACREP ..... tactical report
TACSAT.....tactical satellite
TAD ..... temporary additional duty
TADIL ..... tactical digital information links
TAMPS ..... Tactical Aircraft Mission Planning System
TAOC ..... tactical air operations center
TCAC ..... technical control and analysis center
TCAE..... technical control and analysis element
TCIM .....tactical control interface module
TCO .....tactical combat operations
TDDS.....tactical receive equipment and related applications program data dissemination system
TDN ..... tactical data network
T/E .....table of equipment
TEAMS ..... tactical EA-6B mission planning system
TECHCON.....technical control
TEG.....tactical exploitation group
TENCAP .....tactical exploitation of national capabilities program
TEPP..... TERPES ELINT preprocessor
TERPES.....Tactical Electronic Reconnaissance Processing and Evaluation System
TFP.....TERPES fusion processor
TIBS.....tactical information broadcast system
TJS .....tactical jamming system
T/O ..... table of organization
topo ..... topographic
TPCS .....team portable collection system
TPFDD.....time-phased force and deployment data
TPU.....TERPES portable unit
TRAP.....TRE and Related Applications
TRE .....tactical receive equipment
TRIB ..... tactical remote intelligence broadcast
TRIXS ..... Tactical Reconnaissance Intelligence Exchange System
TRSS.....tactical remote sensor system
TS II..... Trojan Spirit II
TSCIF..... tactical sensitive compartmented information facility
TSCM ..... technical surveillance countermeasures
TSR.....telecommunications service request
TTP..... tactics, techniques, and procedures

UAV.....unmanned aerial vehicle
UHF ..... ultra high frequency
USAF.....United States Air Force
USB ..... upper sideband
USMC..... United States Marine Corps
USSID ..... United States Signals Intelligence Directive
USSS ..... United States SIGINT System

VHF ..... very high frequency
VMAQ .....Marine tactical electronic warfare squadron
VPN .....voice product net
VTC ..... video teleconferencing

WAN..... wide area network

Section II

Definitions

A

all-source intelligence Intelligence products and/or organizations and activities that incorporate all sources of information, including, most frequently, human resources intelligence, imagery intelligence, measurement and signature intelligence, signals intelligence, and open source data, in the production of finished intelligence. (Join Pub 1-02)

amphibious objective area—A geographical area, delineated in the initiating directive, for purposes of command and control (C2) within which is located the objective(s) to be secured by the amphibious task force (ATF). This area must be of sufficient size to ensure accomplishment of the ATF's mission and must provide sufficient area for conducting necessary sea, air, and land operations. Also called AOA. (Joint Pub 1-02)

area of interest—That area of concern to the commander, including the area of influence, areas adjacent thereto, and extending into enemy territory to the objectives of current or planned operations. This area also includes areas occupied by enemy forces who could jeopardize the accomplishment of the mission. Also called AOI. (Joint Pub 1-02)

area of operations—An operational area defined by the joint force commander for land and naval forces. Areas of operation do not typically encompass the entire operational area of the joint force commander, but should be large enough for component commanders to accomplish their missions and protect their forces. Also called AO. (Joint Pub 1-02)

B

basic intelligence—Fundamental intelligence concerning the general situation, resources, capabilities, and vulnerabilities of foreign countries or areas which may be used as reference material in the planning of operations at any level and in evaluating subsequent information relating to the same subject. (Joint Pub 1-02)

battle damage assessment—The timely and accurate estimate of damage resulting from the application of military force, either lethal or nonlethal, against a predetermined objective. Battle damage assessment can be applied to the employment of all types of weapon systems (air, ground, naval, and special forces weapon systems) throughout the range of military operations. Battle damage assessment is primarily an intelligence responsibility with required inputs and coordination from the operators. Battle damage assessment is composed of physical damage assessment, functional damage assessment, and target system assessment. Also called BDA. (Joint Pub 1-02) In Marine Corps usage, the timely and accurate estimate of the damage resulting from the application of military force. BDA estimates physical damage to a particular target, functional damage to that target, and the capability of the entire target system to continue its operations. (MCRP 5-12C)

battlespace—All aspects of air, surface, subsurface, land, space, and electromagnetic spectru which encompass the area of influence and area of interest. (MCRP 5-12C)

battlespace dominance—The degree of control over the dimensions of the battlespace which enhances friendly freedom of action and denies enemy freedom of action. It permits force sustainment and application of power projection to accomplish the full range of potential operational and tactical missions. It includes all actions conducted against enemy capabilities to influence future operations. (MCRP 5-12C)

C

centralized control—In military operations, a mode of battlespace management in which one echelon of command exercises total authority and

direction of all aspects of one or more warfighting functions. It is a method of control where detailed orders are issued and total unity of action is the overriding consideration. (MCRP 5-12C)

collection—In Marine Corps usage, the gathering of intelligence data and information to satisfy the identified requirements. (MCRP 5-12C)

collection management—The process of converting intelligence requirements into collection requirements, establishing priorities, tasking o coordinating with appropriate collection sources or agencies, monitoring results and retasking, as required. (Joint Pub 1-02) Its purpose is to conduct an effective effort to collect all necessary data while ensuring the efficient use of limited and valuable collection assets. (MCRP 2-1)

combat data—Data derived from reporting by operational units. (MCRP 5-12C)

combatant command—A unified or specified command with a broad continuing mission under a single commander established and so designated by the President through the Secretary of Defense and with the advice and assistance of Chairman of the Joint Chiefs of Staff. Combatant command typically have geographic or functional responsibilities. (Joint Pub 1-02)

command and control—The exercise of authority and direction by a properly designated commander over assigned and attached forces in the accomplishment of the mission. Command and control functions are performed through an arrangement of personnel, equipment, communications, facilities, and procedures employed by a commander in planning, directing, coordinating, and controlling forces and operations in the accomplishment of the mission. Also called C2. (Joint Pub 1-02) The means by which a commander recognizes what needs to be done and sees to it that appropriate actions are taken. (MCRP 5-12C)

command and control warfare—The integrated use of operations security, military deception, psychological operations, electronic warfare, and physical destruction, mutually supported by intelligence, to deny information to, influence, degrade, or destroy adversary command and control capabilities, while protecting friendly command and control capabilities against such actions. Also called C2W. (Joint Pub 2-0)

commander's critical information requirements—Information regarding the enemy and friendly activities and the environment identified by the commander as critical to maintaining situational awareness, planning future activities, and facilitating timely decisionmaking. Also called CCIR. Note: CCIRs are normally divided into three primary subcategories: priority intelligence requirements, friendly force information requirements, and essential elements of friendly information. (MCRP 5-12C)

commander's intent—A commander's clear, concise articulation of the purpose(s) behind one or more tasks assigned to a subordinate. It is one of two parts of every mission statement which guides the exercise of initiative in the absence of instructions. (MCRP 5-12C)

communications intelligence—Technical and intelligence information derived from foreign communications by other than the intended recipients. Also called COMINT. (Joint Pub 1-02)

communications security—The protection resulting from all measures designed to deny unauthorized persons information of value which might be derived from the possession and study of telecommunications, or to mislead unauthorized persons in their interpretation of the results o such possession and study. Also called COMSEC. (Joint Pub 1-02 extract)

coordination—The action necessary to ensure adequately integrated relationships between separate organizations located in the same area. Coordination may include such matters as fire support, emergency defense measures, area intelligence and other situations in which coordination is considered necessary. (MCRP 5-12C)

critical information—Specific facts about friendly intentions, capabilities, and activities vitally needed by adversaries for them to plan and

act effectively so as to guarantee failure or unacceptable consequences for friendly mission accomplishment. (Joint Pub 1-02)

critical intelligence—Intelligence which is crucial and requires the immediate attention of the commander. It is required to enable the commander to make decisions that will provide a timely and appropriate response to actions by the potential/ actual enemy. It includes but is not limited to the following: a. strong indications of the imminent outbreak of hostilities of any type (warning of attack); b. aggression of any nature against a friendly country; c. indications or use of nuclear-biological-chemical weapons (target); and d. significant events within potential enemy countries that may lead to modification of nuclear strike plans. (Joint Pub 1-02)

critical vulnerability—An aspect of a center of gravity that if exploited will do the most significant damage to an adversary's ability to resist. A vulnerability cannot be critical unless it undermines a key strength. Also called CV. (MCRP 5-12C)

D

decentralized control—In military operations, a mode of battlespace management in which a command echelon may delegate some or all authority and direction for warfighting functions to subordinates. It requires careful and clear articulation of mission, intent, and main effort to unify efforts of subordinate leaders. (MCRP 5-12C)

descriptive intelligence Class of intelligence which describes existing and previously existing conditions with the intent to promote situational awareness. Descriptive intelligence has two components: *basic intelligen* , which is general background knowledge about established and relatively constant conditions; and *current intelligence*, which is concerned with describing the existing situation. (MCRP 5-12C)

detachment—1. A part of a unit separated from its main organization for duty elsewhere. 2. A temporary military or naval unit formed from other units or parts of units. (Joint Pub 1-02)

direction finding—A procedure for obtaining bearings of radio frequency emitters by using a highly directional antenna and a display unit on an intercept receive or ancillary equipment. (Joint Pub 1-02)

dissemination—Conveyance of intelligence to users in a suitable form. (Joint Pub 1-02)

E

electronic attack—That division of electronic warfare involving the use of electromagnetic, directed energy, or antiradiation weapons to attack personnel, facilities, or equipment with the intent of degrading, neutralizing, or destroying enemy combat capability. Also called EA. (Joint Pub 1-02)

electronic protection—That division of electronic warfare involving actions taken to protect personnel, facilities, and equipment from any effects of friendly or enemy employment of electronic warfare that degrade, neutralize, or destroy friendly combat capability. Also called EP. (Joint Pub 1-02)

electronic reconnaissance—The detection, identification, evaluation, and location of foreign electromagnetic radiations emanating from other than nuclear detonations or radioactive sources. (Joint Pub 1-02)

electronic warfare—Any military action involving the use of electromagnetic and directed energy to control the electromagnetic spectrum or to attack the enemy. Also called EW. The three major subdivisions within electronic warfare are electronic attack, electronic protection, and electronic warfare support. (Joint Pub 1-02)

electronic warfare support—That division of electronic warfare involving actions tasked by, or under direct control of, an operational commander to search for, intercept, identify, and locate sources of intentional and unintentional radiated electromagnetic energy for the purpose of immediate threat recognition. Thus, electronic warfare support provides information required for immediate decisions involving electronic warfare operations

and other tactical actions such as threat avoidance, targeting, and homing. Also called ES. Electronic warfare support data can be used to produce signals intelligence (SIGINT), both communications intelligence (COMINT), and electronic intelligence (ELINT). (Joint Pub 1-02)

electronic intelligence—Technical and geolocation intelligence derived from foreign noncommunications electromagnetic radiations emanating from other than nuclear detonations or radioactive sources. Also called ELINT. (Joint Pub 1-02)

essential elements of friendly information—Key questions likely to be asked by adversary officials and intelligence systems about specific friendly intentions, capabilities, and activities, so they can obtain answers critical to their operational effectiveness. Also called EEFI. (Joint Pub 1-02) Specific facts about friendly intentions, capabilities, and activities needed by adversaries to plan and execute effective operations against our forces. (MCRP 5-12C)

estimative intelligence Class of intelligence which attempts to anticipate future possibilitie and probabilities based on an analysis of descriptive intelligence in the context of planned friendly and assessed enemy operations. (MCRP 5-12C)

F

friendly force information requirements—Information the commander needs about friendly forces in order to develop plans and make effective decisions. Depending upon the circumstances, information on unit location, composition readiness, personnel status, and logistics statu could become a friendly force information requirement. Also called FFIR. (MCRP 5-12C)

fusion—In intelligence usage, the process of examining all sources of intelligence and information to derive a complete assessment of activity. (Joint Pub 1-02)

G

global sourcing—A process of force provision or augmentation whereby resources may be drawn from any location/command worldwide. (MCRP 5-12C)

I

indications and warning—Those intelligenc activities intended to detect and report time-sensitive intelligence information on foreign developments that could involve a threat to the Unite States or allied military, political, or economic interests or to US citizens abroad. It includes forewarning of enemy actions or intentions; the imminence of hostilities; insurgency; nuclear/non-nuclear attack on the United States, its overseas forces, or allied nations; hostile reactions to United States reconnaissance activities; terrorists' attacks; and other similar events. Also called I&W. (Joint Pub 2-01)

intelligence—The product resulting from the collection, processing, integration, analysis, evaluation, and interpretation of evaluated information concerning foreign countries or areas. Information and knowledge about an adversary obtained through observation, investigation, analysis, o understanding. (Joint Pub 1-02) Also in Marine Corps usage, intelligence is knowledge about the enemy or the surrounding environment needed to support decisionmaking. This knowledge is the result of the collection, processing, exploitation, evaluation, integration, analysis, and interpretation of available information about the battlespace and threat. (MCRP 5-12C)

intelligence cycle—The process by which information is converted into intelligence and made available to users. (Joint Pub 2-01)

intelligence data—Data derived from assets primarily dedicated to intelligence collection such as imagery systems, electronic intercept equipment, human intelligence sources, etc. (MCRP 5-12C)

intelligence discipline—A well-defined area o intelligence collection, processing, exploitation and reporting using a specific category of technical or human resources. There are five major disciplines: human intelligence, imagery intelligence, measurement and signature intelligence, signals intelligence (communications intelligence, electronic intelligence, and foreign instrumentation signals intelligence), and open source intelligence. (Joint Pub 1-02)

intelligence operations—The variety of intelligence tasks that are carried out by various intelligence organizations and activities. (Joint Pub 1-02 extract)

intelligence preparation of the battlespace—An analytical methodology employed to reduce uncertainties concerning the enemy, environment, and terrain for all types of operations. Intelligence preparation of the battlespace builds an extensive data base for each potential area in which a unit may be required to operate. The data base is then analyzed in detail to determine the impact of the enemy, environment, and terrain on operation and presents it in graphic form. Intelligence preparation of the battlespace is a continuing process. Also called IPB. (Joint Pub 1-02) In Marine Corps usage, the systematic, continuous process of analyzing the threat and environment in a specific geographic area. (MCRP 5-12C)

intelligence requirement—1. Any subject, general or specific, upon which there is a need for the collection of information or the production of intelligence. (Joint Pub 1-02 2. In Marine Corps usage, questions about the enemy and the environment, the answers to which a commander requires to make sound decisions. Also called IR. (MCRP 5-12C)

J

joint deployable intelligence support system—A transportable workstation and communications suite that electronically extends a joint intelligence center to a joint task force or other tactical user. Also called JDISS. (Joint Pub 1-02)

joint force—A general term applied to a force composed of significant elements, assigned or attached, of two or more Military Departments, operating under a single joint force commander. (Joint Pub 1-02)

joint intelligence center—The intelligence center of the joint force headquarters. The joint intelligence center is responsible for providing and producing the intelligence required to support the joint force commander and staff, components, task forces and elements, and the national intelligence community. Also called JIC. (Joint Pub 1-02)

Joint Worldwide Intelligence Communications System—The sensitive compartmented information portion of the Defense Information System Network. It incorporates advanced networking technologies that permit point-to-poin or multipoint information exchange involving voice, text, graphics, data, and video teleconferencing. Also called JWICS. (Joint Pub 1-02)

M

main effort—The designated subordinate unit whose mission at a given point in time is mos critical to overall mission success. It is usually weighted with the preponderance of combat power and is directed against a center of gravity through a critical vulnerability. (MCRP 5-12C)

maneuver warfare—A warfighting philosophy that seeks to shatter the enemy's cohesion through a variety of rapid, focused, and unexpected actions which create a turbulent and rapidly deteriorating situation with which the enemy cannot cope. (MCRP 5-12C)

Marine Corps Planning Process—A six-step methodology which helps organize the though processes of the commander and staff throughout the planning and execution of military operations. It focuses on the threat and is based on the Marine Corps philosophy of maneuver warfare. It capitalizes on the principle of unity of command and supports the establishment and maintenance o tempo. The six steps consist of mission analysis, course of action development, course of action analysis, comparison/decision, orders development, and transition. Also called MCPP. Note: Tenets of the MCPP include top down planning, single battle concept, and integrated planning (MCRP 5-12C)

N

named area of interest—A point or area along a particular avenue of approach through which enemy activity is expected to occur. Activity or lack of activity within a named area of interest will

help to confirm or deny a particular enemy course of action. Also called NAI. (MCRP 5-12C)

national intelligence support team—A nationally sourced team composed of intelligence and communications experts from either Defense Intelligence Agency, Central Intelligence Agency, National Security Agency, or any combination of these agencies. Also called NIST. (Joint Pub 2-01)

O

operational architecture—A description (often graphical) of the operational elements, assigned tasks, and information flows required to support the warfighter. It defines the type of information, the frequency of exchange, and what tasks are supported by these information exchanges. Also called OA. (MCRP 5-12C)

operational control—Transferable command authority that may be exercised by commanders a any echelon at or below the level of combatan command. Operational control is inherent in combatant command (command authority). Operational control may be delegated and is the authority to perform those functions of command over subordinate forces involving organizing and employing commands and forces, assigning tasks, designating objectives, and giving authoritative direction necessary to accomplish the mission. Operational control includes authoritative direction over all aspects of military operations and joint training necessary to accomplish mission assigned to the command. Operational control should be exercised through the commanders o subordinate organizations. Normally this authority is exercised through subordinate joint force commanders and Service and/or functional component commanders. Operational control normally provides full authority to organize commands and forces and to employ those forces as the commander in operational control considers necessary to accomplish assigned missions. Operational control does not, in and of itself, include authoritative direction for logistics or matters of administration, discipline, internal organization, or un training. Also called OPCON. (Joint Pub 1-02)

operations control and analysis center—Main node for the command and control of radio battalion signals intelligence operations and the overall coordination of MAGTF signals intelligence operations. Processes, analyzes, produces, and disseminates signals intelligence-derived information and directs the ground-based electronic warfare activities of the radio battalion. Also called OCAC. (MCRP 5-12C)

order of battle—The identification, strength, command structure, and disposition of the personnel, units, and equipment of any military force Also called OOB. (Joint Pub 1-02)

P

priority intelligence requirements—1. Those intelligence requirements for which a commander has an anticipated and stated priority in his task of planning and decisionmaking. Also called PIR. (Joint Pub 1-02) 2. In Marine Corps usage, an intelligence requirement associated with a decision that will critically affect the overall success of the command's mission. (MCRP 5-12C)

production management—Encompasses determining the scope, content, and format of each intelligence product, developing a plan and schedule for the development of each product, assigning priorities among the various production requirements, allocating processing, exploitation, and production resources, and integrating production efforts with intelligence collection and dissemination. (MCRP 5-12C)

R

reach back—The ability to exploit resources, capabilities, expertise, etc., not physically located in the theater or a joint operations area, when established. (MCRP 5-12C)

S

sensitive compartmented information All information and materials bearing special community controls indicating restricted handling within present and future community intelligence collection programs and their end products for which

community systems of compartmentation have been or will be formally established. (These controls are over and above the provisions of DOD 52001R, Information Security Program Regulation.) Also called SCI. (Joint Pub 1-02)

sensitive compartmented information facility—An accredited area, room, group of rooms, or installation where sensitive compartmented information may be stored, used, discussed, and/or electronically processed. SCIF procedural and physical measures prevent the free access of persons unless they have been formally indoctrinated for the particular SCI authorized for use or storage within the SCIF. Also called SCIF. See also sensitive compartmented information. (Joint Pub 1-02)

sensor data—Data derived from sensors whose primary mission is surveillance or target acquisition, such as air surveillance radars, counterbattery radars, and remote ground sensors. (MCR 5-12C)

Service component command—A command consisting of the Service component commander and all those Service forces such as individuals units, detachments, organizations, and installations under the command, including the support forces that have been assigned to a combatant command, or further assigned to a subordinate unified command or joint task force. (Joint Pub 1-02)

signals intelligence—A category of intelligence comprising either individually or in combination all communications intelligence, electronic intelligence, and foreign instrumentation signals intelligence, however transmitted. Also called SIGINT. (Joint Pub 1-02)

SIGINT operational tasking authority—A military commanders's authority, delegated by DIRNSA/CHCSS, to operationally direct and levy SIGINT requirements on designated SIGINT resources. This includes authority to deploy and redeploy all or part of the SIGINT resources for which SOTA has been delegated. Also called SOTA. (USSID 1, *SIGINT Operating Policy*)

situational awareness—Knowledge and understanding of the current situation which promotes timely, relevant and accurate assessment of friendly, enemy, and other operations within the battlespace in order to facilitate decisionmaking. An informational perspective and skill that foster an ability to determine quickly the context and relevance of events that are unfolding. (MCRP 5-12C)

split base—Two or more portions of the same force conducting or supporting operations fro separate physical locations. (MCRP 5-12C)

surveillance and reconnaissance center—Primary element responsible for the supervision o MAGTF intelligence collection operations. Directs, coordinates, and monitors intelligence collection operations conducted by organic, attached, and direct support collection assets. Also called SARC. (MCRP 5-12C)

sustained operations ashore—The employment of Marine Corps forces on land for an extended duration. It can occur with or without sustainment from the sea. Also called SOA. (MCRP 5-12C)

systems architecture—Defines the physical connection, location, and identification of key nodes, circuits, networks, warfighting platforms, etc and specific system and component performance parameters. The systems architecture is constructed to satisfy operational architecture requirements per standards defined in the technical architecture. The systems architecture shows how multiple systems within a subject area link and interoperate and may describe the internal construction or operations of particular systems within the architecture. Also called SA. (MCRP 5-12C)

T

tactical intelligence—Intelligence that is required for planning and conducting tactical operations. (Joint Pub 1-02) In Marine Corps usage, tactical intelligence is concerned primarily with the location, capabilities, and possible intentions of enemy units on the battlefield and with the tactical aspects of terrain and weather within the battlespace. (MCRP 5-12C)

technical architecture—The technical architecture identifies the services, interfaces, standards, and their relationships. It provides the technica guidelines for implementation of systems upon which engineering specifications are based, common building blocks are built, and product line are developed. Also called TA. (MCRP 5-12C)

technical control—The performance of specialized or professional service, or the exercise o professional guidance or direction through the establishment of policies and procedures.

tempo—The relative speed and rhythm of military operations over time. (MCRP 5-12C)

W

warfighting functions—The six mutually supporting military activities integrated in the conduct of all military operations are:

1. command and control—The means by which a commander recognizes what needs to be done and sees to it that appropriate actions are taken.
2. maneuver—The movement of forces for the purpose of gaining an advantage over the enemy.
3. fires—Those means used to delay, disrupt, degrade, or destroy enemy capabilities, forces, or facilities as well as affect the enemy's will to fight.
4. intelligence—Knowledge about the enemy or the surrounding environment needed to support decisionmaking.
5. logistics—All activities required to move and sustain military forces.
6. force protection—Actions or efforts used to safeguard own centers of gravity while protecting, concealing, reducing, or eliminating friendly critical vulnerabilities.
Also called WF. (MCRP 5-12C)

CHAPTER 1

INTRODUCTION

Section I. GENERAL

1. Purpose

The purpose of this manual is to present a standard approach to traffic analysis problems of the military type in order to furnish signal intelligence personnel with a knowledge of traffic analysis techniques, capabilities, and applications. It is to be recognized that no text on analytic techniques can be definitive because techniques are subject to continual improvement and change in order to meet changing problems. This text is intended merely as a guide. Specific application is dependent on the ability and ingenuity of the analyst.

2. Scope

This manual is concerned only with traffic analysis of military radio communications, but the techniques covered will also be found of value in the analysis of other kinds of communication networks. Discussion of other means of communication, such as wire or cable, has not been included; in the reconstruction of the radio communication system it should be remembered that often these other means will account for missing portions of the system. Further, the scope is limited to the study of Morse transmissions. Non-Morse transmissions, such as radio-teletype and radio-telephone, are not discussed. The differences, however, are largely technical and procedural and involve the material transmitted only to a limited extent. It is thought, therefore, that this text will serve as a basis for all traffic analysis and that, with some minor modification, the methodology described will be found applicable to all types of transmission.

REF ID:A58489

3. References

A general knowledge of radio theory, Morse code, and radio procedure is assumed. For reference purposes the field and technical manuals listed in the appendix will be found useful.

4. Definition of Traffic Analysis

Traffic analysis is that branch of signal intelligence analysis which deals with the study of the external characteristics of signal communications and related materials for the purpose of obtaining information concerning the organization and operation of a communication system. This information is used (1) as a guide to efficient intercept operation, (2) as an aid to cryptanalysis, and (3) as a basis for drawing deductions and inferences of value as intelligence even in the absence of specific knowledge of the contents of the message.

5. Objectives

To achieve planned and coordinated action, it is necessary for the components of a military force to communicate with each other from the highest headquarters through all intermediary channels to the individual man in the field or the airplane in the air. Much of this communication, for reason of speed and efficiency, is conducted by radio, and radio is vulnerable to intercept. Therefore, disguises are devised to conceal both the traffic passed and the structure of the communication network. Traffic is disguised through the employment of codes and ciphers, and it is the task of cryptanalysis to solve these codes and ciphers. The communications net work is disguised through the use of a number of techniques which relate, for example, to the use of call signs and frequencies, the method of routing messages, and the use of secret procedure signs. These techniques, the means for attacking them, and the resulting reconstruction of the network are the study of traffic analysis. The responsibility of the traffic analyst, however, does not stop with the reconstruction of the communication network. It is also part of his mission to discover practical applications for his knowledge in the associated fields of intercept, cryptanalysis, intelligence, and security. The objectives of traffic analysis, then, fall into two main groups:

a. The acquisition of a detailed knowledge and a complete understanding of a communications network. This involves the reconstruction of the nets, the determination of the features of their operation, the solution of call sign and routing systems, analysis of the components of the message externals, the interpretation of radio procedure, and the use of the various cryptographic systems passed; in

REF ID:A58489

other words, everything about communications except the actual cryptanalysis of the text.

b. The application of this knowledge to—

(1) *Intercept operations.* Traffic analysis contributes to three aspects of the intercept problem. First, by providing the intercept station with certain necessary information, such as call sign and frequency lists, target locations, schedules, etc., it assists the station in the accomplishment of its mission and encourages the best possible results. Second, in coordination with cryptanalytic and intelligence interests, it determines the priorities governing the interception of individual circuits. Third, through a study of intercept, it checks the performance of the station in relation to its mission.

(2) *Cryptanalysis.* Aid to cryptanalysis is furnished in a great variety of ways, largely dependent on the cryptanalytic and traffic analytic peculiarities of the communications under study. *In most instances, traffic analysis and cryptanalysis become so interrelated that it is impossible to determine where one begins and the other leaves off, and it is necessary to set an arbitrary dividing line.* In general, however, assistance takes the following forms: the solution of the routing systems, where disguised, and the placing of the routings in the clear on traffic; the study of the uses of the various cryptographic systems; the reading of chatter for items of cryptanalytic interest; the discovery of crib, or stereotype, texts from message externals; the location of isolog messages; and the application of other traffic analysis data, such as message serial numbers, which may be of value in specific cryptanalytic problems.

(3) *Intelligence.* Military communications, including both the organization of the nets and the traffic passed, reflect the disposition of troops and the intentions for movements and operations. A careful analysis, therefore, of net structure, traffic contacts and patterns, traffic volumes, and similar signals features, assists in the building of the final intelligence picture. The exact techniques to be used are, again, dependent on the individual problem and involve the recruitment, training, organization, and order of battle of the military forces under study as well as characteristics of communications.

(4) *Security.* Because the traffic analyst becomes skilled in probing the weaknesses of communication systems, he is in an ideal position to assist in maintaining high standards of security within our own communication networks. This function of traffic analysis is mentioned merely in passing. It will not be discussed further in this text.

REF ID:A58489

Section II. GENERAL APPROACH

6. The Raw Material

The traffic analyst begins his study of a communications network with three types of raw (basic) data:

a. INTERCEPT DATA. This is the information supplied by the intercept operator. It consists of the frequencies to which he is listening, the times during which he hears signals, and occasional comments such as notes on the quality of the signal or the characteristics of the radio operator.

b. THE TRANSMISSION. The transmission is the sum total of everything sent by the radio operators. It includes the initial call-up, the exchange of call signs, the traffic, servicing, miscellaneous chatter, and signing off. Traffic may be divided into two parts: the message externals (preamble and postamble) and the text. The externals generally contain radio station and message center numbers of a variety of types, routing instructions, addresses, precedence indicators, and file times, all of value in traffic analysis. The text usually exhibits a number of cryptographic features in the clear which are likewise of use.

c. COLLATERAL INFORMATION. Besides the above material, there is a large amount of data which is available or which can be made available for traffic analysis purposes. Some of these are directly related to intercept, such as goniometric bearings. Other items are message decodes, captured documents, and intelligence reports.

7. The Analytic Approach

a. Traffic analysis is partly analytic, partly synthetic. Analysis is performed on each feature of the communications network and then, through exploiting the relationships between these features or within them, traffic analysis synthesizes them into a unified whole. In other words, the types of raw data noted in paragraph 6 are first analyzed until everything possible is known about each item independently, after which, though often seemingly unrelated, they can be pieced together to produce a complete picture of the radio nets. This means that the analyst must pay particular attention to detail and must carry much of this detail in his mind so that he can readily perceive the relationships between discrete items and integrate them to form the whole.

b. The actual approach to a traffic analysis problem is broadly determined by the stage of development of the problem. These stages of development are threefold, but it should be understood that what is represented are not clear-cut divisions in operation, but rather, gradual shiftings of emphasis as the problem matures.

REF ID:A58489

(1) *Initial attack.* (*a*) In the initial period, little is known about the problem and it may first be necessary to identify the radio nets and traffic involved so that they can be distinguished from all other types. When this has been accomplished, the characteristics are furnished to the intercept station which embarks on a large-scale search mission, scanning the entire range of frequencies for transmissions of the desired nature. During this time, it is the task of the traffic analyst to give direction to this mission and to evolve from it a definite assignment. It should be noted here that the search mission, in reduced scale, should always continue until the problem has ceased to exist, in order to cover new net developments.

(*b*) As soon as material begins to accumulate, an elementary study may be conducted on the elements of the transmission, particularly the message externals. The functions of the various preamble components should be observed, the method of routing noted, and in general, the significance of each component determined.

(2) *Development.* During the second period, emphasis is placed on the study of the communications system with a view to learning all its details of organization, operation, and procedure. There are usually two phases to this: the research phase, which involves thorough analysis of every item, such as call signs, procedure signs, message numbers, routing codes, and cryptographic features; and the actual net reconstruction, consisting of the building of the entire radio net complete with call signs, frequencies, schedules, and station locations.

(3) *Application.* When this knowledge has been gained, and even while it is being gained, it can be put to use in the three related fields of control, cryptanalysis, and intelligence. From the very first moment that traffic analysis is performed, it begins contributing to these phases of communications intelligence, but it is not until a substantial amount of information has been gathered that these applications receive full emphasis. The final goal of traffic analysis operations is the reconstruction of the complete radio network against its cryptographic and order of battle background, and the production on a day-to-day basis of items of cryptanalytic application and intelligence importance.

REF ID:A58489

CHAPTER 2

RADIO OPERATIONS

Section I. INTRODUCTION

8. Radio Operations

a. The operation of a radio network requires a set of fixed rules and regulations which define the manner and form of communications. These rules are in part subject to the laws of nature, in part to the necessities of communication itself, and in part to the whim and ingenuity of the personnel formulating them. The first two factors impose some degree of uniformity on radio networks, no matter what the type or nationality. This makes it possible to set down the basic features of communications, e.g., call signs, frequencies, message numbers, and routing instructions. However, the third factor acts to vary those features by determining the way that they are used. This chapter outlines what these basic features are and some of the ways in which they may be manipulated. It is, of course, not possible to include all the types which may be encountered, but it is hoped that what is given will serve to indicate the general patterns the traffic analyst is likely to meet in studying radio operations and will serve to set up general lines of traffic analysis thinking.

9. Phases of Radio Operations

Radio operations for purposes of study may be divided into four main phases:

a. Operating Data. The first considerations in the creation of a communication net relate to the structure or form of the net, the use of frequencies and call signs, and the system of schedules. These are the basic operating data of the net and involve its mechanical functioning. In the case of some nets, the military for instance, attempts are made to conceal these data; in other cases, such as commercial, they can be determined with little effort.

b. The Radio Transmission. Once the operating data have been determined, the next step is to devise the form and language of radio transmission. There must be regulations governing the Morse code to be used (largely dependent on the alphabet concerned), the pro-

REF ID:A58489

cedure signals which make for brevity and speed and which may be encoded for reasons of security, the order of elements in the transmission, the plain-language chatter of the radio operators, and the plain-language and simple cipher messages usually considered part of the traffic analysis task.

c. THE MESSAGE EXTERNALS. The message externals are actually a part of the radio transmission and belong under *b* above, but because of their importance a separate section (sec. IV, this ch.) is devoted to them. They include the preamble and postamble and generally contain serial numbers of various types, group check, file date and time, precedence indicators, and routing instructions.

d. TEXTUAL FEATURES. Some of the cryptographic aspects of the text are in the clear to make possible proper handling of the traffic by message center personnel and to permit decrypting. These features in the clear are often of great assistance to the traffic analyst. They may merely involve whether the text is in letters or numbers, or the length of the code groups, or they may be somewhat more complex as discriminants, indicators, or pad numbers.

Section II. OPERATING DATA

10. General

The operating data enable the network to function. They consist of the frequencies, call signs, and schedules used in communication. Traffic analysis is interested not only in the operating data as used by the network, but also in the general system on which the allocation of operating data to specific nets and radio stations is based. This section is devoted to a discussion of radio nets and of the ways in which the operating data are used and assigned.

11. Definitions

a. A radio network is composed of radio stations organized for the purpose of intercommunication. This organization is not haphazard but follows very definite and detailed patterns. These patterns are based on the order of battle since the lines of communication themselves must coincide with the echelon of command and the military requirements. Before it is possible to enter into a discussion of these patterns, however, it is necessary to define some of the terminology to be used.

(1) *Link:* Any system of telecommunication between two points.

(2) *Group:* One or more links whose stations work together as a communication entity under a common operating control.

REF ID:A58489

(3) *Net:* One group or a number of groups assembled on the basis of common operating characteristics, presumably under the administrative direction of an immediate common superior headquarters.

(4) *Network:* The radio system of a service of a nationality, as United States Army network, United States Naval network, United States Air Force network.

b. These definitions may appear somewhat obscure to the student for the moment, but it should be kept in mind that they are formulated from a traffic analysis point of view, that is, from the outside looking in. These terms must be so categorized in order to be of value analytically and, therefore, they represent the situation as it appears rather than as it actually is. Figure 1 will help to clarify these terms, and it is suggested that the student study the diagram from time to time as its understanding is essential to the proper approach to net reconstruction.

c. Figure 1 illustrates the general organization of the military network, proceeding from Department of the Army Headquarters through theater, army group, army, corps, and division. The equivalent Department of the Air Force organizations are shown in figure 2. (The following pertains equally to the Department of the Air Force.) Each line or connection represents a radio link within the terms of the definition in *a*(1) above—any telecommunication system between two points. It is to be emphasized that only *two* stations are involved in a link, never any more. Thus, the line from Department of the Army HQ to Theater "A" is a link; the line from Department of the Army HQ to Theater "B" is another; the line from 2d Corps to 1st Division is one; as is the connection from 1st Division to 2d Division. The links which form the triangle, 2d Corps, 1st Division, 2d Division, constitute a group; those forming the triangle, 2d Corps, 3d Division, 4th Division, constitute another. These links are placed in groups because they work together as a communication entity under a common operating control (the group control being at the highest headquarters of the group, here the 2d corps), yet do not, in themselves, comprise the complete net. The net is made up of the two groups together and is, in this instance, the 2d Corps net with the 2d Corps headquarters as net control. It should be observed that very often the link and the group may be the same thing, or the link, group, and net may be the same. Each definition of the larger unit enfolds the lesser. For example, the line from Department of the Army HQ to Theater "A" may be termed a link, for it is composed of only two stations, or a group because its stations work as a communication entity under the control of the Department of the Army station; the three links, or groups, however, running out from Department of the Army HQ form the Department of the Army net.

REF ID:A58489

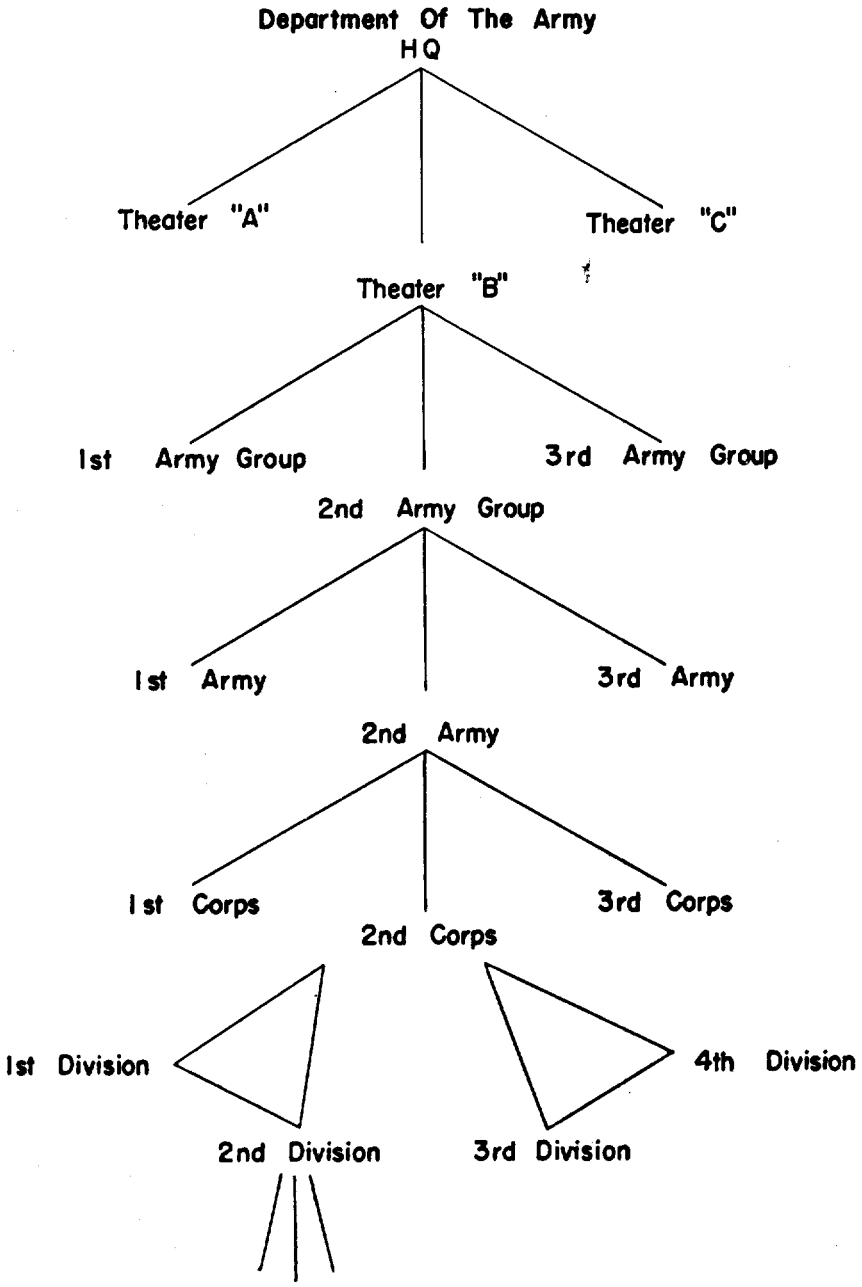

Figure 1. General organization of military network—United States Army.

REF ID:A58489

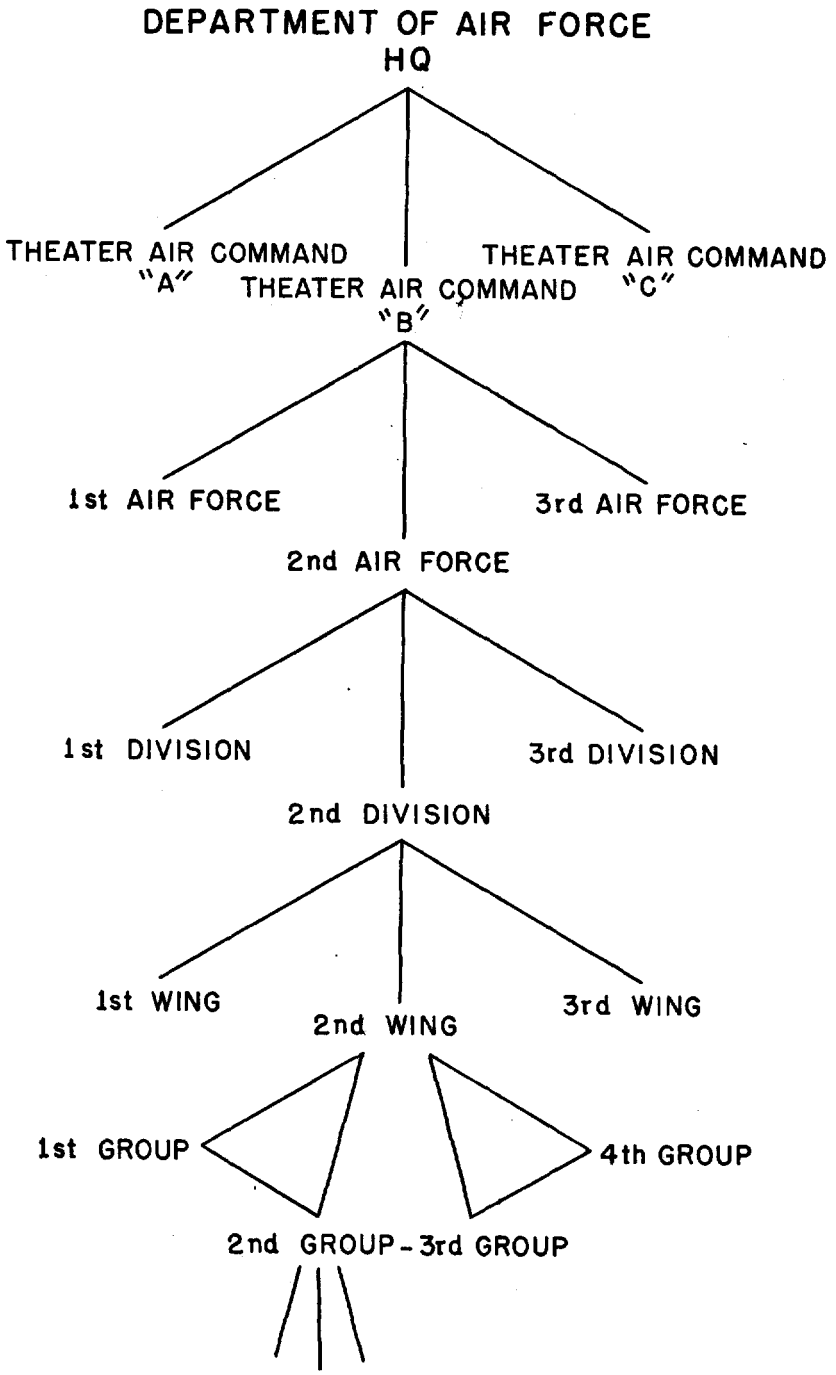

Figure 2. General organization of military network—United States Air Force.

REF ID:A58489

d. It will be recalled that, in discussing these definitions in *b* above, it was stated that they were formulated from an analytic point of view. This is particularly true of the definition of the net. In the reconstruction of the radio network, one of the first problems is the organizing of a number of radio links into groups and nets. In the case of the group, this is fairly simple to accomplish for the group is a communication entity, that is, all of its stations either work each other or have contact with a central operating control. The net, on the other hand, often does not exhibit such cohesive characteristics. A number of groups, apparently unrelated, may eventually fall into a single net when the order of battle is finally derived. There are two touchstones for the association of groups into nets:

(1) *Common operating characteristics.* Since the links and groups of the net all have a common superior headquarters, it may be assumed that certain rules of procedure and operation will be promulgated by this superior and that, therefore, all links and groups of the net will exhibit these in common.

(2) *Administrative direction of an immediate superior headquarters.* When the order of battle is known, it is often possible to associate groups and links through the knowledge that they are controlled by the same unit.

e. The net, the group, and the link, then, are merely units of organization in the radio network, just as armies are broken down into corps, divisions, regiments, companies, and platoons. Likewise, air forces are broken down into divisions, wings, groups, squadrons, and flights. And these nets, groups, and links may be characterized by the unit served and the function performed. For instance, figure 1 represents command channels so that there is a Department of the Army command net, a Theater "B" command net, a 2d Army Group command net, and so on. Radio, however, serves many other military functions than that of command. Military nets, for example, may be organized to contain an antiaircraft artillery group, an artillery air-ground group, an artillery observation group, a reconnaissance group, an air warning group, and others beside the command group.

12. Examples of Radio Nets

Figures 3 through 9 illustrate some of the type nets which may be encountered. These types will vary in individual instances; they serve, however, to indicate some of the possibilities.

13. Frequencies

a. GENERAL. The analysis of the use of frequencies on a network may be divided into two parts:

(1) *Systems of use.* The system of use is concerned with the manner in which frequencies are employed on the net, i.e., whether the entire net uses one frequency, whether each station sends on an individual frequency, etc.

(2) *Systems of allocation.* The system of allocation is the method used to assign specific frequencies for communications so that different stations will not interfere with each other. It also involves the rotation of frequencies for security purposes.

b. SYSTEMS OF USE. (1) *Simplex:* Two stations intercommunicating on the same frequency.

(*a*) A sends to B on 5,000 Kcs.

(*b*) B sends to A on 5,000 Kcs.

(2) *Complex sending* (fig. 10): Two or more stations on different sending frequencies. A different frequency is assigned to each radio transmitter in the net, and each transmitter uses its assigned frequency to contact the other stations.

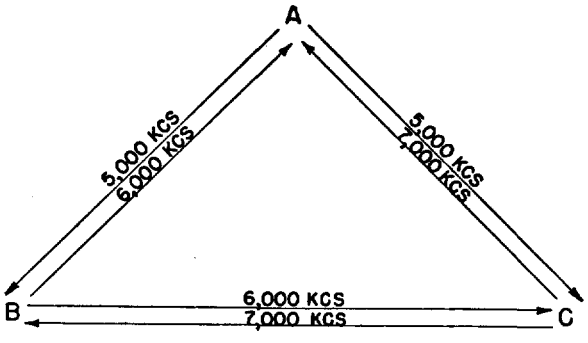

Figure 10.

(*a*) A sends to B and C on 5,000 Kcs.

(*b*) B sends to A and C on 6,000 Kcs.

(*c*) C sends to A and B on 7,000 Kcs.

(3) *Complex receiving* (fig. 11): Two or more stations on different receiving frequencies. A frequency is assigned to each station for receiving transmissions. All stations in the net when sending to a particular station will use the frequency assigned to the receiving station.

REF ID:A58489

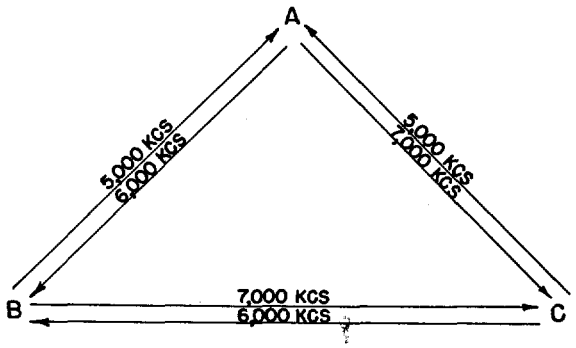

Figure 11.

(*a*) B and C send to A on 5,000 Kcs.

(*b*) A and C send to B on 6,000 Kcs.

(*c*) A and B send to C on 7,000 Kcs.

(4) *Star* (fig. 12): A number of stations on the same frequency with no normal lateral working. This is an extension of the simplex system, as the latter involves only two stations on the same frequency. In the star form, if one outstation wishes to contact another, it must obtain permission from control.

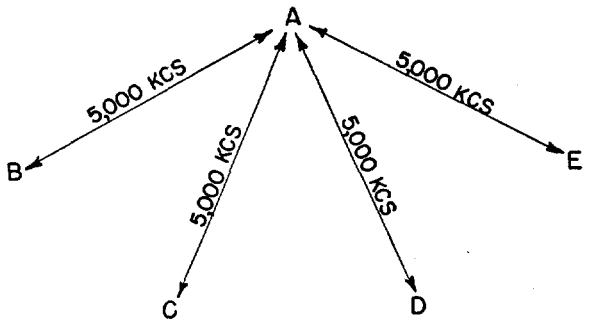

Figure 12.

(*a*) A sends to B, C, D, and E on 5,000 Kcs.

(*b*) B, C, D, and E send to A on 5,000 Kcs. B, C, D, and E may not intercommunicate without express authorization from A. Normally, messages between outstations will be relayed through A (control).

(5) *Star with lateral* (fig. 13): Number of stations on the same frequency with some lateral working. In many of the star nets, lateral working will be a regular procedure between some, but not all, of the outstations.

REF ID:A58489

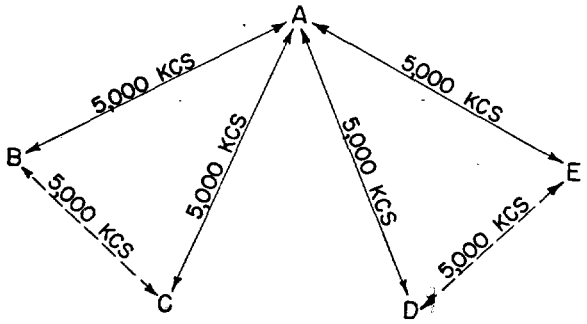

Figure 13.

(*a*) A sends to B, C, D, and E on 5,000 Kcs.
(*b*) B, C, D, and E send to A on 5,000 Kcs.
(*c*) B sends to C on 5,000 Kcs. and C to B on 5,000 Kcs.
(*d*) D sends to E on 5,000 Kcs. and E to D on 5,000 Kcs.

(6) *Free star* (fig. 14): Number of stations on the same frequency with free operation. One frequency is assigned to the entire net and any station in the net may contact any other on the assigned frequency.

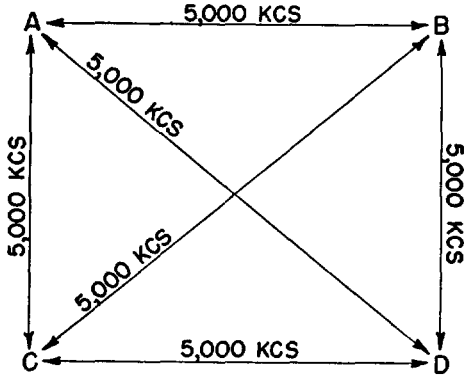

Figure 14.

(*a*) A sends to B, C, and D on 5,000 Kcs.
(*b*) B sends to A, C, and D on 5,000 Kcs.
(*c*) C sends to A, B, and D on 5,000 Kcs.
(*d*) D sends to A, B, and C on 5,000 Kcs.

(7) *Complex star* (fig. 15): Number of stations with control on one frequency, outstations on others. This is similar to the star in its form, but it uses several frequencies instead of only one. Often, a number of the outstations will operate on one frequency, others on another.

REF ID:A58489

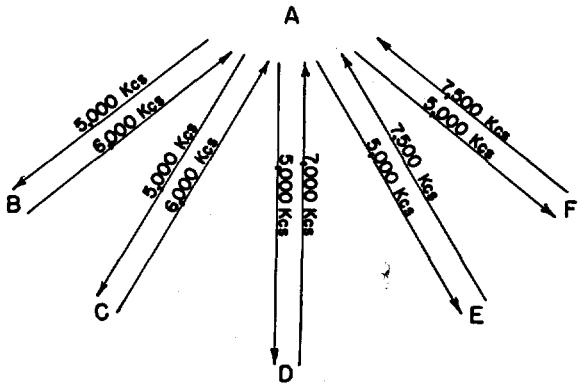

Figure 15.

(*a*) A sends to B, C, D, E, and F on 5,000 Kcs.
(*b*) B and C send to A on 6,000 Kcs.
(*c*) D sends to A on 7,000 Kcs.
(*d*) E and F send to A on 7,500 Kcs.

(8) *Broadcast* (fig. 16): A frequency is assigned to the broadcasting station. Usually no frequency is assigned to the outstations for reply.

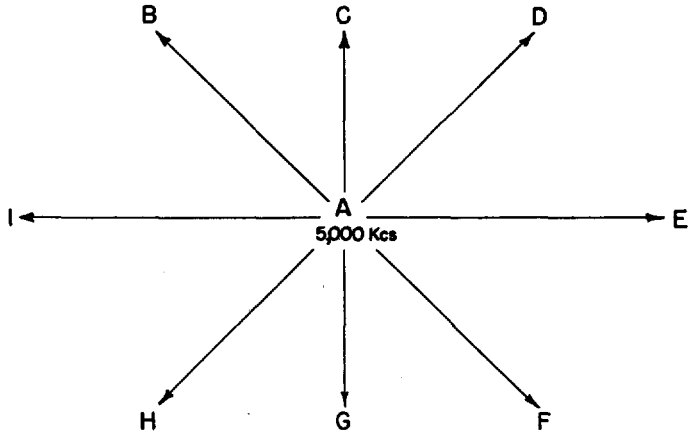

Figure 16.

(*a*) A sends to all stations simultaneously on 5,000 Kcs.

(*b*) Because a broadcast must be heard at so many scattered places, care must be taken in the selection of a frequency in order to choose one that will be heard by all stations. Sometimes, where this has not proved possible, double-keying is resorted to, i.e., the broadcasting station sends on two or more different frequencies at the

REF ID:A58489

same time. Outstations may receipt for traffic on regularly assigned frequencies in the net. In many such nets, however, no receipt is given.

c. SYSTEMS OF ALLOCATION. (1) *General.* Several factors enter into the selection of specific frequencies for use. These involve two basic considerations: readability (the ability of the receiving station to hear) and security. A number of miscellaneous factors, such as the type of power supply available, the nature of the transmitting and receiving equipment, and military and operational requirements, also affect the choice.

(2) *Readability.* The readability of a frequency is dependent on certain factors of wave propagation. These factors involve consideration of the distances between stations, ionospheric conditions, including night and day effects which usually make it necessary to allocate several frequencies to each radio station or net for night and day use, seasonal changes, and the type of terrain, e.g., water, high mountains, and jungle. Furthermore, the possibility of interference between transmitters on approximately the same frequency in the same area must be borne in mind and care taken to avoid such conflict. In any allotment of frequencies, therefore, central control must be established and an over-all plan of allocation devised.

(3) *Security.* One of the methods of attaining security against communications analysis is to hinder the act of intercept. This may be accomplished by changing frequency so that the intercept operator will be forced to "search" the entire frequency range for the desired transmissions. A second effect achieved by these changes is to increase the difficulty of identifying stations or units with frequencies. Maximum effectiveness is obtained by changing call signs along with the frequency. Plans for changes of frequency may operate in a patterned or random fashion, but in any event, such plans must take into consideration the factors noted under (2) above; thus these plans are usually rather detailed and complex.

(4) *Range of frequencies.* Frequencies may range from very low to ultra-high. The latter are not usable for long distance operation and find their chief applications in low echelon, air-ground, and plane to plane communication. Many of the applications of ultra-high frequency transmissions are still in the experimental stage. Low frequencies, such as 300 or 400 kilocycles, may be used for close field contact or air-ground and plane to plane nets. However, the major portion of military transmissions presently falls between 1,500 and 20,000 kcs. In passing, mention should also be made of the use of frequency modulation. FM has found its main application in tank, air, and small combat units where distances are not great and a minimum of noise level is desired for reception.

(5) *Secret frequencies.* As a countermeasure to possible jamming

RET ID: A584489

operations, some nets are provided with secret reserve frequencies These frequencies are not employed except in the case of jamming of the usual frequencies and circumstances demand that communication be kept open The secret frequency, of course, only remains secret for as long as it takes intercept to scan the bands and pick it up, but this interval may be sufficient to complete the transmission

(6) *Example of allocation of frequencies* The following chart illustrates a system which might be used for the allocation and rotation of frequencies

	Jan	*Feb*	*Mar*	*Apr*	*May*	*Jun*	*Jul*	*Aug*		*Dec*
A	1955	2035	2150	1910						
	2035	2150	1910	2305						
	2150	1910	2305	2070						
B	1910	2305	2070	2190						
	2305	2070	2190	2210						
	2070	2190	2210	1940						
C	2190	2210	1940	2350						
	2210	1940	2350	1925						
	1940	2350	1925	2240						
D	2350	1925	2240	1955						
	1925	2240	1955	2035						
	2240	1955	2035							

The months are listed across the top of the chart The squares are divided into three portions representing ten day periods within each month, 1–10, 11–20, 21–31 Each station of the net is assigned a letter and finds its frequency for each period in the square opposite the letter The frequencies which have been selected on the basis of their operational characteristics can be inscribed in the squares at random, in this instance, they are moved up one each month For example, on 1–10 January, A uses 1955 kilocycles, B, 1910 kilocycles, C, 2190 kilocycles On 11–20 January, A uses 2035 kilocycles, B, 2305 kilocycles, C, 2210 kilocycles

14. Call Signs

a General Call signs are actually names for the correspondents in a radio net They are usually composed of letters, numbers, or combinations of both and serve as a convenient means of identification The analysis of call signs falls into the same categories as does the study of frequencies systems of use, and systems of allocation

b Systems of Use (1) *Single station call* One call only is nor-

REF ID:A58489

mally used by the calling station This call may be either the sending station's or the receiving station's call

1 (ABC) _____ 2 (DEF)

Call up	1 to 2	DEF DEF DEF
	2 to 1	DEF DEF DEF
	or	
	1 to 2	DEF DEF DEF
	2 to 1	ABC ABC ABC

Note in this last instance that only one call was used by the calling station This makes the procedure single call even though the reply used a second call

(2) *Double-station call* Both the sending station s and the receiving station's calls are normally used by the calling station

1 (ABC) _____ 2 (DEF)

Call-up	1 to 2	DEF DEF DEF de ABC ABC ABC
	2 to 1	ABC ABC ABC de DEF DEF DEF

(3) *Link call* (fig 17) A common call sign is used for intercommunications between two stations Unlike the previous two types, here the call sign does not belong to an individual station but to a link

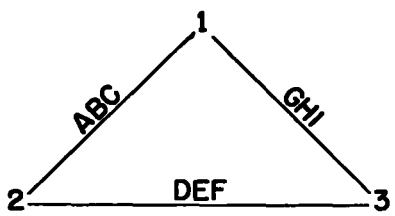

Figure 17

Call up	1 to 2	ABC ABC ABC
	2 to 1	ABC ABC ABC
	1 to 3	GHI GHI GHI
	3 to 1	GHI GHI GHI

(4) *Collective call* In addition to one of the above assignments, a collective call may also be allocated This call is used to alert all stations in the net preparatory to the transmission of broadcast traffic There are also some nets which are maintained only for broadcast purposes and this type of call is usually assigned to such groups The use of "CQ" may be classified under this heading

(5) *Split call working* Usually a single call is assigned to a transmitter or receiver position or to a link However, the use of separate calls for each frequency, one for day, one for night, is also valid This variation may be applied to any of the systems enumer-

REF ID: A684682

ated above and is known as split call working. It has the advantage of dissociating the night and day frequencies, but requires the use of twice as many calls.

(6) *Secondary calls.* In some systems of communication a secondary call is employed in conjunction with link call procedure. These secondary calls are of the station call type and serve as a more definite identification of each station than is supplied by the link call.

(7) *Authenticators.* In order to prevent outside stations from entering a net and confusing its operations, authenticators are sometimes used. They generally consist of a word or a combination of letters and/or digits to which there is a secret, prearranged reply.

c. SYSTEMS OF ALLOCATION. (1) *Composition.* Call signs may be composed of any combination of letters and/or numbers. Usually they are kept as brief as possible and the general range is from 2 to 5 characters. Calls may be composed at random or in some methodical fashion, such as the use of sliding alphabets. An example is included in *d* (2) below.

(2) *Methods of assignment.* Since calls are used as identifying marks, it is necessary to assign them so that two stations operating in proximity or in the same net do not have the same call. Otherwise, confusion would result on call-ups and the passage of traffic hindered. This necessitates some form of over-all control of call sign allocation. This control may be of a very tight nature in which every call is allotted from headquarters down to the smallest unit, or it may be rather loose with considerable discretion left to major subordinate groups whose commands are sufficiently separated geographically to prevent the possibility of confusion. A second consideration in the assignment of calls involves the problem of security since calls are identifications and thereby, if unchanged, furnish continuities for intercept and analysis. Most systems, therefore, cover not only the allotment of calls, but also provisions for change or rotation. These changes may be made daily, weekly, monthly, or at any other interval thought desirable. Calls which change frequently are called "changing calls", those which remain constant for some length of time, are called "fixed".

d. In general, call-sign systems may be divided into two basic groups:

(1) *Book systems.* These systems are founded on a call-sign book from which all calls are taken. These books will usually contain thousands of call signs and some method is provided for the allocation of calls from the book to individual radio stations. The recovery of these books often requires traffic intercept for a period of a year or more.

(2) *Cipher systems.* Call signs may be generated by the use of simple cipher devices such as sliding alphabets and square tables.

REF ID:A58489

The number of call signs available through such systems is usually limited and the method of assigning the call signs to individual radio stations is often bound up with the method for generating the calls. Figure 18 illustrates the use of a cipher system for the allocation and rotation of calls.

1	B	M	A	K	D
2	R	W	C	T	I
3	Z	G	N	O	U
4	H	L	S	X	E
5	V	J	P	F	Y

Figure 18.

The square is filled in random fashion. Station 1 begins with the letter "B" and takes off its calls in diagonal fashion, moving over one diagonal each day. At the end of each line, it drops down one line. Station 2 begins with "R", 3 with "Z", etc. Every 25 days, the calls repeat.

	Station No. ( )				
Date	1	2	3	4	5

15. Times of Communication

a. GENERAL. An integral part of the operating data of the net is the setting of the times for communication. There are two main systems for accomplishing this: Unrestricted signaling and restricted signaling.

b. UNRESTRICTED SIGNALING. Under the system of unrestricted signaling, the stations of a net are free to contact each other at any time they choose. This method may be implemented either by the stations setting the time for the next schedule at the close of the

REF ID:A58489

previous one or by "alert" operating. In alert operating, which finds its greatest use in tactical and warning nets, all stations are always tuned to receive on certain assigned frequencies.

c. RESTRICTED SIGNALING. Restricted signaling limits the time at which contacts may be made between two radio stations. It is divided into two types: period signaling and priority signaling.

(1) *Period signaling.* The times of communication are assigned by definite schedule and contacts are made only at those specific times.

(2) *Priority signaling.* Priority signaling sets down a definite order in which the stations of a net will send traffic. It differs from unrestricted signaling in that one station may not call another at any time; and from period signaling in that no particular time is set aside for one station to call another. An example of priority signaling is shown in figure 19.

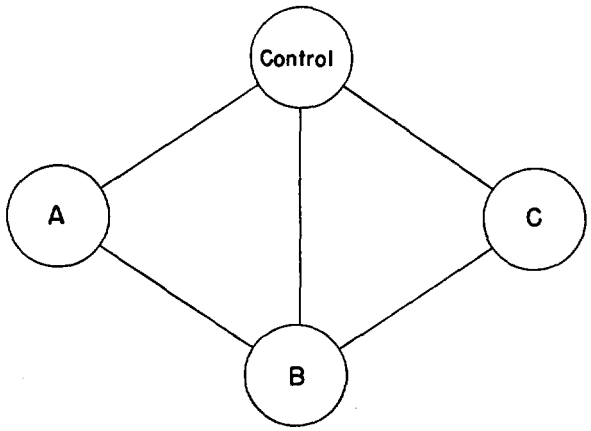

Figure 19.

In this net, "control" is permitted to send first, then stations A, B, and C in order. Schedules may be set up for the hours at which "control" comes on the air.

Section III. ELEMENTS OF RADIO PROCEDURE

16. Morse Code

Morse code is a system of dots and dashes used to transmit letters and numbers by electrical means. In the case of the English alphabet the Morse code is standardized by international convention, is used the world over, and is known as International Morse. In the instance of some nations whose alphabets differ from the English, however, special combinations of dots and dashes have been devised. For

REF ID:A58489

example, in German Morse, the German letters which correspond to the English follow the International, but the umlauted letters and "ch", for which there are no equivalents, are designated by new combinations:

A .—.—
O ———.
U ..——
CH ————

Morse code may be transmitted automatically or manually. In lower-echelon communications, the latter is usually employed, in the higher echelons sending is often automatic. Automatic transmission permits of speeds as high as 400 or 500 words per minute, though generally it averages somewhere between 75 and 200. Manual sending of coded traffic rarely rises above 35 words per minute. Atmospheric conditions, operator abilities, equipment, and similar items are, of course, limiting factors.

17. Procedure Signals

a. In order to facilitate conversation between radio operators, certain signals and signs have been composed. The most common sets of such signals used internationally, are made up of three-letter combinations beginning with "Q" or "Z", and are called "Q Signals" and "Z Signals". The use of these signals saves considerable time and simplifies transmission. Examples are—

QSV Send V's.
QRN I am troubled by atmospherics.
QSA? What is my signal strength?
QSA 4 Your signal strength is 4.

b. Beside these signals, there are a number of standard signs called prosigns which are likewise considered part of international procedure. Some of these are—

AA all after
R received
K go ahead

c. Another type of standard signal is the International Service Code. These signals are made up of five letters in pronounceable form:

UPBAG—for your information

d. Since much information may be derived from a study of chatter, military nets often make up sets of secret procedure signals and, in some cases, may encipher these signals on a periodic basis. For instance, the standard Q signal list may be used, but the last two letters of the signal enciphered by means of a daily changing alphabet.

899152 O - 50 - 5

REF ID:A58489

18. Elements of the Transmission

a. GENERAL. Just as a definite procedure is followed in making a telephone call, so in the normal radio transmission there is also a more or less fixed procedure which covers the basic elements involved. These elements are—

(1) *The call-up.* This embodies the rules of procedure by which one station makes contact with another and prepares for the transmissions of traffic.

(2) *The order of traffic.* After contact has been established, it is necessary to determine which station is to send traffic first.

(3) *Transmission of traffic.* The traffic is transmitted according to a prescribed form.

(4) *Receipting for traffic.* The receiving station acknowledges receipt of the message.

(5) *Corrections and services.* Messages are frequently garbled because of reception difficulties or operators' errors. Thus methods are provided for the efficient and speedy correction of these garbles.

(6) *Signing off.* At the conclusion of the schedule, the two stations follow certain procedures in signing off.

b. If allowance is made for differences in language and procedure signs and signals, it will be found that the above elements are generally standard for most communication systems. The detail, however, may vary somewhat between countries and also within the military of any one country. For instance, different units may observe different rules relative to the transmission of the call or the method of servicing. This often stems from individual requirements arising from strategic or tactical situations, e.g., an air unit as against an infantry unit. Furthermore, the echelon will also alter procedures. The lower echelons will usually abbreviate their procedures as much as possible because of the necessities of time and because they do not require all the data and detail that higher echelons do. Similarly, transmissions on low-echelon nets are liable to be confusing since a number of stations are often on the air at the same time and on approximately the same frequency.

c. THE CALL-UP. The calling station usually comes on the air with a series of V's sent for tuning purposes and the appropriate calls. The calls are generally sent three times, though this number may vary. The called station replies with a series of V's and calls. If the contact between the two stations is quickly made, readability reports are exchanged. Should these reports be unsatisfactory, transmitters and receivers will be adjusted, frequencies changed, etc., until signals are readable. If contact cannot be made, the calling station may hold its traffic for a later schedule, relay it through a third station, or send it blind. In sending blind, messages are generally

REF ID:A58489

transmitted twice and at a slow speed in the hope that the called station can hear although it cannot be heard.

d. THE ORDER OF TRAFFIC. Once contact has been successfully established, it becomes necessary to determine who will send traffic first. Various methods are employed. It may be ordered, for example, that the station of higher echelon send first, or that the calling station have this privilege, or that the highest priority traffic be cleared before all else regardless of which station is involved. One-for-one procedure may be used; i.e., the calling station is permitted one message, then the called station sends one, thus alternating back and forth until one of the stations has cleared all its traffic. Duplex working may be employed when the stations have the available operators and equipment and there is a large amount of traffic to be passed by both. Four operators are required in this type of working. For example, in figure 20, Operator No. 1 at station A sends

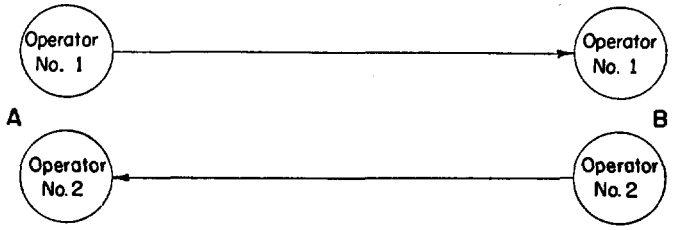

Figure 20

to Operator No. 1 at station B, at the same time that Operator No. 2 at B is sending to No. 2 at A. The chief difficulty with this sort of sending arises when No. 1 at B requires a service on a message from A. Since No. 1 at B is then using the frequency channel of the station, No. 2 at B must stop his transmission.

e. THE TRANSMISSION OF TRAFFIC. Traffic is usually preceded by a commence signal indicating that a message is about to be sent. The traffic itself is composed of the message externals and the text. The message externals contain such items as message numbers, file date and time, group count, addresses, routing instructions, precedences, and similar data. These externals may either precede or follow the text (preamble and postamble) or may be split between the two locations. Most commonly, however, these data appear in the preamble position. The text may be transmitted in code groups of letters, numbers, or both, or in plain text. In the case of coded traffic there are often signals indicating the end of a line and page of text as a check for the receiving operator. Signals usually appear preceding and following the text, the former separating the preamble from the text, the latter indicating the end of the message.

f. RECEIPTING FOR TRAFFIC. After the transmission of a message,

REF ID:A58489

the sending operator waits for a receipt from the receiving operator. This is generally rendered as simply "R". There are also procedures for provisional receipts and other special forms. In some cases, time of receipt may be given following the receipt sign.

g. Corrections and Services. A variety of methods are employed for the servicing of traffic depending on the nature and magnitude of the difficulty. A missed digit, for instance, may be serviced immediately; on the other hand, if a group were omitted this would not be known until the conclusion of the message and might be serviced at that time or might be held until all traffic has been sent. This latter procedure is fairly common, since it is convenient to transmit all traffic without interruption and then to take care of all necessary servicing. Some methods of servicing follow:

(1) *Break-in procedure.* When reception between two stations is good, "break-in" procedure may be used for quick servicing. It is useful only for minor corrections such as garbles caused by a moment of static, is very fast, and calls for alert operating.

A.	6403	3661	9626 - - -	
B.	2			B sends "2" as it is the last number he received correctly.
A.	26	8139	5560	A picks it up from 2.
or:				
A.	6403	3661	9826 - - -	
B.	(Merely depresses his key)			
A.	9826	8139	5560	A re-sends the last group and continues.

(2) *Correction of error (U. S. Army procedure).*

A.	QXTU SRV SRWP TSTL	EEEEEEEE	Actually eight or more dots indicating that "V" is in error.

(3) *Repetitions (U. S. Army procedure):*

A.	IMI	3–6 to 8 K	Repeat groups 3 and 6 to 8 of last message.
B.	3–LAJY–6 to 8– MUCU KAWC GUXO K		

(4) *Verifications and corrections (U. S. Army procedure).*

A.	J 271545 Z	3–6 to 8 K	Verify and repeat groups 3 and 6 to 8 of message filed at 271545 Z.
B.	C 271545 Z 3–LAJY– 6 to 8–MUCU KAWC GUXO K		

(5) *RQ's and BQ's.* Services which are more complex than the types noted above are usually sent as short messages. A request for

REF ID:A58489

service in international procedure is preceded by the sign "RQ", the reply by "BQ". Services which relate to cryptographic features, however, are generally sent as regular encrypted messages.

h. SIGNING OFF. When there is no further traffic to be transmitted, or at the end of the schedule time, the two stations will sign off. Usually, each station sends the "I have no more traffic" signal and then the "sign-off" signal. In many nets, the time of the next schedule is included just prior to the sign-off. These times may be enciphered for security purposes. Stations in lower-echelon nets will often sign off in order. An example from U. S. Army procedure follows:

A.	2SN	V	6F2	QNW	K	"2SN" is net call. QNW is the "close down" signal.
B.	6F2	V	G94	R	AR	
C.	6F2	V	KFR	R	AR	

19. Chatter

Radio operators, particularly the lesser-trained and on the lower echelons, exhibit a disposition to chatter amongst themselves. This chatter is the source of much information of value. It does not fall into the categories discussed above as it may relate to anything from discussions of personal problems to mentions of units or cryptographic features. This sort of talk is forbidden since it represents not only idling but a serious breach of security. Nevertheless, depending on the degree of discipline, it will occur in some volume in almost every radio net.

20. Plain-language and Low-grade Cipher Messages

Very often the error is made of transmitting, in plain language or low-grade cipher, messages which are apparently of no analysis value, yet when properly used prove of enormous assistance in the traffic analysis processes. Such messages may involve personal items or routine affairs which serve to reveal such important data as personalities, units, and locations. This type of traffic is particularly prevalent in the lower units where speed may be of the essence and where it is cumbersome to use complex cryptographic devices. Radio station personnel also indulge in this practice for exchange of technical data. They often find it necessary to ask, or reply to, questions of a semi-secret nature relative to their own operations. For this purpose, they may not use a standard system which would involve the delay of the code room and message center, but instead devise their own relatively simple ciphers.

REF ID:A58489

Section IV. THE MESSAGE EXTERNALS

21. Usual Components

a. In order to insure the proper handling of messages in both the message center and the radio station, some information must be sent in the clear or in simple code relative to message routing and accounting. This information is usually embodied in the preamble or postamble although, in some instances, it may be buried in the text. It may include any or all of the following items:

(1) Serial numbers, such as radio station numbers, message center numbers, etc.

(2) Group count.

(3) File date and time.

(4) Routing systems which serve to indicate message centers or units of origin, destination, and sometimes relay points of traffic. Distinction is also often made as to action and informational destinations. Routings may be in plain language, code, and/or cipher.

(5) Addresses and signatures, either in clear or cryptographed.

(6) Priorities, indicating the transmission and delivery precedence of traffic.

(7) Special instructions, as "time of receipt requested," "personal," "service," "repeated message," "relay message."

b. As a general rule, high-echelon traffic will contain most of these items, low-echelon traffic will cut them to a minimum. Their uses, positions, and surrounding procedure vary considerably according to communication system.

22. Serial Numbers

a. Serial numbers appearing on traffic may be enciphered or unenciphered and may represent any of the various stages through which the message passes before it is actually transmitted. The serial number acts as a reference to the message, and generally there are as many numbers in the externals as are necessary for convenient reference. The points at which such numbers may be attached to the message are—

(1) *The writer.* The writer of the message may have a personal series of numbers allotted for his use. Usually, however, numbers of this type, if present, will be included in the text.

(2) *Message center.* The message center of the unit in which the message originates generally assigns it a number. A number of this nature, if used, will usually remain constant through various relays of the traffic as it is the basic reference.

(3) *Signal center.* At large locations, several unit message centers often forward their traffic to a central signal center. The signal

REF ID:A58489

center also gives a number to the message. This number may appear in place of the message center number, along with it (though this is rare), or it may not be included at all. It is often difficult, where only one number is transmitted, to determine whether it is a message center or a signal center number.

(4) *Code room.* The code room, whether located in the message or signal center, may add a number to the traffic. Again this number may replace, or be used along with, the other types.

(5) *Radio station in-desk.* Each radio station maintains some form of in-desk for the handling of incoming messages and their routing to the proper radio positions for transmission. Here, too, a number may be put on the message. There may be several such desks for the forwarding of different types of traffic and this may result in several different series of numbers. In relayed traffic, these numbers (as well as the type included in (6), (7), and (8), below) may accumulate on the message, or a new one may be substituted for the old on each retransmission so that only the latest number appears.

(6) *Transmitter.* A number is often put directly on traffic by the radio operator as his reference. This number may be assigned in different ways. One method is to allot a series of numbers to a transmitter position and regardless of the receiving station this series is continued.

(7) *Link.* A second method is the employment of a link number, i.e., separate series are allocated for each station worked.

(8) *Operator.* A third system is the allocation of a personal series of numbers to each operator. A diagram of the above possibilities is given in figure 21.

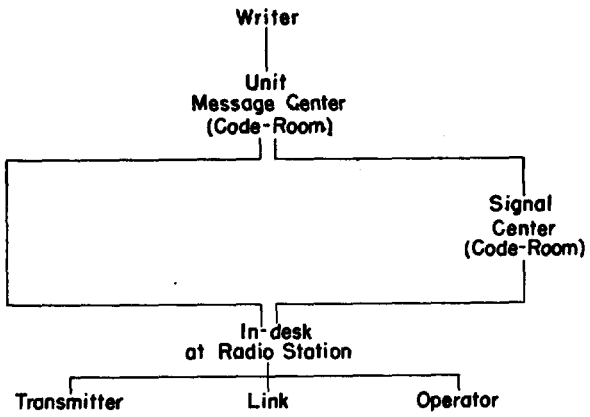

Figure 21

b. As a general rule, not more than two numbers will appear in the message externals, one representing some stage of the message or signal center phase, the other the radio station phase. In the lower

REF ID:A684682

echelons often only one number is used since the whole operation is usually so small that these fine distinctions lose much of their significance.

c. Series of numbers are allotted in some organized fashion, though this fashion may differ from net to net and from unit to unit. The series may be allocated in block form, e.g., 1 to 100 or 501 to 1000, etc. The blocks may be used until completed and then started over again; or the series may begin over on a periodic, such as a daily, basis, but if the prescribed limit is reached within the period, it is likewise recommenced. The series, on the other hand, may be open-end and repeat only at the close of a fixed period as a week, a month, or a year. In some types of series, the date or similar feature may be incorporated in the number.

d. These numbers may be enciphered in order to conceal the volume of traffic passed. It is not likely that this would be done with any of the radio station numbers because of the complexity of the operation, but it may be done at message center or signal center level. In this procedure, the plain text numbers run in serial order and messages are filed in the sending center by it. Another center referring to a specific message would do so by the enciphered number, the sending unit would then decipher same and locate the traffic. Thus, it is not necessary for the receiving center to know the system of encipherment and this permits considerable latitude in the employment of enciphering methods between the various centers.

23. Group Count

The group count may cover only the text of the message or it may include both externals and text. In some types of preamble separate counts are given for each. The group count may represent either the number of cryptographic groups, number of plain language words, or the number of individual letters and/or digits according to the method used.

24. Date Time Group

The date time group appears in the message externals and is expressed in six digits followed by a time zone suffix. It is intended to indicate the time the message was authorized for transmission, but may be used to indicate the time the message was filed at the message center, signal center, or at the radio station for transmission. Time is expressed in terms of the 24-hour clock and may be based on Greenwich Mean Time or on some local time zone. Whatever the base, it is generally kept standard for the entire net, if not for the entire communication system, regardless of the geographical area covered.

RECD 10 : AD684682

25. Routing Systems

a. GENERAL. Some method is required on radio traffic to indicate points of origin and destination and, in many cases, relay points. These methods must be relatively simple as they are designed chiefly as an aid to radio station personnel in the routing of messages. In this respect, it is necessary to understand the distinction between the routing designations and the addresses when both appear. The routing designations usually refer to message or signal centers, the addresses to specific units or persons. (There is nothing to bar the use of routing designations for specific persons but this is not generally the case.) It may be compared with the address on a letter, the routing designation representing the city of address, the address representing the company or person. On high-echelon traffic this difference is generally made, but in low-echelon traffic the routing designation often suffices for both purposes since message centers are small and traffic is almost always intended for the commanding officer. Thus, addresses as such do not usually appear on messages at this level. This distinction similarly holds true for routing designations used to indicate origin and signature.

b. The discussion of routing systems has been divided into two portions, the first dealing with the composition of routing systems, the second with their use.

(1) *Composition of routing systems.* Routing systems may be divided into three main types, plain text, call sign, and code. Plain text is seldom used on military nets because of its insecurity. Thus, generally, either the call signs of the stations are used for routing or a separate code is set up for this purpose. A routing code usually consists of two parts: code and syllabary. The code is composed of short number and/or letter combinations which may represent a location, message center, or unit. The syllabary provides code equivalents for the spelling out of place names or units not provided for in the regular code. These codes are usually rather simple, often being one-part in nature so as to be convenient for application. In some cases they are not used for security reasons, but rather for brevity. Generally, however, they serve both purposes and an encipherment of the code may be a feature of a few of these systems.

(2) *Use of routing systems.* Methods of using routing designations and the placement of these designations on traffic vary to a considerable extent. It may be set forth as a cardinal principle, however, that in most systems routing designations are used only when absolutely necessary. This increases their security and also makes it more difficult for the traffic analyst to determine the origin and destination of a message. On traffic which is point-to-point in nature, therefore, there are usually no routings at all. For example, in figure 22, A has a message for B. This message will be transmitted over

REQ: DD: AD684639

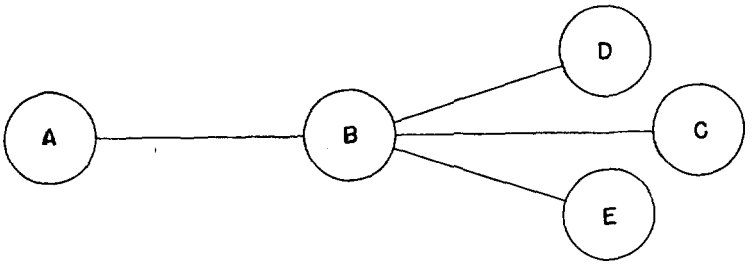

Figure 22

the A-B link and since it has originated with A and is destined for B, routing designations are not required. On the other hand, if A has a message for C, this is generally indicated in the externals so that B knows that it is to be forwarded. (It should be remembered that it is always possible to bury routing instructions in the text, but this is, as a rule, not done since it would necessitate the decoding of the message at each stage of the transmission.) This may be handled in two ways. The message may carry the routing "A to C," or it may only carry "to C" with the originator omitted. When the message is relayed from B to C, it may state "A to C," "from A," or have no routing at all. In some systems the relay point is noted, as "A to C through B."

c. Messages to several addressees can be indicated in several ways. For instance, in figure 22, A may originate a message for B, C, D, and E. All of these destinations could be incorporated in one preamble, "A to B, C, D, and E," or a separate preamble could be added at the end of the message for each location. Thus, the preamble preceding the message may carry no routing since it is being forwarded direct from A to B, but each of the preambles following the text would note "A to C," "A to D," "A to E." When this message reached B, B would transmit a copy with the proper preamble to each of the stations indicated. In this manner each copy would be numbered separately; in the single preamble method, only one message number would appear for all the recipients. It is further to be observed that if various specific addresses at one location, or routing designation, were involved, it would be possible to handle it in either of these ways or to indicate the addresses internally.

d. Distinction also may be made externally as to information and action destinations by the use of appropriate procedure. For example, in U. S. Army procedure, "W" is used to separate action from information addresses, e.g., "ABC W XQR" where ABC is the action addressee, XQR the information.

REF ID:A58489

26. Addresses and Signatures

Addresses and signatures may or may not appear externally on messages. Very often it is standard procedure to conceal them as part of the text. When they do appear externally, however, they are usually encoded and/or enciphered by means of complex cryptographic systems since they contain the specific names of units and persons and thereby are of high intelligence value. The address, unless it is in simple cipher or plain text, is usually considered a cryptanalytic, rather than a traffic analytic problem. Nevertheless, there are some features of the address and signature, such as length and manner of encipherment, which are of interest and use to traffic analysis.

27. Precedence Indicators

a. In order to insure the most expeditious handling of important traffic in both message center and radio station, some means of designating such traffic through the use of precedence indicators is usually devised. The precedences may be in the form of plain text, abbreviations of plain-text words, or number or letter code groups. Furthermore, in some military systems, these code groups may be enciphered.

b. The number of precedences used varies considerably from one nation to another and may range through several classifications of high priority to routine and deferred. There is, very often, no precedence designated "routine" and messages in this category, which are generally the most numerous, carry no marking at all.

28. Special Items

There are a great number of special items which are often included in the message externals. Some of the more common follow.

a. Part Messages. Long messages are usually broken up into several parts for ease of handling or for reasons of cryptographic security. Indications of this may be transmitted in the preamble.

b. Message Type. Indicators may be included to designate the type of message, for example, service, air warning, personal, weather, practice, repeated message, etc.

c. Miscellaneous Items. Procedures may also be provided for the transmission of miscellaneous items such as, "Time of receipt requested," "Each group sent twice," "Message sent blind," "Text in five (5) digit groups," "Relay message."

29. Message Examples

The elements discussed in the preceding paragraphs appear in message preambles and postambles in fixed positions according to the

REF ID: A5384682

procedure prescribed. These procedures differ from country to country and also often from one branch of service to another and from one echelon to another. Examples taken from U. S. Army procedures follow:

a. AB9 V PT3 291155Z GR12
BT Text
BT 291155Z K
AB9—Receiving call and destination.
PT3—Transmitting call and origin.
291155Z—File date and time, repeated as postamble.
GR12—Group count.
BT—Break before and after text.
K—"Go ahead" sign sent after message.

b. 3XF B79 V FR8–O–P B79–T–RST–A–FR8
152312Z 3XF RST B79 GR 19
BT TEXT.
BT 152312Z K
3XF B79—Multiple call-up; receiving calls.
FR8—Transmitting call.
O–P—Operational priority. (Precedence designation.)
B79–T–RST—B79 to transmit message to RST.
A–RF8—Denotes origin.
152312Z—File date and time.
3XF RST B79—Action destinations.
GR 19—Group count.

c. A45 BR6 B STX P–A45 BR6–T–N–A45
A–79K 011046Z A45–W–F2P SLW BR6
GR 28
BT TEXT.
BT 011046Z K
A45 BR6—Multiple call-up; receiving calls.
STX—Transmitting call.
P–A45—Message is priority to A45 only; to others routine.
BR6–T–N–A45—BR6 is to relay to all destinations except A45.
A–79K—Originator of message.
011046Z—File date and time.
A45—Action destination.
W–F2P SLW BR6—Denotes information destinations.
GR 28—Group count.

Section V. TEXTUAL FEATURES

30. General

While textual features and cryptographic systems are chiefly the field of the cryptanalyst, the traffic analyst should also understand

REF ID:A58489

certain aspects, both for the purpose of assisting in his study of communication nets and in the accomplishment of his responsibility to the cryptanalyst. These aspects relate to the distribution, use, and identification of systems, and to the use of indicators.

31. Distribution of Systems

Many cryptographic systems are limited in distribution; this limitation constitutes a cryptonet. For example, a system may be distributed only to the corps headquarters of a theater. These corps then are a cryptonet. Or it may be given only to units along a line of communications. There may be several reasons for the delineation of these nets but the chief ones are security, the nature of the system involved, and the physical problems of distribution. Forward units, for instance, are generally furnished different systems than the rear echelons because first, they are more liable to capture; second, they cannot handle the more complex methods of encipherment; and third, their traffic does not require the same degree of security. Within the higher echelons, divisions are made to prevent the overuse of any one system and thus deny depth. Such divisions also arise from the major break-down in command which allows some latitude in the composition of codes and ciphers to individual services or units. Furthermore, special systems may be prepared for use in particular operations where a high degree of security is desired. The important point, however, for the traffic analyst is to think of cryptonets not in terms of locations, but in terms of order of battle units, and to recognize the exact relationship existing between a system and a unit or group of units. It should also be observed that the existence of cryptonets necessitates the re-encrypting of traffic which passes from one net to another.

32. Use of Systems

Many times cryptonets will exhibit another distinguishing feature. This feature concerns the use of the system. For example, a system may be used only for confidential material, or only for secret material; or it may carry only information about supply, or shipping, or personnel, or operations. Again, this distinction is of high traffic analysis value and provides, as well, assistance to the cryptanalyst.

33. Identification of Systems

Some external feature usually appears in the text of a message to designate the system used. Where only one system of a given external appearance (as 4-letter, 5-digit) is used between two correspondents, this is not necessary, but in most instances, this designation is required and it can be accomplished in two main ways. The first is

REF ID:A5384682

the use of the form of the message itself. For example, the last group of the message may contain a repeat of the group count or the indicators may be peculiar in their formation, or they may be placed in a unique position. Any distinction of this sort will serve. The second method is the addition of a discriminant to the message, generally as a part of the text, most often as the first group. This discriminant is usually composed in a distinctive manner, as five like letters, repeated digraphs, ascending or descending numbers. It may be enciphered. Where a discriminant is lacking, it is often the task of the traffic analyst to determine means of identifying systems and to isolate homogeneous traffic.

34. Use of Indicators

The difference between the discriminant and the indicator should be understood. The discriminant identifies the general system used, while the indicator provides the specific key for decipherment. These indicators are often in the clear and, if they display any peculiarities of use, they become a valuable traffic analysis weapon. The pages of a one-time pad, for example, may be applied in order and the page indicators will thus reflect the number of messages enciphered. The pad numbers themselves will also be of value since each pad will be limited as to its users.

35. Practice Traffic

When new nets are being established, or operators are being trained, practice traffic is often devised for exercise purposes. Sometimes special nets are set up to this end, and they carry nothing but practice material. On the other hand, certain schedules may be set aside on regular links.

36. Control Traffic

In order to mislead enemy traffic analysts, control traffic may be used. Such operations may range from the formation of dummy nets to the passing of dummy traffic over the usual links. Control traffic can be employed merely to hide an operation through maintaining a volume level on all nets, or it can be used deliberately to deceive by creating high volumes at points of slight military activity.

Section VI. COLLATERAL MATERIAL

37. General

Aside from the usual intercept material discussed in the preceding sections, there are many other sources of raw data which are of value to traffic analysis. They may be divided into two groups, the first

REF ID:A58489

directly related to intercept, the second more or less miscellaneous in nature. The first group includes direction finding. The second is concerned with the study of nets other than military, the use of decode material, intelligence reports, prisoner-of-war reports, and captured documents. With reference to this second group, it should be observed that traffic analysis, in both its analytic and applied phases, often involves the fusing of information and material of all types and from all sources toward the production of a complete communication picture. In this respect, traffic analysis touches to some degree upon almost every phase of intelligence, and to a great degree upon every phase of signal intelligence.

38. Direction Finding

a. Direction finding (D/F) is a method of locating radio stations through use of specially constructed receiving antennae. These antennae register the direction along which a radio signal is travelling as it passes on a great-circle path through the D/F location. When the direction of a radio signal is determined at more than one D/F site, the location of the transmitter may be plotted by noting the point at which the bearing lines intersect (fig. 23). A location determined in this manner is called a "fix."

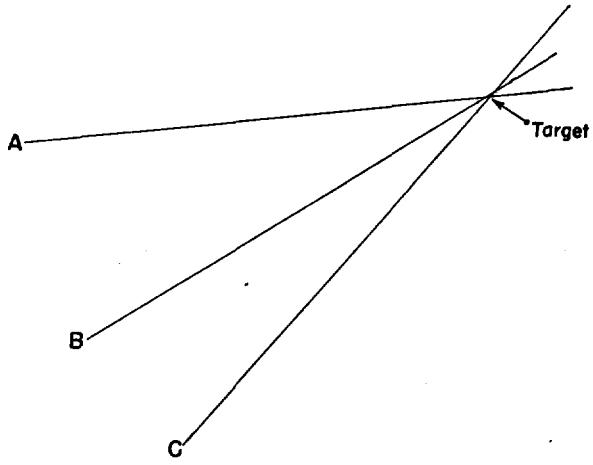

Figure 23

b. Usually, bearings will not yield a perfect fix, but will, depending on a number of factors, give a more or less restricted area. These factors include (1) the distance from the D/F station to the target, (2) the number of D/F stations involved in locating a target and the number of bearings taken, (3) the amount of the signal's deflection as encountered (for example, when the radio wave passes over mountains or shore lines), and (4) the quality of the D/F equipment.

RECD: 10 Jun 1946

Despite these and other limitations, D/F bearings seldom are misleading because the D/F operator is able to recognize whether or not a bearing is reliable and furnishes an evaluation of each bearing as it is forwarded to the plotting unit. The plotting unit also is in a position to make an accurate judgment on the reliability of a fix. An adequate arrangement for accurate direction finding requires a number of D/F stations (at least 3) located along a rather broad base (relative to the distance from the target) and so connected that they can all listen to the same signal and take their bearings simultaneously. It should be noted that D/F is particularly useful in low-echelon traffic analysis, but that over distances running into the thousands of miles it loses much of its effectiveness.

39. Information Derived from Cryptanalytic Results

Cryptanalytic solutions of traffic furnish, very often, the relationship between nets and order of battle. Since this is one of the ultimate goals of traffic analysis, detailed study of all solved messages, against the background of the nets, is a necessity. Study of solved messages should also be carried on for the purpose of relating internal information to external characteristics. This has an application to cryptanalysis for the identification of crib messages and to intelligence for the determination of the significance of traffic contacts and patterns. Message plain texts also yield a certain amount of signal information, as station locations and data concerning calls, frequencies, and schedules.

40. Intelligence Reports

Intelligence reports may vary from predigested order of battle lists to raw materials, such as captured documents or prisoner of war reports. Order of battle is the basis for the entire radio network and for the traffic passed over it. As such, an understanding of the order of battle is the necessary foundation for traffic analysis and its cryptanalytic and intelligence applications. The relationship is a circular one—intelligence added to traffic analysis yields additional intelligence. Aside from the broad phase of relating nets and battle order, this integration has specific applications in the analysis of traffic contacts and patterns and in the study of the uses of cryptographic systems and the transmission of routine messages.

REF ID:A58489

CHAPTER 3

RECONSTRUCTION OF THE RADIO NETWORK

Section I. INTRODUCTION

41. General

This chapter is concerned with the first objective of the traffic analyst, that of the reconstruction of the radio network. There are two phases to this objective, analysis of radio operations and net reconstruction.

42. Analysis of Radio Operations

This phase involves the identification and study of the elements discussed in the preceding chapter. It includes the identification of all components of the transmission, the analysis of their use, and the determination of their operating data.

43. Net Reconstruction

The nets are reconstructed coincidently with the study of radio operations. Each task helps the other; the distinction made here is only for academic purposes. In actual practice, attack must be carried out on all elements simultaneously, so far as possible, because analysis depends on the perception of relationships. Net reconstruction is concerned with the grouping of stations into nets, the determination of the links operating between those stations, and the identification of the stations with geographic locations, culminating in the production of the net diagram. The pertinent features of radio operations, such as calls, frequencies, and serial number blocks, may then be added to this diagram to complete the "pure" traffic analysis picture. The superimposition of the cryptonets and order of battle on the diagram is discussed in later chapters.

Section II. ANALYSIS OF RADIO OPERATIONS

44. Frequency Analysis

The main objectives of frequency study are (1) the determination of the system of use and (2) the solution of the system of allocation,

899152 O - 50 - 7

REF ID: A684682

including the method of original assignment, the pattern of rotation, and the reconstruction of the basic charts involved.

a. ANALYSIS OF THE SYSTEM OF USE. (1) The chief problem in the study of the system of use is the determination of accurate basic data. Once these data have been properly recorded the conclusion will usually be apparent. The basic data consist of who sends to whom and on what frequencies. To simplify study, a rough circuit diagram may be prepared. Two examples of these data and the conclusion to be drawn are given below.

(*a*) In the following example the net is a free star (fig. 24):

A to B on 5,000 KCS.
A to C on 5,000 KCS.
B to A on 5,000 KCS.
B to C on 5,000 KCS.
C to A on 5,000 KCS.
C to B on 5,000 KCS.

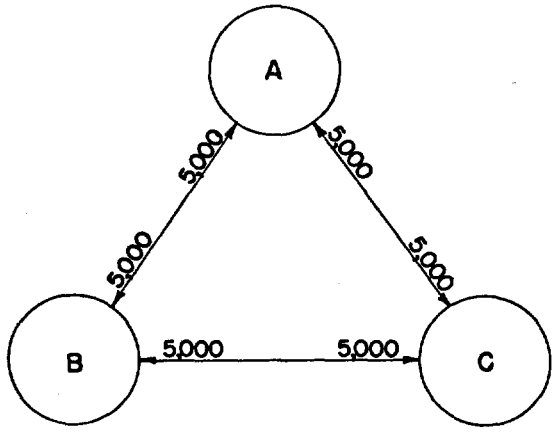

Figure 24. The net is a free star.

(*b*) In the following example the net uses the complex-sending system (fig. 25):

A to B on 5,000 KCS and 10,500 KCS.
A to C on 5,000 KCS and 10,500 KCS.
B to A on 4,000 KCS and 7,500 KCS.
B to C on 4,000 KCS and 7,500 KCS.
C to A on 3,000 KCS and 6,000 KCS.
C to B on 3,000 KCS and 6,000 KCS.

REF ID:A58489

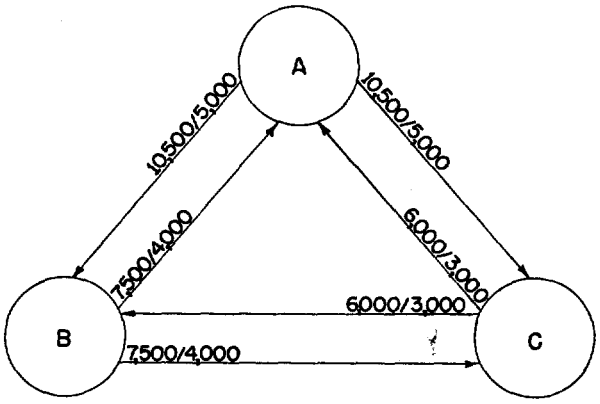

Figure 25. The net uses the complex-sending system.

(2) Arriving at accurate data, however, is often a fairly difficult task. It requires a detailed study of chatter for at least a week's period and usually somewhat longer, depending on the completeness of coverage during the period and the complications involved in the use of the frequencies. It is well to mention that, for the analysis of many features of radio operations, it is often desirable to have complete cover on a net for a limited period, such as a day, than to have spotty cover over a longer time. Generally, however, cover will be incomplete, that being one of the reasons why careful study of chatter is necessary before a decision is reached. A second difficulty arises where the enemy stations drift from the assigned channel. For example, a station allocated 4,650 kcs may vary all the way from 4,600 to 4,700 kcs. In the case of simplex and star working, much of this variation is intentional so that the one station can reply a little off the correspondent's frequency. A third problem is created by the assignment, as sometimes happens, of four or five or more wave lengths to a station. These wave lengths are not restricted to fixed times of day, but the station is at liberty to use whichever one can best be heard. It should be pointed out that there will often be exceptional uses of frequencies which cause the net to vary from its basic form of working. These exceptional uses should be carefully studied and explained, but they should not be considered as changing the net type.

(3) To illustrate some of these problems, assume that a cursory examination of a week's transmissions reveals the following:

A to B on 5,000 KCS, 11,600 KCS.
B to A on 5,000 KCS, 7,000 KCS, 11,590 KCS.
A to C on 5,000 KCS, 5,500 KCS, 11,625 KCS.
C to A on 5,010 KCS, 5,025 KCS, 6,995 KCS.

REF ID: A584682

B to C not heard.
C to B not heard.

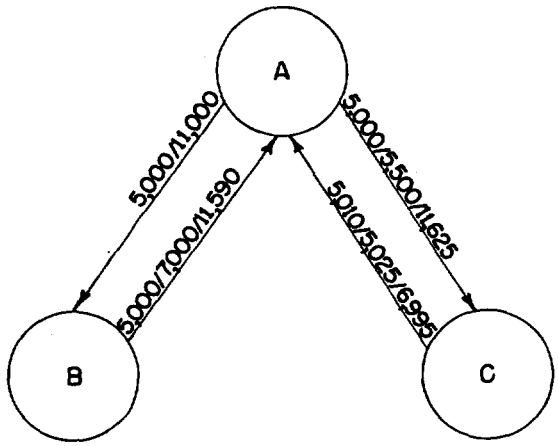

Figure 26.

The net, at first glance, appears to be a star (fig. 26) though there are several discrepancies to be explained. It may be assumed that C's 5,010 and 5,025 kcs are drifts of the base frequency 5,000 kcs, that A's 11,600 and 11,625 and B's 11,590 should all be 11,600 and that B's 7,000 and C's 6,995 are both 7,000. However, A uses 5,500 kcs to C, but neither B nor C have been heard on this frequency. This runs counter to the principle of the star. A check is made of the appearance of 5,500 kcs and it is found to have been used twice during the period under study, both times under the same circumstances. A came up on 5,000 kcs, C reported interference on this frequency, and A switched to 5,500 kcs. It is likely, then, that 5,500 kcs is an extra wave length assigned to the net for emergency purposes and that, in time, the other stations will also make use of it. In this instance the net is not working star since 5,500 kcs at A is corresponding with 5,010 kcs at C, but it is known that A did try to make contact under the established procedure first, so that this becomes the exceptional case and does not contradict the theory as to the star form. The 7,000 kcs at B and C also create a problem since A has never used this frequency. Again reference is made to the chatter logs where it is discovered that this frequency is used during the evening hours and has been heard once from B, twice from C. However, on all three occasions the A end of the circuit was not heard at all. It is possible that A was up on this approximate wave length but, because of some propagation or reception peculiarity, the intercept station was unable to hear it, or that the intercept station, for one reason or another, may only have been

REF ID:A58489

able to cover one end. Whatever the reason, imperfect coverage is apparent and, until A has been monitored on this schedule, nothing can be determined which would affect the star hypothesis. The net picture, as mentioned above, indicates that the star is controlled rather than free since B and C have not been observed in contact. Study of chatter, however, casts some doubt. At one point, A has asked B for a special schedule at 1500. B replies he cannot make it then since he has a schedule at that hour with C. On another occasion, A sends two messages to C for relay to B, A stating he has not been able to contact B. This chatter suggests that B and C work each other and that the net is a free, rather than a controlled, star. The evidence is slim since the schedules mentioned in the chat may only have been emergency ones, but it is sufficient to justify reserving decision and waiting for further developments.

b. Solution of the System of Allocation. Solution of systems of allocation requires at least several months of observation and, if some complex method of rotation is involved, may run into much longer periods. The problem is twofold: (1) the method of basic allocation and (2) the method of rotation, if present.

(1) It should be stated at the outset that usually a method of basic allocation will not be used except as it is tied into a system of rotation. Where frequencies are fixed, they have generally been assigned because they can be heard between two points and because there is no interference from other frequencies. This is particularly true on high-eschelon nets. It is always worthwhile, however, to check the frequencies of the various nets of a radio network for characteristics, if only to be sure. Some pattern may appear, for example, air-ground nets, wherever located, may be restricted to a definite set of frequencies, or divisional nets may be limited to a certain band. Anything in the way of a pattern, naturally, is possible. A tabulation of frequencies against net and the seeking of relationships in frequencies between related nets should serve to reveal most such patterns. Related nets may be so determined on the basis of function, such as air, shipping, line of communications, divisional artillery, by echelon, or by command.

(2) Whether a frequency system is fixed or changing, and if changing what the period of change is, can be discovered merely by observation. If a changing system is used, the first step in analysis is to determine some method of maintaining continuity so that if station A transmits on 4,300 kcs one day and 3,750 kcs the next day, there is some way of knowing that 4,300 and 3,750 are both the same station. Continuities may be established in two main ways:

(*a*) *Characteristics of radio operations.* Almost any item of radio operations may serve the purpose:

RECD 10 : AD684682

1.

Calls. If frequencies change and calls do not, identification is a relatively simple matter.

2.

Schedules. Taken in conjunction with other data, schedules may provide a clue to continuities. They are likely to be characteristic for the stations of a net, but care must be exercised in the use of this technique and supporting evidence should always be present. Also of value is any mention of future schedules at the time of the sign off, for example, "QRX 0100" (next schedule at 0100). It is then possible to relate stations heard at 0100 on the following day back to the stations involved in the chatter.

3.

Serial numbers. If serial numbers do not begin over at the time of each frequency change, they may be utilized. In the case of message center serials, care must be exercised to avoid the use of relayed traffic. For example, in figure 27, A, on the 15th, may

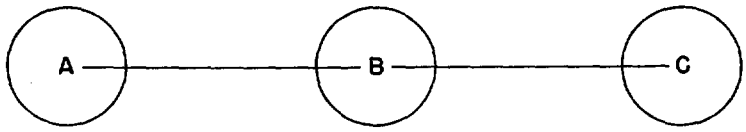

Figure 27.

send a series of messages over the A–B circuit with the message center serial range 1544–1573. On the 16th, the entire net changes frequency, and several messages are intercepted with the routing instructions A to C and the serials 1578–1581. It cannot be assumed that the new frequency heard on this transmission is at A since the traffic might have been passing on the B–C link. If some of the traffic, however, was routed A to B or else carried no routing indicating a local message, then the continuity might tentatively be established. Of far greater value in this respect are the radio station members, and, except in the case of the in-desk number where it is possible for several different circuits to be transmitting the same series, these ranges are reliable. Where serial ranges are fairly distinctive they may also be used in reverse. For example, station A may receive traffic in only a certain message center serial range from a correspondent. This may be caused by the fundamental assignment of the range to a definite service, for example, supply. Station A is at a quartermaster depot; consequently all the traffic to A from the correspondent will be in the one series.

REF ID:A58489

4.

Routings. Routing codes can also be of value when used by nets. It may be assumed that, as a general rule, a radio station will originate and receive more of its own traffic than it will handle on relay for other stations. For example, station A is at Gettysburg. If A changed frequency daily, it could probably still be spotted because of the large amount of Gettysburg correspondence transmitted and taken.

5.

Routines. Because of the requirements of military operations, it is necessary for units to make routine periodic reports. Very often these reports can be identified because of the stereotyped nature of the message externals. For example, a situation report, or a strength report, may be sent from station A to B, C, and D each day at approximately 2000. It would be a relatively easy matter to watch for this report to pass and to identify it purely by these external characteristics. Such routines furnish a trade-mark for the originating station and can be discovered and utilized without any knowledge of the text.

6.

Cryptographic systems. Cryptographic systems which are unique to certain correspondents can likewise be used as identifications. This also holds for some of the cryptographic features such as pad numbers of one-time pad systems. The 10th Division, for example, which sends through station A, is enciphering its traffic in pad number 1234. Usually, only one originator is permitted to encipher messages in a given pad because of its one-time nature. There may be one or several holders who can receive. Thus, until completely used, the pad will identify the originating station and, in some cases, also the recipient. Caution must again be exercised, however, with regard to relay messages and to the possi-

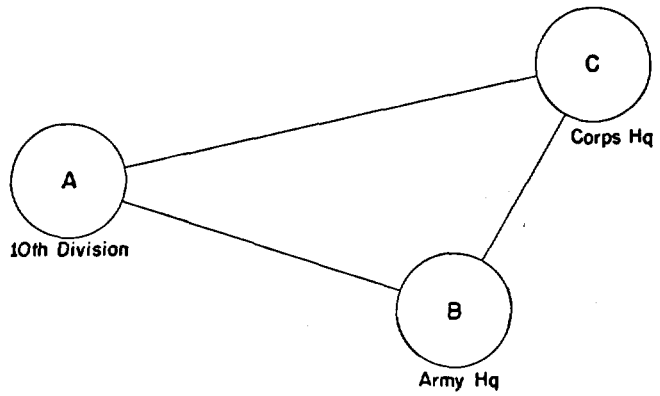

Figure 28.

REF ID:A5384682

bility of this traffic being transmitted over a different circuit of station A. If, for instance, the pad is used between the division and headquarters for some special purpose it could pass by several different paths (fig. 28). According to which route is available or readable, 10th Division's traffic may go directly to Corps or be relayed through Army.

7.

Services. Messages transmitted on one day may be serviced at some later date. If the date span bridges the frequency change, it may be possible to determine continuity.

8.

Chatter. Items of chatter often serve continuity purposes. Names of radio operators, for instance, may be observed in chatter, and, on recurring after a change, act as an identification.

9.

Procedural peculiarities. Some stations and operators develop unique habitual procedures which mark them. A station might, for example, regularly misspell a place name, or transpose the digits of a routing code number because of an error in the chart; an operator might send his call signs four times instead of the three used by others on the net, or send a separator between the hours and minutes of the file time though no one else does. Such peculiarities, which often arise from personal quirks, are usually rather difficult to discover because they involve painstaking attention to detail, but they are well worth the trouble. It is one of the phases to which the intercept operator, through his knowledge of the usual, can make an important contribution.

(*b*) *Use of direction finding.* This identification technique, described in paragraph 38, is a valuable means of providing continuities where efforts to use procedural characteristics have proved inconclusive. It is to be pointed out that, in general, procedural characteristics furnish a faster, less expensive, and more accurate method if they can be so utilized.

(3) Some of the techniques outlined above can stand by themselves, but it will always be found wise to apply several of them in combination so that one checks the other and reinforcing evidence is supplied. For example, the message center serials may indicate a continuity, and a routine message or the use of a restricted cryptographic system serves to confirm it. Incidentally, these methods of determining continuities are applicable to any sort of frequency change, whether periodic or irregular, and will also serve to tie together night and day frequencies and variant frequencies of the same station.

(4) When continuities have been established, the next task is the

REF ID:A58489

listing of the frequencies against the date breaks and the search for patterns of change or rotation. Once the general system has been solved, it will usually not be too difficult to keep abreast of changes. No attempt will be made in this manual to describe actual methods of solution further than to say that the problem, at this point, becomes one of cryptanalytic attack.

45. Call-sign Analysis

The main objectives of call-sign analysis correspond with those of frequency analysis, that is, (1) the determination of the system of use, and (2) the solution of the system of allocation.

a. Analysis of the System of Use. This analysis is conducted through a study of call signs as they are reported in the chatter. The period of call-up furnishes the most fruitful material, but all allusions to calls must be noted. A listing of the call-ups will generally provide sufficient information to identify the system.

(1) *Net using double-station call procedure* (fig. 29):

A calls B	DEF de ABC
B replies	ABC de DEF
A calls C	GHI de ABC
C replies	ABC de GHI
B calls C	GHI de DEF
C replies	DEF de GHI
B calls A	ABC de DEF
A replies	DEF de ABC
C calls A	ABC de GHI
A replies	GHI de ABC
C calls B	DEF de GHI
B replies	GHI de DEF

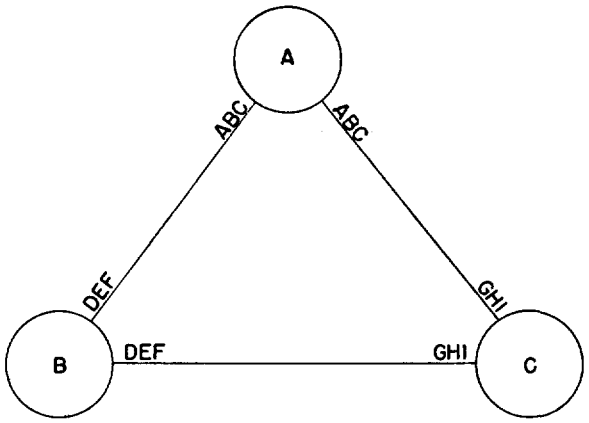

Figure 29.

(3) *Net using single station call* (fig 31)

A calls B	DEF
B replies	DEF
A calls C	GHI
C replies	GHI
B calls C	GHI
C replies	GHI
B calls A	ABC
A replies	ABC
C calls A	ABC
A replies	ABC
C calls B	DEF
B replies	DEF

REF ID:A58489

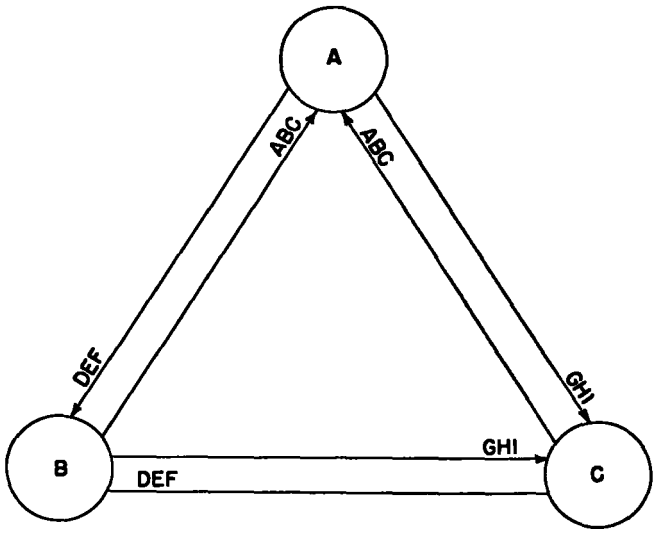

Figure 21

b Solution of the System of Allocation Like the study of frequency systems, the analysis of call sign systems may require anywhere from several months to several years Again like the frequency systems, the problem is twofold (1) the method of basic allocation and (2) the method of rotation, if present

(1) Calls must first be classified as to composition, for example, 3 digit, digit-letter-digit, etc, then these break-downs checked for pattern The allocation of calls may or may not be centralized. In the former instance, there will generally not be more than two or three systems to be solved, e g, Army and Air Force In the latter, however, depending upon the amount of decentralization, there may be a great many small systems Thus, in the initial analysis, calls should be listed by net, and the composition of the calls on each individual net observed If, for example, of all the nets under study, only two nets use 4 letter calls, it may be assumed, for the moment, that these nets employ a common call allocation After nets have been grouped by composition of calls, a search is made on each net for pattern For instance, the calls on three of the nets may carry "T" as a middle letter, indicating a possible grouping for study If a number of other nets also display similar characteristics, one using "R", another "V", etc, it is likely that all of the calls on these nets originate in the same general system The following lists of calls by net will serve to illustrate the general procedure

REF ID: A684682

Net I	*Net II*	*Net III*	*Net IV*
ABD	CDF	V7K	BCE
EFH	GHJ	V8J	KLN
FGI	LMO	X3M	OPR
JKM	MNP	Y4T	
		Y6S	

Net V	*Net VI*	*Net VII*	*NET VIII*
BAO	IJL	DEA	FQR
HIU	NOQ	HOA	JLT
KOE	PQS	JIE	SRM
MEA	STV		VTR
PAE			XOM
			XOA

(*a*) In the first quick grouping, the following division could be made:

Nets I, II, IV, V, VI, VII, VIII—3-letter.
Net III—letter-digit-letter.

(*b*) The first group then splits into three:
Nets V, VII—consonant-vowel-vowel.
Nets I, II, IV, VI—1st and 2d letters are in alphabetic order, 3d letter skips one from 2d.
Net VIII—apparently random.

(*c*) Thus, there are at least four systems of call distribution involved. On the other hand, studies of the calls on a number of nets may reveal no pattern at all. This is usually indicative of a large, general system in which control is highly centralized and the randomization carefully planned.

(2) Other features may also be employed to assist in the establishment of homogeneous call-sign systems for relationships between any of the elements of different nets that indicate possible relationships in other elements. For example, there may be some question as to whether or not the calls appearing on two separate nets can be grouped together. A cryptographic system, found nowhere else, is discovered on circuits of both nets. This suggests that there is some connection between the two nets and increases the possibility of a common call system. Procedural peculiarities of any type may likewise be used to associate nets. Order of battle, if known, furnishes another valuable method. All the nets of a given Army, for instance, will probably use the same call allocation. It may be that, in a highly centralized organization, a dichotomy can be established simply between Army and Air Force.

(3) Once the various systems have been segregated, it becomes possible to attack each separately. If a pattern exists within the call itself (as in Nets I, II, IV, and VI in (1) above), all possible

REF ID:A58489

calls can be listed and this used as a basis for the reconstruction of the allocation chart. If no pattern can be found, however, (as in Net VIII), it becomes infinitely more difficult to reconstruct these charts, and if the system is a large one it may be necessary to collect data over a period of years before a solution can be effected.

(4) Often these allocation charts serve as a base for the change or rotation of calls or for the choice of alternate calls at the same station. In analysis of the system of rotation, the first step is to determine the periodicity, which can usually be done simply by observation, and the second to establish continuities so that the calls related to each station or link and the order of their use are known. The techniques outlined in paragraph 44*b* (2) for the determination of continuities when frequencies change also apply to call signs with one exception (par. 44*b* (2) (*a*)*1*) and need not be further discussed here. In this one exception the reverse is true—if calls change and frequencies remain constant, the frequencies furnish the continuities to the calls. When continuities have been established, the calls may be listed in order for each station, and through the application of cryptanalytic techniques, the system attacked.

(5) In the practical aspects of call-sign system solution, it will be found that garbled and missed calls account for much of the difficulty in the initial stages of attack. Where there is a pattern to the call composition, garbles can be resolved with relative simplicity. In random composition, however, the problem is more complex and care must be taken to eliminate all spurious calls before beginning analysis. Garbles occur with some frequency in calls partly because the enemy makes an attempt to restrict their use, and partly because his operators become so familiar with them that they tend to send them in a quick, sloppy manner. In general, a call should be intercepted several times, preferably at different schedules, before it is accepted as genuine. Garbles can often be corrected by reference to the actual Morse equivalents. For example, if the call "AHV" has been established and the call "ASV" appears once on the same net, the Morse will indicate the possibility of error:

AHV .— ....—
ASV .— ... ...—

the difference being only a dot. Other link characteristics such as frequency, serial numbers, etc., will assist in confirming or disproving the identity of the two calls.

(6) Missed calls also present a problem to the analyst. They arise from imperfect coverage, and there is no remedy except to give more complete coverage and schedule information to the monitoring stations. Since calls are often sent only at the start of each schedule, this time is most important.

REF ID:A584489

(7) The following example, based on the call composition used in Nets I, II, IV, and VI in (1) above, will illustrate the general approach (since these calls have a definite pattern, all possible calls can be listed):

ABD
BCE
CDF
DEG
EFH
FGI
GHJ
HIK
IJL
JKM
KLN
LMO
MNP
NOQ
OPR
PQS
QRT
RSU
STV
TUW
UVX
VWY
WXZ
XYA
YZB
ZAC

(*a*) It is noted that calls change daily on the four nets involved; after the completion of one week, a tabulation by net and station can be made. (Garbled calls have been corrected.)

	1	2	3	4	5	6	7
Net I							
Station A	ABD	PQS	TUW	KLN	BCE	RSU	....
Station B	....	WXZ	BCE	EFH	HIK	....	UVX
Station C	MNP	JKM	MNP	WXZ	NOQ	XYA	CDF
Net II							
Station A	CDF	....	IJL	YZB	....	ABD	JKM
Station B	UVX	LMO	VWY	STV	JKM	GHJ	....
Station C	IJL	STV	OPR	ABD	DEG	MNP	WXZ

REF ID:A58489

Net IV

Station A	TUW	RSU	....	RSU	UVX	FGI	IJL
Station B	....	EFH	....	FGI	IJL	LMO	....
Station C	NOQ	KLN	....	XYA	OPR	YZB	VWY
Station D	HIK	XYA	....	LMO	CDF	STV	DEG

Net VI

Station A	....	ABD	DEG	MNP	PQS	BCE	....
Station B	VWY	....	PQS	TUW	....	HIK	....
Station C	DEG	YZB	JKM	GHJ	EFH	TUW	....

(*b*) Observation of the calls indicates that they are being rotated in a simple manner, and a check against the list of all possible calls shows that the difference of six between calls on the same net is fairly common. For example, on the 1st, MNP is 12 calls away from ABD; IJL is 6 away from CDF; NOQ is 6 away from HIK. It is also noted that the calls QRT and ZAC do not appear, probably to prevent confusion with Q and Z signals. This leaves 24 possible calls, and the periodicity of 6 suggests that the basic table is arranged as follows:

ABD	GHJ	MNP	TUW
BCE	HIK	NOQ	UVX
CDF	IJL	OPR	VWY
DEG	JKM	PQS	WXZ
EFH	KLN	RSU	XYA
FGI	LMO	STV	YZB

and that the calls are taken off across the chart and allotted to Net I, Net IV, Net II, and Net VI in that order. Within each net the calls are assigned to individual stations in what appears to be a random order.

46. Schedule Analysis

Schedule analysis is designed to discover what system is in use, whether the signalling is restricted or unrestricted and, if the former, what the time of each schedule is.

a. Analysis of the System. Analysis involves a tabulation of times of communication together with a study of chatter. Time is correlated with circuit and, if a definite pattern shows up several weeks running, it may be assumed that period signalling is in use. In the preparation of the data, record should be made of such chatter items as, "I have a schedule at 2200 with XYZ." Such information helps to fill in the gaps in cover. Also note must be taken of the very brief schedules where the stations have no traffic and merely call up, say, "I have no traffic," and sign off; or where a station is running over his schedule time and calls his regular correspondent

REF ID: A684682

to say, "I am busy," and then goes back to the first correspondent. If no pattern appears, however, it is then likely that either unrestricted signalling or priority signalling is in use. This can be determined by a check of the tabulation, since in priority signalling the control station will usually come up at regular schedule times. Chatter will also prove characteristic for this type of operating since the order of transmitting is fixed and usually only one message is sent at a time by each station. The type of unrestricted signaling can likewise be identified from chatter. Where arbitrary schedules are used, the stations will arrange for the next schedule at the time of sign-off. Incidentally, in period signaling, the stations also sometimes mention the time of their next schedule so care should be exercised not to confuse the two. The regular pattern of times over a long period will usually distinguish period signaling. In alert operating, no arrangements are made, all stations standing by for transmissions at any time.

b. Determination of Schedules. The tabulations made for the above purpose will also serve to determine the times of regular schedules. Each circuit may be plotted on cross-section paper with hours down the side and days across the top. This will give a month's picture at a glance (fig. 32). The letters in each square indicate

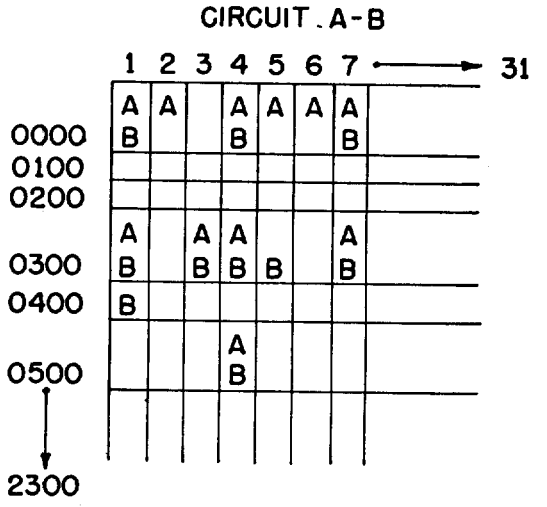

Figure 32.

the end of the circuit that was heard. On the 2d at 0000, for instance, only A was intercepted. Other items may be added to this tabulation if desired. These might include number of messages passed, indication as to which of the alternate frequencies was being used, and special notes from chatter relating to schedules. Two irregulari-

REF ID:A586489

ties will be noted in the pattern in figure 32. On the 1st at 0400 B ran over the regular 0300 schedule. Reference to chatter discloses that B asked A for additional time. On the 4th at 0500, A-B worked a special schedule. A check of chatter on other A circuits shows that A arranged for this schedule through a third station, which could contact both A and B, for the purpose of passing urgent traffic.

47. Procedure Analysis

Analysis of procedure is undertaken (1) to discover characteristics which will assist in identifications and continuities, and (2) to solve any encipherments employed.

a. Study of Characteristics. The normal characteristics of the procedure under study should first be established. This includes the call-up, exchange of readability, order of traffic, message externals, servicing methods, and sign off. In many communication systems, several normal procedures may be apparent, each representing a major division of nets. When this task has been completed, variations from the normal as applied to individual nets, groups, links, and stations must be identified. These variations may be of any sort. For example, one net may use break-in procedure for servicing, or may place the priority of the message in a different preamble position, or may tune up with a letter other than "V"; or a station may regularly place an NR before the link serial number while others do not, or fail to use an RQ before its request for services. These variations arise in several ways. They may be due to an oversight on the part of personnel, such as failing to change to a new method of procedure because of habit or because the station was not included in the distribution of the new instructions. Such situations will usually be corrected in time, or, if distribution is impossible, continue to serve as an important identifying feature. Or they may arise from the latitude permitted nets or stations in compiling their own rules. The only approach to this analysis is through the detailed study of chatter and the recording of the normal and the unusual.

b. Solution of Enciphered Procedures. The solution of enciphered procedures depends on the ability to determine the meaning of procedure signs and signals in context and, where a periodic change is involved, the equating of the same procedure in terms of different encipherments. For example, in the opening minutes of a schedule, procedures such as "Send V's," "How is my readability," "I cannot hear you," "Readability is poor," "Adjust your transmitter," etc., will be common. By study of the context over a period of time, it should be possible to identify the appropriate meaning.

RECD 100 : 2684682

48. Serial Number Analysis

The analysis of serial numbers is directed toward the determination of the type of number, the manner of assignment, the solution of any encipherments, and the identification of the series with units.

a. ANALYSIS OF TYPE. The type of the serial number, that is, indesk, message center, signal center, etc., is determined through a correlation of the numbers with other signal features. The numbers should be tabulated for a period of a week or more as necessary against call signs, file times, intercept times, cryptographic systems, routings, and similar items. The following discussion is not intended to be complete since there are so many possibilities involved in these manifold relationships, but it is hoped to give some general indications on how to think about them.

(1) Serials which run in order by cryptographic systems may be a code room number, a message center number, or a signal center number. It will rarely be a radio station number. The caution to be observed is that the cryptographic system may not be the basic factor and the serial the result, but rather the system, like the serial, may be the effect of something more basic. For example, a series is found which agrees with the cryptographic system and every message in that system is always in that series. It is noted, however, that the system is the only one held by the unit involved. Thus, both the system and the series are representative of the unit, and the number only accidentally follows the system.

(2) Serials which correlate with routings are also usually in the message/signal center phase. Sometimes several series which do not match with other features are observed originating at the same routing. These are often the expressions of several units operating through a single signal center. Such numbers may be put on at the unit message center or they may be added at the signal center, the latter maintaining several series, one for each of the units involved.

(3) Serials which run in order by file time may represent either the message/signal center or radio station stage. Usually, file times are put on at the radio station, but, since the traffic comes to the station direct from the message or signal center, its order is seldom disturbed, so that it could be numbered in one place and time-stamped in another and still demonstrate a relationship. In the case of radio station numbers, it will usually be found that several call signs, used at the same station, will run in a common series.

(4) Transmitter numbers will, as a rule, correlate with the sending call signs and the intercept time. Link serials will be evidenced by the further distinction of a separate series for each station called. Operator numbers are indicated by several series originating at one call, regardless of reply, unless the station works to only one correspondent.

REF ID:A58489

(5) It is just as important in the study of serials to have negative evidence as positive, so note should also be taken of what does not fit the series. If several routings fall in the same series, for instance, the number was not assigned at the message center if that is what the routing represents. Such a series is more likely to relate to the radio station which handles traffic for several different routings.

(6) Many times series will appear which bear a relationship to several items. It is then necessary to determine what is the basic consideration. For example, a tabulation of serial numbers reveals:

Serial	*Crypt. System*	*Routing*		*Call sign*		*File date and time*	*Intercept date and time*
		From	*To*	*From*	*To*		
326	A	A	B	PQR	XYZ	08 1040	08 1215
327	A	A	B	PQR	XYZ	.....	08 1217
328	B	A	C	PQR	XYZ	08 1040	08 1220
335	A	A	B	....	....	09 1230	09 1530
339	C	A	C	PQR	XYZ	09 1210	09 1532
340	A	A	B	PQR	XYZ	09 1235	09 1535
343	B	A	C	PQR	....	09 1300	09 1538
344	C	A	C	PQR	XYZ	09 1300	09 1600
345	C	A	C	PQR	XYZ	09 1250	09 1615
346	A	A	D	PQR	XYZ	09 1310	09 1619
362	C	A	C	PQR	XYZ	11 1240	11 1525
367	C	A	C	PQR	....	11 1500	11 1801
368	C	A	C	PQR	XYZ	.....	11 1820
429	B	A	C	PQR	XYZ	08 1100	08 1223
437	B	A	C	PQR	XYZ	09 1315	09 1623

Except for the last two numbers which are garbled, the serials correlate with origin, calls from and to, and intercept time. File time is slightly off in several places. Since intercept time fits so well, it may be assumed that this is a radio station number. Reference is now made to the circuit diagram and it is noted that PQR is on the edge of the net and that it is connected to it by the single circuit to XYZ. Thus the routing "A" is probably the only message center routing through PQR and, therefore, the relation between "A" and the serials is forced and not the true one. If it were the true one, it is likely that the intercept times would be somewhat out of order because of the routine of processing traffic and the passing of priority messages. But since there is only one link out of the station, the type of radio station number used cannot be defined. It may be an in-desk, a transmitter, or a link number. If the picture is expanded, however, to include an additional link with numbers, it will appear as follows:

REF ID: A584682

Serial	Crypt. System	Routing From	Routing To	Call sign From	Call sign To	File date and time	Intercept date and time
372	B	A	C	PQR	STN	08 0900	08 1025
733	A	A	B	PQR	STN	08 0910	08 1030
734	A	A	B	PQR	STN	08 0910	08 1033
759	B	A	C	PQR	STN	11 1535	11 1911
765	C	A	C	PQR	STN	11 1820	11 1914

The serial is a link number since the numbers run in a separate series for the PQR–STN channel.

Serial	Crypt. System	Routing From	Routing To	Call sign From	Call sign To	File date and time	Intercept date and time
603	B	A	C	PQR	MNO	171441	172010
604	A	A	C	PQR	MNO	171411	172013
605	B	A	C	PQR	MNO	171411	172016
606	B	A	C	PQR	MNO	171415	172021
610	B	B	D	GHI	STN	171430	171810
612	C	B	D	GHI	STN	171430	171812
612	C	B	D	CHI	STN	171430	171812
613	A	B	C	PQR	MNO	171440	172005
634	A	A	C	PQR	MNO	181120	181523
636	A	A	E	GHI	STN	181135	181803
639	A	A	D	GHI	STN	181150	181809
640	B	A	C	PQR	MNO	181155	181520
641	A	A	C	PQR	MNO	181155	181535

Note the correlation with file date and time and the interlocking of the call signs. This is an instance where file date and time are entered at the radio station.

(7) The following tabulation is that of a signal center number:

Serial	Crypt. System	Routing From	Routing To	Call sign From	Call sign To	File date and time	Intercept date and time
020	A	A	C	GHI	PQR	230910	231233
023	A	A	C	GHI	PQR	230910	231230
024	A	A	C	GHI	PQR	230925	231225
026	B	B	D	JKL	STN	230910	231413
029	C	B	D	JKL	STN	230915	231416
153	A	A	C	GHI	PQR	241120	241236
155	A	A	E	MNO	XYZ	241125	241228
156	D	A	E	MNO	XYZ	241130	241231
164	A	A	E	MNO	XYZ	241130	241238
166	B	B	D	JKL	STN	241145	241411
167	B	B	D	JKL	STN	241130	241402
170	C	B	D	JKL	STN	241145	241409
171	C	B	D	JKL	STN	241150	241421
172	D	A	C	GHI	PQR	241145	241250

REF ID:A58489

Both A and B route through the signal center where a common series is applied to the traffic of both. The possibility of this being an in-desk number is largely ruled out by the failure to correlate with file time.

b. Analysis of Assignment. Study of the manner of assignment of serial numbers is concerned with three phases: (1) composition of the numbers, (2) range of the series, and (3) over-all pattern of assignment.

(1) *Composition.* The numbers may consistently be two-digit, or three, or four, etc. They may incorporate such features as the date. Composition, if sufficiently distinctive, often furnishes a means of quick recognition.

(2) *Range.* The range of the series may be readily determined, or it may take several years. It can be established by observation of the reversion to the lowest number of the range, which will fix its limits in terms of either time or numbers, or both.

(3) *Over-all assignment.* Serial ranges of the same type of number should be checked for pattern of assignment against each other. In the case of message center numbers, for example, it may be found that each division of an army has been given separate blocks, 1–100, 101–200, 201–300, 301–400, etc. Similar patterns may appear with regard to signal center or radio station numbers. These patterns can be analyzed through a comparison of ranges representing groups which bear an order of battle or a net relationship to each other.

c. Solution of Encipherments. The solution of enciphered serial numbers is a matter of cryptanalytic approach. The initial break, however, can often be made by gathering a group of messages on which it is thought that the serials run in order. If, for instance, an in-desk number is involved, messages arranged by file time should assist in attacking the system. It also may be helpful to select the first message of the day, if possible, and use it as No. 1. It will serve as a base even though that may not be its actual number. If the numbers are thought to repeat daily a selection of this message each day may yield different encipherments of the same number. As a rule, these systems should not prove too difficult to solve unless the method is one of complete randomization.

d. Identification of Series. Once the type of series is known, the next step is to determine the actual unit behind each series. In the case of a message center number, for example, what message center is it? Or if there are three series of in-desk numbers out of the same station, what do each of these series represent? These identifications are established by "pure" traffic analysis plus the use of collateral material on the basis of the axiom that things equal to the same thing are equal to each other. For instance, a range of in-desk numbers appears only with codes A and B. Codes A and B are known to be

REF ID: A5384682

transportation systems. Therefore, the serial range represents the transportation unit at the signal center. Care must always be taken, in chaining data of this sort, that the basic assumptions are valid (in this case, that A and B are transportation codes) and that the things compared demonstrate an exact relationship (if A and B were also used on another range of numbers out of the same station, then it is unlikely that the first range represents transportation, but rather that it represents some other type of unit or else a specific transportation unit, these possibly being two at the station). Decode and order of battle material are invaluable in the study of these series. If some of the traffic related to a series can be read, solid evidence for conclusions is provided and often a definite unit can be identified. Order of battle will do much the same. For example, where only one air unit is carried at a given location and a series, tied to the air cryptographic systems, is observed out of that location, it may be assumed that the series represents the air unit.

49. Analysis of Priorities

The analysis of priorities is directed toward determining their order and the solution of any encipherments. The order is determined by comparing file times with intercept times. In general, the shorter the average time lapse, the higher the priority. However, time lapses should be compared within stations not between them since the size of the station and the volume of traffic handled will cause individual differences. Relayed traffic, of course, should not be included in the comparisons. The cryptanalysis of encipherments is naturally dependent on the system used, but it is of assistance to group messages according to expected priority, thus providing isologs.

50. Analysis of Routing Systems

The main objectives of routing system analysis are to discover the manner of use and to solve the routing codes.

a. Analysis of Use. When routings appear on traffic, it is first necessary to determine what they represent in terms of origin and destination. This is done by observation. If necessary a tabulation can be made against call signs which will readily reveal which routing is the originator and which the addressee. The difference where present between information and action addressees may be a little more difficult, but checks, for example against priorities, should assist. Further observation will indicate the manner of handling local and relay traffic and the nature of the routings in these instances. Any peculiar use of routings, as in the readdressing of traffic, can also be determined. Following these routings against the net diagram is often helpful.

REF ID: A584682

b. Solution of Routing Codes. The initial step in the solution of routing codes is to check the code groups for characteristics in composition and range. Once these patterns, if present, have been recovered, the next step is the specific identification of code and syllabary groups. Identifications are chiefly based on cribs from known systems to unknown, on net diagrams, on breaches of security, on decode and order of battle material, and on a number of variations of these. As identifications are produced, it may be possible to ascertain the structure of the code and syllabary, such as alphabetical, geographic, order of battle, etc., and this, in turn, assists in future recoveries. In order to suggest methods of attacking this problem, some of the possibilities are discussed below:

(1) *Tying the code group to a known radio station.* Where the station locations are known, several methods present themselves according to the use of the routing codes. The predominant originator out of a station may ordinarily be assumed to be located there. This also applies to the predominant destination, unless destinations are dropped on local traffic. But, because the identification is made with a location, this identification is a true one only if the routing numbers represent locations. If they represent units, then it is necessary to seek further, and the recovery of the location can only be considered tentative in lieu of something more exact. Along with the use of this technique, the lapse between file and intercept times should be averaged for each originator. Messages originating locally will show a shorter time lapse than those previously relayed. If destinations are habitually dropped on the last, or local, leg of a relay, they may be related to the receiving station. For instance, a message from A to C carries the routing "123–567" on the A–B link (fig. 33), but when B relays to C, it only carries "123", thus matching 567 with C.

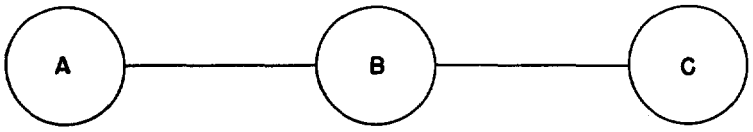

Figure 33.

When the same message is sent to several locations, the local copies may not carry routings while the relayed ones do, making possible the identification of the origin with the sending station. For example, in figure 34, A sends the same message to C and D. The message to C on the A–B channel is marked "123–567", that to D has no routings, thus identifying 123 with A.

(2) *Cribs.* The availability of cribs is chiefly based on the existence of several different routing systems. This may involve checking into networks other than military, such as Naval or domestic, for

REF ID: A684682

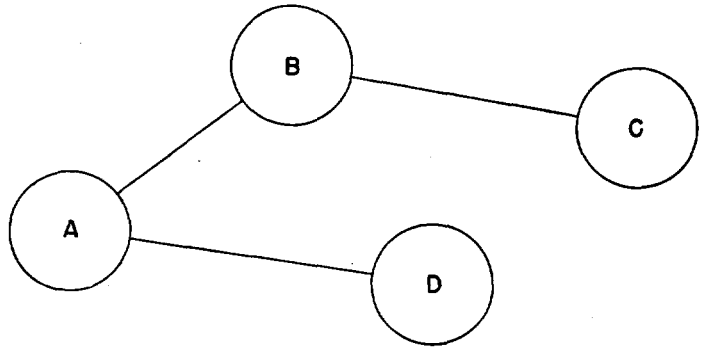

Figure 34.

such data. No possibility should be overlooked. Some of the crib techniques follow.

(*a*) *Relay crib.* If it is necessary for a message to pass over different nets with different routing systems, origins, and destinations can be correlated, and if one system is known, the other can be identified. For example, the message on Net I carries "123–567", on Net II "ABC–JKL", then 123 equals ABC and 567, JKL. One caution here relates to the destination. If this is a book message going to several addressees, there may be a direct correspondence between the originators, but not the destinations, since 567 may be one receiver and JKL another. Sometimes, this can be verified by checking the address and serial numbers.

(*b*) *Book message crib.* Where the same message goes to a number of destinations over different nets employing different routing codes, it is possible to crib originators. This often happens with large centers who work in several nets and may use several routing codes. It also occurs where traffic is relayed out of the net. Naturally, this would also yield a relay crib, but if the first transmission has been missed, the later relay can be used as a book message crib.

(*c*) *Serial number crib.* Serial numbers may be used to crib originators if the serial is a message or signal center number. For example, if a tabulation of serials reveals the following:

Serial	*Routing*	*File date and time*
53	123	092005
54	123	092005
55	123	092005
58	ABC	092005
59	123	092005
60	123	092015
65	ABC	092020
67	ABC	092020

then 123 may be cribbed with ABC.

REF ID:A684682

(*d*) *Error crib.* Where several routing systems are available to a station which works in a number of nets, it may occasionally happen that the wrong system is used. Such errors will generally be corrected yielding a crib between the two codes.

(*e*) *Address and signature cribs.* A unit or person addressed at one routing group in a known system will yield a crib against the same unit addressed at an unknown group. For instance, the 37th Division may be addressed at ABC, known to be Mannheim, on one message, and to 123 on another on the same day; 123 may then be identified with Mannheim. The possibility of unit movement, however, must be considered, and also that of detachments being addressed. The new recovery should be checked against the pattern, if present, of the routing system. In address systems where solution is only partial, but unenciphered code is available, the same address code groups may be used to crib the routing groups. Address code groups, for example, 1234, 5678, may appear with destination group ABC and also with 135. It is not necessary to know the value of 1234 5678 to crib ABC with 135. These same techniques are applicable to signatures and points of origin.

(3) *Operator chatter.* Operator chatter may give away the identity of a code group through the mention of a place name or a unit.

(4) *Address information.* Where addresses are separate from routing codes, use may be made of the address when readable. A unit, whose location is known from other order of battle sources, may be addressed at an unknown routing group thus identifying this group. Consideration must be given in such an instance to the possibility of the unit having moved. If there is some pattern to the composition of the code, the new value should be checked for fit. The recency of the date of the unit's identification and the trustworthiness of the source should also be noted.

(5) *Solved message information.* Solved messages may contain outright assignments of routing code values; more usual, however, is the traffic which permits correlation of internal originators, addressees, or subject matter with externals. All solved messages should be read for clues to routing code identities.

(6) *Miscellaneous sources.* These involve prisoner-of-war reports, captured documents, and similar materials.

(7) *Syllabary solution.* The syllabary to the routing code may be solved by using any of the above methods, but also available is the use of word patterns. If, for example, the routings consist of place names, a list may be constructed of all likely places which will show patterns of repeated or doubled letters, digraphs, etc., within each location, and this may be applied against similar patterns in the encipherments.

REF ID: A5384682

(8) *System change.* If the routing system changes, the continuity techniques discussed in paragraph 44 *b* (2) may be applied. For example, the continuation of a series of serial numbers may serve to identify a new routing designation with an old. Also of value are the contact patterns or associations in which a routing designation may be involved. If, for instance, routing number 123 sends traffic daily to three particular locations, and after the change of system, ABC is discovered following the same pattern, then 123 and ABC may be equated.

c. The above listing of methods of identification is only partial and specific application is dependent on the nature of the communication system under study and on the structure of the routing codes. Identifications, as made, should be evaluated and some sort of validity indicator attached to them as a guide to the reliability of the value. These validities are the result of personal judgment and the peculiarities of evidence and no rules can be laid down for their use on a general basis though in any specific problem definite standards can be set up. Where identifications are based on a crib, however, it should be remembered that the validity of the cribbed value can be no higher than that of the base value.

51. Analysis of Textual Features

The analysis of cryptographic features is concerned with the recognition, use, and distribution of systems, the use of indicators, and the identification of practice and dummy traffic.

a. Recognition. The recognition of cryptographic systems is the first step in their analysis either for traffic analysis or cryptanalytic purposes. Where a discriminant in the clear is present, this becomes a simple matter; encipherment somewhat complicates the problem. But, if there is no discriminant, it is necessary to make use of other features. In the attack, traffic should be sorted down by net and then studied for individual peculiarities. For instance, the following differences may appear as to the type of text:

Net	Type of text	No. of messages
I	4-letter	65
	4-digit	40
	3-digit	29
II	4-letter	48
	5-digit	73
	4-digit	51

Since the net usually represents an order of battle entity it also often represents a crypto-entity. Therefore, all 4-letter traffic passing on Net I (barring the discovery of any further distinction) may be assumed to belong and may be considered for the moment a hemo-

REF ID:A58489

geneous system in itself. Further study is then necessary on the relationships of the two possible systems. Some elemental difference as to form may be apparent which will distinguish them as separate systems, such as the presence of a digit indicator in one. On the other hand, no distinction may be noted and it will be up to the cryptanalyst to determine if the same or different systems are involved. Routings should also be checked in this respect, a relationship between routings (as to echelon, for example) evidencing the likelihood of the same system though passed on different nets. Other factors, beside type of text, are of course also valuable. These include priorities, characteristic serial number ranges, or features of the text such as the nature of the indicators.

c. Analysis of Use. Tabulations of the nets and routings of traffic will often indicate the use of a system. A system, for example, passing only over a water transport net may be identified tentatively as a water transport system, or one used only between intelligence units may be considered a special intelligence system. Caution should always be exercised in making such assumptions because of the ever present possibility that the transmitting of certain traffic over specific nets may result from communications necessity. Peculiarities as to priorities, serial number ranges, and miscellaneous preamble classifications may also assist.

d. Analysis of Distribution. Directly related to the study of use is the analysis of distribution which can be accomplished on the basis of the same tabulation. For instance, a given system may be identified as Air Force and, furthermore, it may be discovered that its distribution is limited to a certain type of Air unit. The tabulation may be as follows:

Net	*Routings*	*Volumes*	*Other characteristics*
I	A–B	354	All traffic uses 5-digit message center numbers.
	A–D	251	
	B–A	240	
	B–D	223	
	C–A	112	
II	A–E	232	5-digit message center numbers.
	A–F	227	
	E–F	116	
	F–E	34	
III	A–G	249	5-digit message center numbers.
	B–G	245	
	G–C	121	
	G–H	112	
	H–G	78	

REF ID: A5384682

Nets I, II, and III are known to be high-echelon Air Force administrative nets. The system under study appears only on these nets and a further check reveals that it composes the bulk of the traffic passed, indicating that it is probably the high-echelon administrative Air system. The 5-digit message center numbers are of interest because numbers of this size appear only on traffic of Air division or higher. Furthermore, most of the routings involved are known to be locations of Air divisions and higher headquarters. Thus, the limits of the distribution of the system are established and now the reasoning may be reversed: any routing appearing with this system may be assumed to be an Air division or above. One-time pads lend themselves to this type of analysis because of their highly restricted distribution. Tabulation of the pad numbers against other features will generally define the users, and since these pads are usually used in only one direction, fix the originator and the one or more recipients.

e. Analysis of Indicators. Where indicators appear in the clear they may be of traffic analysis value. Observation will reveal any peculiarities of the indicators and, if present, they can be correlated with other features.

f. Analysis of Practice Traffic. Practice traffic can often be identified through a study of the text. Messages may be made up at random which generally leads to a patterning and repetition of combinations of letters or digits. Also since there is usually no desire to disguise practice traffic, it may carry a designation in the heading. On the other hand, skillfully designed practice traffic, particularly if an effort is made to conceal it, may be undetectable except for security breaches in operator chatter.

g. Analysis of Control Traffic. Control traffic, if properly handled, may prove very difficult to identify. The usual means of analysis, such as operator chatter, distinctive serial number ranges, etc., are always open. For example, very fast receipting for traffic and few services may indicate that the operators know that the traffic is dummy and are not particularly concerned about it. On the other hand, in an efficient control operation, the operators will not know that they are dealing with dummy traffic and hence will furnish no clues. Another method open to the analyst, however, is the study of traffic volumes and proportions. A level traffic volume on a number of circuits may indicate an attempt to conceal the natural peaks and troughs of a military operation. Moreover, high volumes in areas which other intelligence sources reveal as inactive should be viewed with suspicion. Abnormal rises of certain types of priorities of traffic should be carefully checked for evidences of spuriousness. Control operations carefully planned will take into account the

REF ID:A584489

proper proportions between the various types, but, because of their complexity, breaches of security will often occur.

52. Miscellaneous Items

Every communication system has its own peculiarities in its procedure and traffic. No rules can be given for their analysis except to observe the manner of use and to seek out the relationships between them and other features. It is hoped that the foregoing discussion of certain specific components will not only serve to set the pattern for research on these miscellaneous items, but, more than that, will encourage the traffic analyst to use his ingenuity in the development of new techniques.

Section III. NET RECONSTRUCTION

53. Introduction

The reconstruction of the radio net proceeds simultaneously with the analysis of radio operations. (Furthermore, it is a continuing task since net formations and operating data are seldom static factors.) As noted before, it involves the grouping of stations into nets, the building of the net structure, and the identification of the stations with geographic locations and military units. The resulting net diagram may be drawn in either a schematic or geographic design, according to purpose, and signal features added. This involves, in effect, the reproduction of the radio communications section of the enemy "Signal Operation Instructions" (SOI). These instructions are the orders issued setting up the required signal nets for each military operation and include the assignment of frequencies, call signs, schedules, and miscellaneous data. For a more complete description of the "Signal Operation Instructions," and for United States Army examples of same, see chapter 4, FM 24–16.

54. Grouping of Stations

a. The initial step in analysis is to list all stations and their correspondents. This will yield a rudimentary grouping. For example, the study of a day's chatter reveals—

ABC works DEF
ABC works GHI
ABC works JKL
DEF works MNO
DEF works PQR
MNO works PQR
XYZ works STU
XYZ works ?

REF ID: A384682

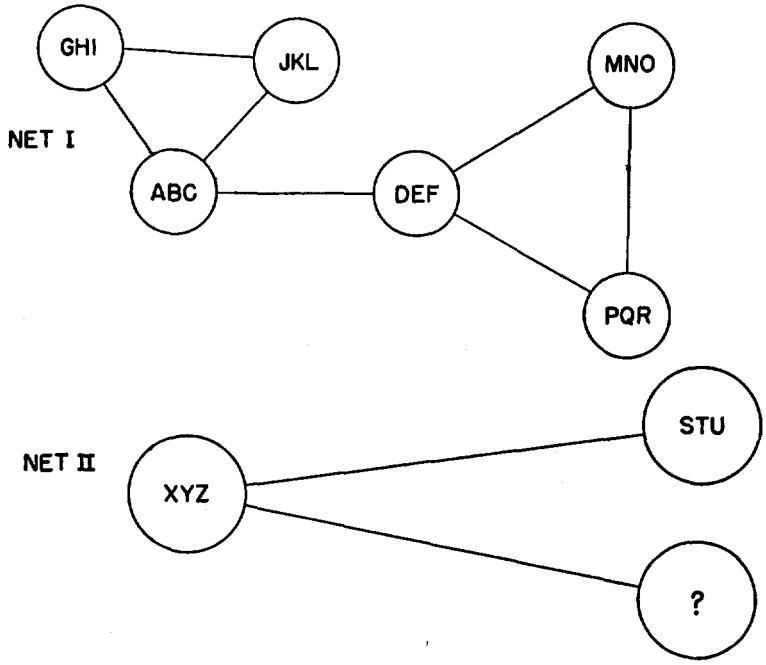

Figure 35.

Thus there are, for the moment, two separate groupings of stations with Net I apparently divided into two groups (fig. 35). It should be remembered that one day's intercept will rarely result in anything as complete as this, and that where daily changing calls are employed, the continuity techniques covered in paragraph 44 must be used. Missed calls present a similar problem. The next task is to study the characteristics of these stations as far as radio operation and procedure is concerned in order to refine the above groupings. It may be found, for example, on the one hand, that the ABC group and Net II exhibit such like characteristics that they appear to belong to the same net and that the connecting link between them has not yet been monitored; and, on the other hand, that the DEF group displays such different characteristics that it must be considered separate and that the DEF call must serve two groups (DEF–MNO–PQR and DEF–ABC).

b. The characteristics to be compared relate to all the features of radio operations:

(1) *Frequencies:*
(*a*) System of use.
(*b*) System of allocation.
(2) *Call signs:*
(*a*) System of use.
(*b*) System of allocation.

REF ID: A584682

(3) *Schedules:*
(4) *Procedure:*
(*a*) Call up.
(*b*) Order of traffic.

(c) Message externals (form and composition of preamble and postamble).

(*d*) Receipting.
(*e*) Corrections and services.
(*f*) Signing off.
(5) *Cryptographic systems.*

c. These items may be used as a check list. Stations, or circuits, do not have to agree in every particular to be grouped, but they should on the major features and, often, on the more characteristic of the minor. What constitutes this latter depends on the net itself. If, for example, strict instructions are issued by the net relative to the order of the preamble components, any deviation, however slight, may be taken as evidence of a separate net. On the other hand, if instructions are rather lax, deviations may not hold any significance. The traffic analyst seldom knows about the nature of the orders on operating procedure, but he can, through careful observance of the net, gain a general impression of how closely it is controlled and how well it is disciplined.

d. The following example illustrates the use of these techniques:

ABC works DEF
ABC works GHI
ABC works ?
XYZ works MNO
XYZ works PQR
STU works ?
? works ?

(1) *The diagrams* (see fig. 36).

(2) *The characteristics:*

(*a*) *Frequencies:*

Net I: Complex-sending Frequency Fixed.
Net II: Star Frequency Fixed.
Net III: Complex-sending Frequency Fixed.
Net IV: Complex-sending Frequency Fixed.

(*b*) *Call signs:*

Net I: Double-station Calls Monthly Changing.
Net II: Double-station Calls Monthly Changing.
Net III: Double-station Calls Daily Changing.
Net IV: Double-station Calls Monthly Changing.

REF ID:A584482

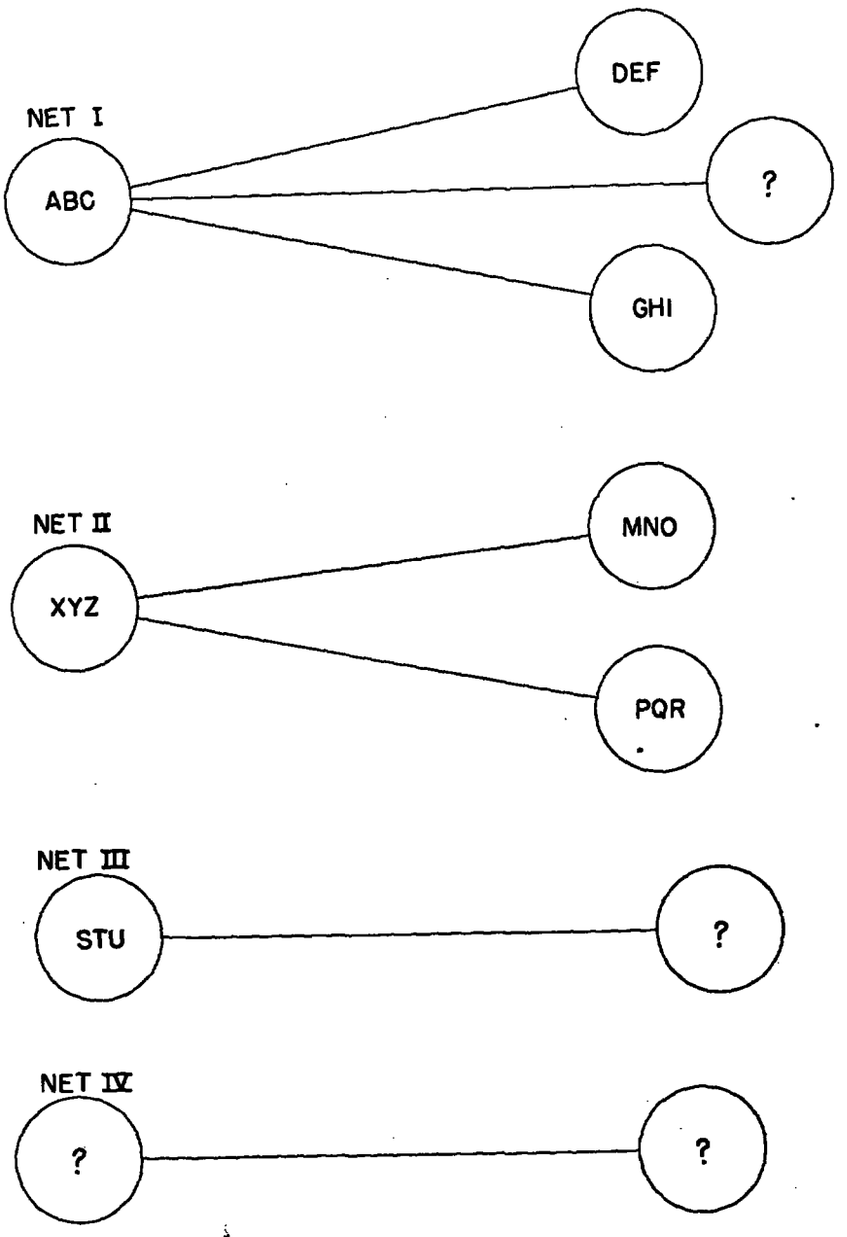

Figure 36.

REF ID:A58489

(*c*) *Schedules:*

Net I: Period.
Net II: Period.
Net III: Unrestricted.
Net IV: Period.

(*d*) *Procedure:*

All Nets: Q signals; International.

1. Call up:

All Nets: Usual.

2. Order of traffic:

All Nets: Precedence traffic first.

3. Message externals:

Net I:
Preamble: Circuit No.; Precedence; Message Center No.; Group Count; File Date and Time; Routings.

Net II:
Preamble: Circuit No.; Message Center No.; Group Count; File Date and Time; Routings.

Net III:
Preamble: In-desk No.; Precedence; Message Center No.; Group Count; File Date and Time; Routings.

Net IV:
Preamble: Circuit No.; Precedence; Message Center No.; Group Count; File Date and Time; Routings.

Separators: Same for all nets.

4. Receipting:

All Nets: Usual.

5. Corrections and services:

All Nets: Usual.

6. Signing off:

Net I: Usual.
Net II: Usual.
Net III: Makes next schedule.
Net IV: Usual.

(*e*) *Cryptographic systems:*

Net I: A, B, C, D.
Net II: A, E, F.
Net III: A, G, H, I, J.
Net IV: A, B, D.

e. It will be observed from the above that Nets I and IV have similar characteristics, and that II and III differ in certain important respects. Net II uses a net frequency. This alone would be insuffi-

REQ# 109:AS84819

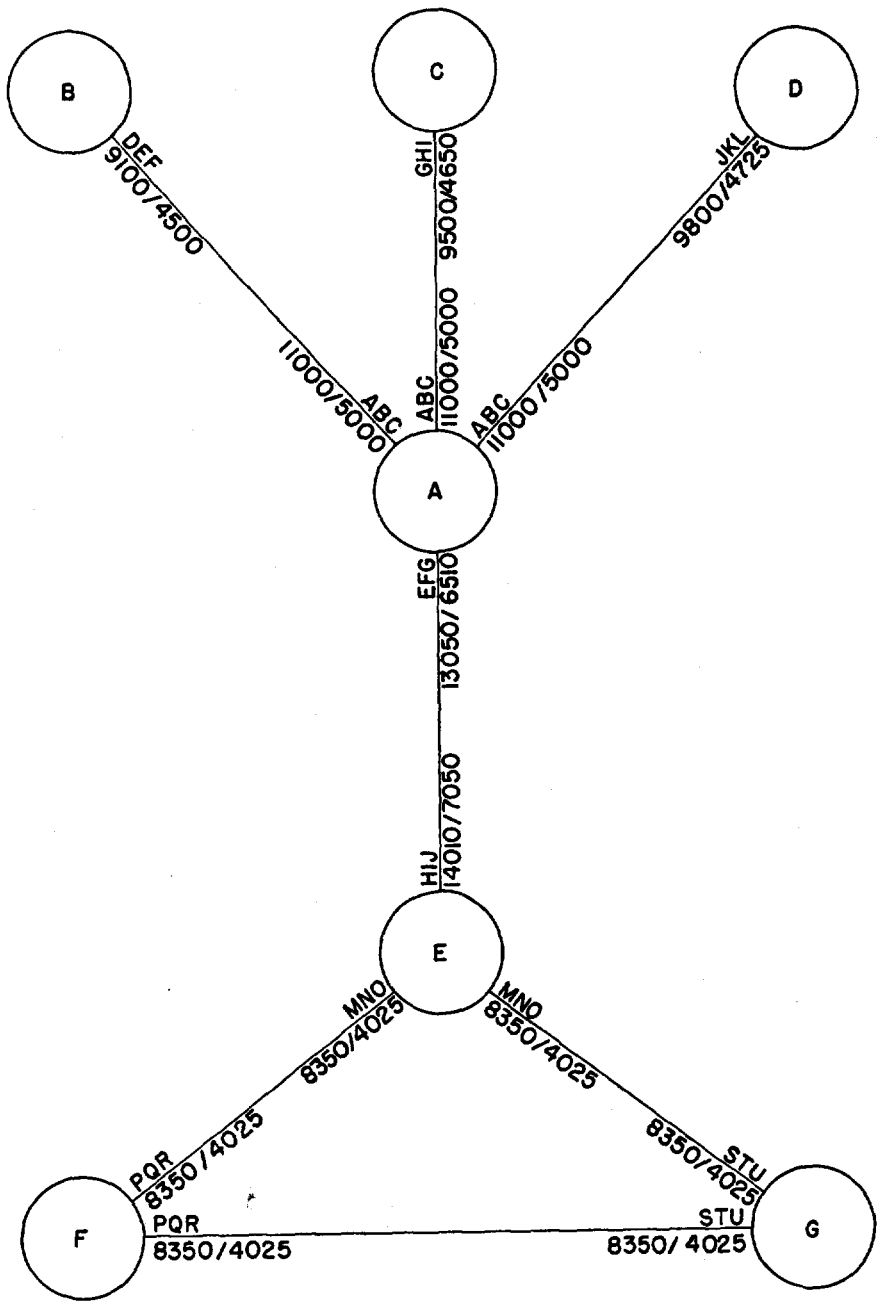

Figure 87.

REF ID: A58489

cient grounds for isolating it, but the position of the precedence in the preamble, and the use of different cryptographic systems furnishes enough additional evidence. Net III employs daily changing calls, usually adequate premise for setting a net apart. In this instance, added weight is given by the use of unrestricted signaling, the in-desk number, and the distinctive cryptographic systems.

55. Building the Net Structure

a. An elementary amount of net building is accomplished in the process of grouping the stations into nets. A number of additional techniques are now brought into play to complete the task. The crux of the problem involves the identification of different frequencies and calls with a station, in other words, that call ABC is at the same station as DEF, or that 11,000 kcs is at the same station as 9,050 kcs. When this has been done, the links and groups will fall into place and the net reconstruction be completed. It is difficult to set down definite methods to be pursued because much depends on the individual characteristics of the network. The following paragraphs discuss some of the principles involved and are suggestive of the general approach. Examples used are based on the diagram in figure 37.

b. Frequencies, Calls, Schedules. As a general rule, like calls or like frequencies may be assumed to be at the same station. Thus, in figure 37, the call ABC on frequencies 11000/5000 kcs was always considered the same regardless of station called. But caution should be exercised in arriving at this decision because it is always possible that no relationship may exist. A check of schedules is helpful. If ABC is heard working two different stations at the same time, it is likely that the two ABC's are separate stations. Other checks are traffic routings, cryptographic systems, etc.

c. Interlocking Serials. Where a radio station in-desk number is used, the serials out of different calls can be interlocked. When the serial is a message or signal center number, the interlocking technique may also be used, but account must be taken of the relay possibility. For instance, in figure 38 A and C are under analysis in an attempt to tie them together. Message center numbers on traffic out of ABC run:

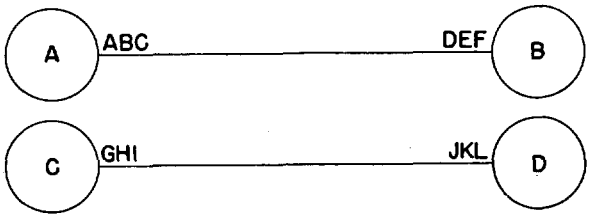

Figure 38.

RHQR 109:AD684682

1578	1607
1579	1608
1585	1609
1586	1610
1587	1629
1588	1630
1589	1631
1603	1641
1605	1642
1606	1643

Message center numbers on traffic out of GHI run:

1581
1582
1583
1584

But, if the latter traffic shows evidence of being relayed and, if there are no other grounds for identification, a conclusion cannot be reached. On the other hand, if it is found that nonrelay traffic on this net carries no routings, but that relay traffic does, and that all the messages listed above under both ABC and GHI have no routings, it may be assumed that ABC and GHI are co-located. Other types of serials, such as link numbers, generally cannot be used for this purpose.

d. Traffic Routings. On the theory that the predominant originator out of a call or frequency and the predominant destination into a call or frequency represent the location of the call or frequency, a tabulation of traffic routings may be used for net-building. For example, tabulations of routings relative to ABC and GHI reveal:

Call	*Routing*	*Volume*
Out of ABC	1234	75
	2345	43
	3456	10
	4567	3
Into ABC	1234	58
	2345	12
	4567	1
Out of GHI	1234	158
	2345	79
Into GHI	1234	101
	2345	39

The similarities in routings suggest their co-location though further proof is necessary for positive identification.

(1) Also useful is the system of omitting routings on local traffic. Calls of the same station will demonstrate similar relay routing lists

REF ID:A584482

with the station's own routing rather low in the tabulation. Book messages can be used as explained in paragraph 50*b* (2) (*b*).

(2) A somewhat different use of routings is in the inferring of links which have not been heard. For example, the routing 1234–6789 is noted on a message from A to B. 1234 has been located at C, but no link from C to A has been observed. Nevertheless, there must be some connection either through another station or directly. It is difficult to determine which is the case; a check of file time against intercept time will sometimes serve to indicate whether, considering the precedence of the message and the usual time lapses on the net, how many prior relays are likely. A tentative diagram could be drawn as shown in figure 39.

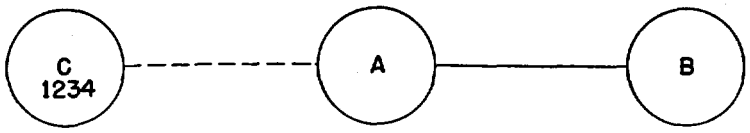

Figure 39.

e. Cryptographic Systems. On locally originated traffic, distinctive cryptographic systems, such as one-time pads, may be used to tie calls or frequencies together. As in the application of all message center features to radio stations, care must be taken to avoid relayed traffic.

f. Chatter. Items of chatter furnish important clues to net-building. In many instances, outright statements are made which relate one link to another. For example, ABC tells DEF, "At 1100 I have schedule with GHI." At 1100, JKL is heard calling GHI, indicating the identity of JKL and ABC. Mention of operators names or other local personalities also assist by the appearance of the same personality on different links.

g. Relayed Traffic. The study of relayed traffic presents one of the most important techniques in net-building. As messages pass from station to station, the net automatically reconstructs itself since it is only necessary to trace the messages' path to determine the structure. The chief caution to be observed is the possibility of having missed a relay, but this can generally be checked by differencing the intercept times. For example, a message is transmitted from ABC to DEF and an hour later from GHI to JKL. The diagram in figure 40 may then be drawn.

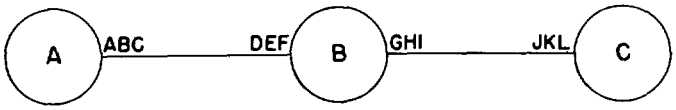

Figure 40.

REF ID:A684682

The possibility of the picture being as shown in figure 41, however,

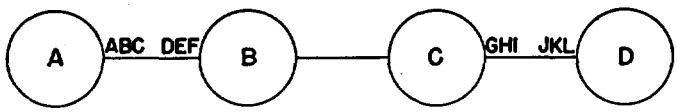

Figure 41.

does exist, but the short time lapse of one hour makes it unlikely that the extra relay took place. Of course, what constitutes a short time lapse is dependent on the habitual lapses and on the precedence of the messages under study.

h. COLLATERAL INFORMATION. Direction-finding is an important technique and, when the radio system is highly secure, may furnish the chief method of net building. Decode material, captured documents, prisoner-of-war reports, when available, should also be used to the fullest extent.

56. Location of Stations

The geographic location of stations is the third step to be performed in the reconstruction of the radio system.

a. IDENTIFICATION WITH A KNOWN ELEMENT. Identification with a known element is one of the chief means of locating the station. For instance, the tying-in of a station to an identified routing number will place the station. Similarly, calls, frequencies, serial ranges, and cryptographic systems which have been matched to locations may serve this purpose. The techniques involved can be derived from those discussed in this section and in section II. A validity should be attached to each station identification dependent on the weight of the identifying evidence.

b. CHATTER. Chatter often furnishes identifications through operator carelessness. Clues to locations, such as mentions of weather, local conditions, and similar items, should be carefully appraised.

c. DIRECTION-FINDING. Direction-finding is here listed separately because of its importance in the locating of stations. Often it is the only means available. This is particularly true in low-echelon nets where movement is liable to be frequent and where message externals are held to a minimum. It may sometimes be necessary to utilize a knowledge of order of battle, geography, and military strategy in connection with direction-finding. Bearings will usually give a general area, larger or smaller according to the distance from the target and the accuracy of the bearings, but seldom will pin-point a location. However, inference as to the most likely location within narrow limits is permissible provided it is backed with sound reasoning.

d. COLLATERAL MATERIAL. Order of battle information, decode

REF ID:A58489

material, captured documents, and similar items are often of great value in placing stations. For example, a division headquarters, whose radio station has been identified, moves to a new location. This new location is revealed by other sources. It may then be assumed that the headquarters radio station is also at this point.

57. Unit Identifications

a. The last step in the reconstruction of the radio system is the imposition of the order of battle. The order of battle underlies the entire net organization and each radio station must be identified with the units which it serves. In the high echelons, the nets are usually composed of large fixed installations which serve a number of units in the vicinity. Generally, however, there will be one major unit which the station represents. In the lower echelons, on the other hand, there will be a close correlation between unit and station. This is partially the result of the customary policy of manning large installations with an independent signal organization, while in the lower echelons the signal sections operate as an integral part of the unit.

b. The techniques of matching units with stations are only outlined below since it is felt that the preceding discussion sets the pattern of reasoning.

(1) *Identification with a known element.* This involves such items as call sign or frequency patterns which may be distinctive for certain commands or echelons, serial number ranges, routing systems, cryptographic systems, and procedural characteristics.

(2) *Chatter.*

(3) *Order of battle.* Beside the usual method of identifying a unit with a location and a location with a station, it is sometimes possible to force identification. For example, the order of battle information given in figure 42 is known, and a net is reconstructed as illustrated in figure 43.

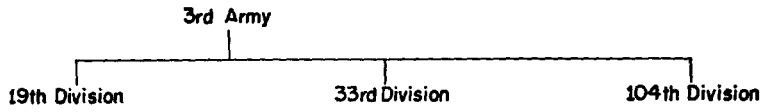

Figure 42.

It becomes apparent that station D is probably the 104th Division. In many cases, the echelon of command can be determined from the structure of the network and this may later lead to the identification with specific units. For example, the network shown in figure 44 is built.

REF ID: A384682

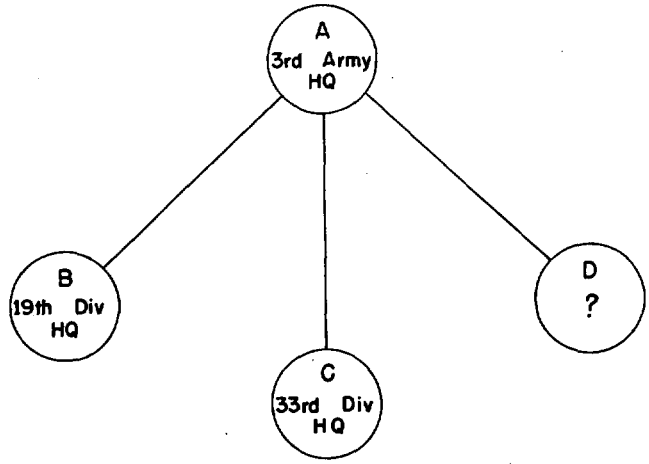

Figure 43.

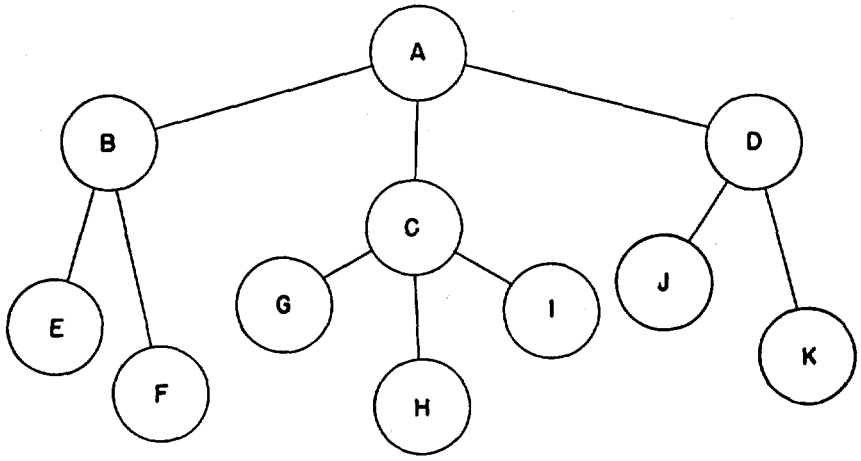

Figure 44.

It will be observed that A is probably the top headquarters, that B, C, and D are lower equivalent units, and that their out-stations are still further down the line. If anything is known of the order of battle in this area, it may be possible to match it with the net diagram.

(4) *Collateral material.*

58. Dummy Nets

Dummy nets and stations may be set up for the same purpose as that served by control traffic. Often when a headquarters is moved, a radio station is left operating at the former location to conceal the redeployment. Similarly, when it is desired to misdirect the

REF ID:A58489

enemy's attention, entire spurious nets may be employed to create the appearance of activity in an inactive area. The detection of such nets and stations may be difficult to accomplish and is largely dependent on the ability to uncover breaches of security resulting from careless chatter or ineptitude.

59. The Integrated Diagram

The immediate objective of the reconstruction of the nets is the production of the integrated network diagram which will serve as a

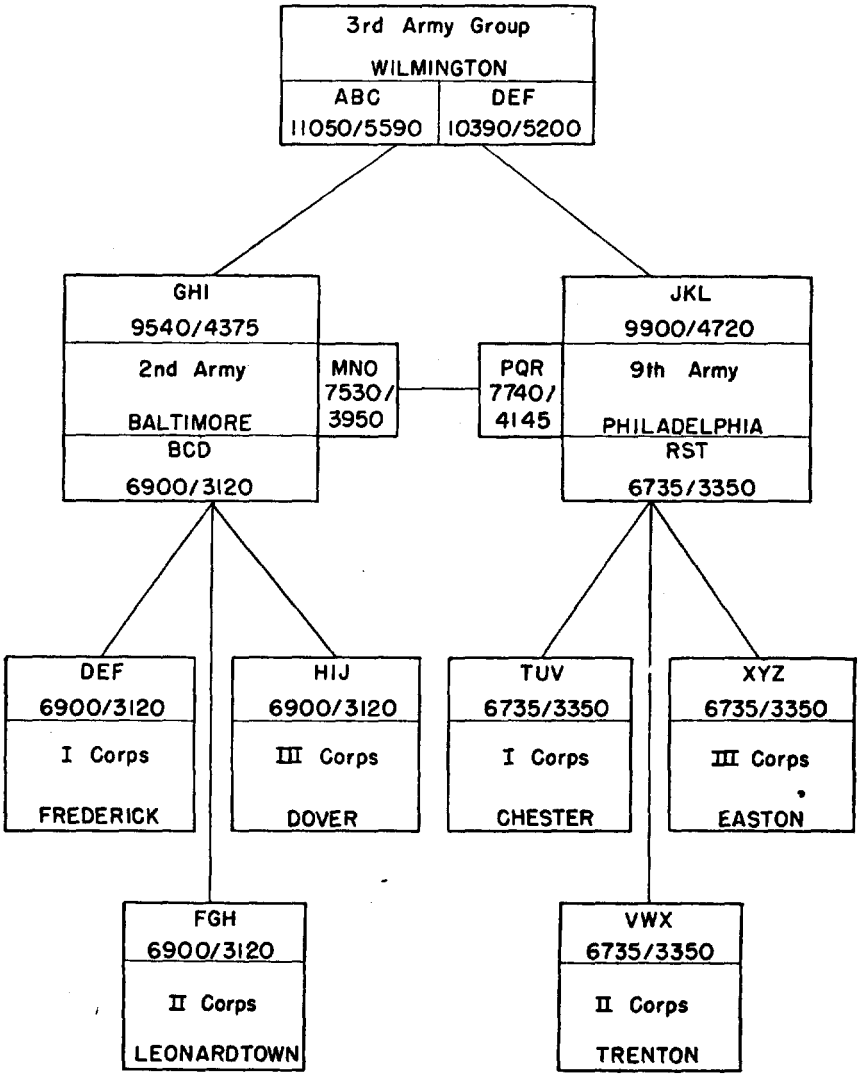

Figure 45.

REF ID: A5384682

backdrop for future study of the nets and for the production of intelligence and cryptanalytic aids. Because of the limitations of space and the complexities of some of the data, however, it is often not possible to include all the information necessary to a complete network picture in diagrammatic form. Therefore, certain basic diagrams may be produced either in schematic or geographic arrangement, and the omitted data supplied in accompanying charts. An example of such a basic diagram is given in figure 45. It will be noted that it contains order of battle units, locations, frequencies, and call signs, and is drawn schematically. Other data, which could be appended in chart form, might include range of serial numbers at each location or on each link, cryptographic systems used, and routings which appear or are identified with units or locations.

Section IV. METHODOLOGY OF ANALYSIS

60. Introduction

The preceding sections of this chapter dealt with the techniques of traffic analysis in regard to the study of radio operations and the reconstruction of the nets. In order to perform this analysis and achieve these ends, the proper machinery for processing raw material must be employed. This section is concerned with this machinery, and includes the processing of the chatter logs and the maintenance of appropriate files. The methods and forms outlined are only suggestive of the possibilities and changes should be made as necessary to meet individual situations.

61. Intercept Operator's Log

a. The raw material of traffic analysis is the chatter log. This is a complete record of the transmission as it is copied by the intercept operator and includes both traffic and chatter. An example of a portion of such a log follows (procedure is Q signals and international):

ABC	(2765 kcs) VVVVVVVVVV	
	DEF DEF DEF de ABC ABC ABC VVV QSV K	2133Z
DEF	(3152 kcs) VVVVVVVVVV	
	VVVVVVVVVVV ABC ABC ABC de DEF DEF	
	DEF VVVVV K	2135Z
ABC	V's QSA ? QSA ? K	2138Z
DEF	QSA4 QSA4 QSA? K	2139Z
ABC	QSA4 QTC 2 OP	
	QTC2 OP K	2140Z
DEF	QRV QRV K	2141Z

REF ID:A58489

ABC	QTC QTC	
	NR695 OP GR14 121541 BT	
	1904 2391 6025 8034 1709

	4114 EEEEEEEEE 4104 5281 7399	2144Z
DEF	3? 3?	
ABC	7399 1211 BT QSL? QSL? K	2145Z
DEF	R	2145Z
ABC	AS5 AS5 K	2146Z
DEF	OK OK OK	
	SAW TOM IN TOWN LAST NITE	2148Z
ABC	WHERE WAS HE GNG?	2149Z
DEF	31 Div They lost 2 ops in raid	2151Z
ABC	TOO BD AS AS	2151Z
ABC	QTC QTC QRV? K	2155Z
DEF	QRV QRV QRV K	2156Z

b. The important items of this chatter log must be extracted and recorded. The usual method to accomplish this is the use of the intercept operator's log on which is entered the significant features of the transmission as they occur. A sample log based on the above chatter is shown in figure 46.

c. The log is the basic analysis recording. Once it has been completed it should not be necessary, except in rare instances, to go back to the chatter logs. Consequently, considerable care should go into its preparation. It should contain all the data required for analysis and for the compilation of files.

62. Files

The contents of files are largely determined by the particular problem. It will generally be found advantageous, however, to maintain files based on the following:

a. Frequency. A master-frequency file containing a record of all frequencies, the time and date when first heard, associated frequencies, location, calls if reasonably fixed, net, etc.

b. Call Signs. A master call-sign file containing a record of all calls, date when first heard, associated calls, location, frequencies, net, etc. The information on the card here or in the frequency file may be kept to a minimum if one is adequately cross-indexed to the other.

c. Serial Numbers. Where practicable, files should be maintained on the various serial number ranges together with related features.

d. Routing System. A file of routing code groups with proofs of identifications.

e. Cryptographic Systems. A file of all cryptographic systems, how they can be identified, by whom used, for what purpose, and net.

REF ID: A584682

Date_____

GMT	Freq.	C/S	No.	Serial	Origin	Dest.	Remarks
2133	3152	ABC					V's DEF de ABC
2135	2765	DEF					V's ABC de DEF
2138		ABC					QSA?
2139		DEF					QSA4
2140		ABC					QSA4
2144		ABC	695				OP GR14 121541 1904 . . . . 7399 1211

2149		ABC					WHERE WAS HE GNG?
2151		DEF					31 DIV. THEY LOST 2 OPs IN RAID

Figure 46. Sample intercept operator's log.

In the case of distinctive features, such as one-time pads, files should also be maintained for each pad together with other pertinent data.

f. PROCEDURE. A file on the meanings of noninternational procedure signs and signals.

g. PERSONALITIES. All personalities appearing in traffic or chatter together with the connection in which they were mentioned. Personalities derived from other sources can be added to this file but they should be so marked.

h. ORDER OF BATTLE. All order of battle identifications originating with traffic analysis plus that available from other sources.

i. NET, GROUP, AND LINK. A running record should be kept on each net or, where necessary, group or link which will act as a history and also include the basic data for station identifications as to location and order of battle.

REF ID:A58489

j. Collateral Materials. Appropriate files should be maintained for all collateral materials. In the case of direction-finding, information must be organized to suit the particular problem. Files, as required, should also be maintained on solved messages, captured documents, and similar items.

REF ID: A5384682

CHAPTER 4

APPLICATIONS OF TRAFFIC ANALYSIS

Section I. INTERCEPT OPERATIONS

63. Introduction

Traffic analysis plays an important role in the direction of intercept. It furnishes the basic information necessary to the intercept station for the performance of its mission; its requirements are coordinated with those of intelligence and cryptanalysis for the purpose of prescribing cover and fixing priorities; and it checks certain phases of station performance. Depending on the nature of the organization, traffic analysis may also be responsible for the specific determination of missions for the intercept stations.

64. Intercept Information

a. The elementary function of traffic analysis in intercept control is the providing of basic net data to the stations. This includes chiefly frequencies, calls, schedules, and station locations. Other information may be added as required. A sample listing follows:

Locations	*Frequencies*	*Call signs*	*Schedules*
Hoboken	10500/5030	ABC	0100; 0300;
Zanesville	11350/6125	DEF	0500; 0700;
			1700; 2100
Hoboken	10500/5030	ABC	even hours
Overton	16400/7625	GHI	
Overton	16400/7625	GHI	0900; 1100;
Zanesville	11350/6125	DEF	1300; 1900; 2300
Star Lake	8430/4175	MNO	0700; 0900;
Ticonderoga	8600/4235	PQR	1800; 2200;
Star Lake	8430/4175	MNO	0400; 0600;
Buffalo	7550/3965	STU	1900

b. Technical reports may also be furnished to the intercept station. Certain items are fundamental. For instance, in the case of a changing-call system, the elements of the system are necessary for con-

REF ID:A58489

tinuity in cover; the same is true of frequency systems, procedure signs and signals, etc. In the determination of the type of materials to be forwarded, a balance must be struck between the requirements of security and those of intercept. All information is of use to the station, but some is more essential. Thus, it should be the policy to furnish everything that is available, consonant with security. Even much data which appear irrelevant may be of value if only to indicate to the intercept station the importance placed upon its product.

65. Types of Coverage

If it were possible to cover all desired nets or links twenty-four hours a day, there would be few problems to intercept control. Because of limited facilities and operators, however, such is not the case, and it becomes necessary to draw a number of fine distinctions with regard to types of cover and the order of priorities. Thus, cover may be divided into several types according to the purpose it serves.

a. FULL TIME. This is the highest of all intercept priorities (except in special instances) and consists of complete daily monitoring of each assigned net or link on all known schedules. The number of missions included in the full time classification should be sufficiently small to permit the monitoring station to cover all of them with ease so that, unless something entirely unforeseen intervenes, intercept is assured. Full time cover should never tax the maximum facilities and personnel of the station except under unusual circumstances, since positions should be reversed for other types of cover. These positions may, of course, be switched to full time if absolutely necessary.

b. SAMPLING. Nets or links which cannot be covered on full time may be put on sampling. The net is checked at regular intervals, the intercept station listening to several missions each day and rotating them until all have been monitored when the list repeats. This method yields some traffic on a variety of nets and enables the traffic analyst to keep abreast of current developments.

c. SEARCH. This mission consists of a search through a frequency band or bands for new transmitters and for changes of wave lengths. In the early stages of traffic analysis, this mission is of first importance since it serves to outline what is on the air.

d. PRELIMINARY CHECK. New frequencies discovered on search must be followed up to ascertain their genuineness and desirability. To accomplish this, they are placed on preliminary check, actually an extension of the search mission. If proved valuable, these links are then transferred to either full time or sampling.

e. SPECIAL CHECK. Special check is the complete cover of a net or link for a limited period of time. The check may serve a variety of

REF ID: A584682

purposes such as whether the link is still active, or what its schedules are, or whether it can be heard at the monitoring station.

66. Factors in Assignment

The main considerations in the assignment of missions to specific intercept stations are:

a. The ability of the station to hear at the times desired.

b. The availability of positions and personnel for coverage at the station.

c. The most economic use of the station's time. This involves the problem of the common transmitter which makes it desirable to assign an entire net, where possible, to one station. For example, in the net shown in figure 47 both the A–B and A–C link should be assigned

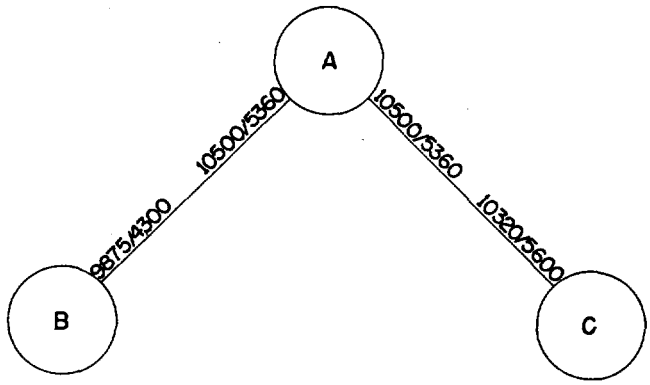

Figure 47.

to the same station, for by covering A throughout the day the activities of the net can be followed. On the other hand, if the intercept unit can hear A and B, but not C, it would become necessary to split the assignment. A second consideration in following this procedure is that the common transmitter arrangements tend to spread out until they include more links than can be handled at a single station. For example, C works another station on 10320/5600, B does likewise on 9875/4300, etc. Thus, a compromise assignment must often be devised.

d. The communication facilities between the station and the central analysis agency. In many instances, it is of prime importance that traffic arrive at a central point for analysis within the shortest possible time. For this reason assignments are sometimes made to the station which, though unable to provide the best cover, can forward the traffic the fastest.

REF ID: A584682

67. Factors in Priorities

The determination of priorities rests on the threefold requirements of intelligence, cryptanalysis, and traffic analysis. The traffic analysis needs are:

a. INTELLIGENCE. Traffic analysis, on its own, contributes to the intelligence picture and consequently is interested in seeing to it that the nets which yield the major portion of traffic analysis intelligence are adequately covered.

b. ANALYSIS OF RADIO OPERATIONS. In the study of certain elements of radio operations, intensive cover may be found valuable for limited periods of time, for example, the defining of schedules on a given net. Special check may be used to this end.

c. NET RECONSTRUCTION. Traffic analysis must maintain an up-to-date picture of all radio nets for the benefit of intercept control personnel regardless of the needs of intelligence and cryptanalysis (because those needs may change from time to time), and information must be available to permit the immediate assumption of coverage. In the reconstruction of nets of little current significance, or where the significance is unknown, special check is useful. Where nets have already been reconstructed and it is merely desired to watch them for changes, sampling cover is satisfactory.

68. Interpretation of Requirements

Besides making its own demands on intercept, traffic analysis frequently interprets the requirements of intelligence and cryptanalysis in terms of links and nets. For example, intelligence expresses interest in a given area; traffic analysis knows what links or nets to monitor in order to blanket the area. Or cryptanalysis wants more traffic in a given system, a certain routine message, or a type of isolog; traffic analysis knows what nets or links carry large portions of this traffic.

69. Station Performance

a. In order to insure proper performance by the intercept station and to check on the fitness of the assignment, coverage results are continually evaluated.

b. If a serial number, relative to the sending station, is available, it may be analyzed for missed traffic. Forms can be devised for the simple maintenance of this data which, in turn, can be obtained from the intercept operator's log. Other features, such as message center serials, may also be employed to check for missed traffic though care must be exercised in making use of them. Incidentally, there is a tendency to place emphasis on the volume of traffic copied at a station as a gauge of its efficiency. This attitude is to be discouraged since

REF ID: A684682

it is often necessary to monitor nets or links which yield little traffic, but do carry cryptographic systems of great cryptanalytic or intelligence value, or possess useful traffic analysis features.

Section II. APPLICATIONS TO CRYPTANALYSIS

70. Introduction

a. The relationship between traffic analysis and cryptanalysis is not easily defined. Often an arbitrary line must be drawn between them when it is desired to keep the functions separate, but it will be found necessary, whatever the distinctions made, for the cryptanalyst to be grounded in traffic analysis and the traffic analyst in cryptanalysis. This arises from the basic concept of traffic analysis and cryptanalysis as closely related processes with traffic analysis furnishing the frame of reference within which cryptanalysis is performed. The material supplied by traffic analysis falls into four main categories:

(1) General background information.
(2) Crib messages.
(3) Isologs.
(4) Chatter.

b. It should be borne in mind by the traffic analyst that the requirements of the cryptanalyst vary according to the stage of solution. At times, for example, an isolog may be of great value, at other times it may be of no use at all, and at still others it may be of potential use pending the development of the problem. Therefore the traffic analyst should gear his production in this field to the needs of cryptanalysis.

71. General Background Information

Traffic analysis furnishes a large amount of routine information relative to communication features which assist the cryptanalyst. Some of the main items are—

a. Routings. The knowledge of the origin and destination of traffic is fundamental.

b. Identification of Systems. Traffic analysis contributes to the identification of cryptographic systems where discriminants do not form an obvious guide and assists in the sorting of traffic into homogeneous groups.

c. Use of Systems. Through discovering the use of systems, and any peculiarities relative to it, traffic analysis aids the cryptanalytic processes. Specific applications, of course, depend on the nature of the system and the externals available.

RECD 10 : 2684682

72. The Crib Message

a. DEFINITION. When it is possible to assume portions of the underlying plain text through the recognition of external characteristics, a message may be termed a crib message. Crib messages may be divided into two main groups.

(1) Messages which display a direct external-internal relationship, as the correlation of an internal signature with the external originator.

(2) Messages which are proforma reports. These arise out of the command function which necessitates the rendering of reports both up and down channel. They are usually formalized to insure completeness and thus present several portions of predictable plain text. Reports are of two types: those periodically filed which are called routines, and those which are forwarded as the situation requires.

b. IDENTIFICATION OF CRIB MESSAGES. (1) *Use of originator or destination.* If traffic contains internal addresses or signatures, they may be assumed by a knowledge of order of battle in relation to the message routings. Thus, messages originating at Dallas, known to be the location of the 14th Division, may contain the "14th Division", its commanding officer, or one of its subordinate units in the signature position. The possibility of several units at a location should not be overlooked.

(2) *Use of serial number range.* The serial number range may be tied to an internal originator, and the signature on all traffic in the series may be predicted.

(3) *Use of other features.* In the study of internal originators and addresses, other features, such as cryptographic system, relationships between preamble originators and destinations, etc., should be correlated with the above. For example, a specific originator may be defined by a combination of routing origin, serial range, and cryptographic system.

(4) *Use of external patterns.* In the case of report messages, these can often be distinguished by the characteristics of the traffic which chiefly include—

(*a*) *Destinations.* Because the report is regularly rendered to specific people, the destinations will furnish one peculiarity of the message. If order of battle is known, the relationship between the originator and the destinations may be explained and it may even be found possible to identify the nature of the report. When the routine pattern has been established, the order of battle must be watched for changes which will result in alterations of the pattern.

Note. Crib messages bear a very direct relationship to the military situation and the order of battle since they are, particularly in the report type, instrument of the command process. Thus, a detailed knowledge of enemy dispositions and movements is essential to the study of crib traffic.

REF ID: A5384682

(*b*) *Cryptographic system.* Reports usually pass in the same system. But, where a change does take place and it can be recognized, the crib may assist in a solution of the new system.

(*c*) *Serial number range.* Because the same unit generally originates the same report, characteristic serial number ranges may be of value.

(*d*) *File date and time.* Reports which are routine in nature often exhibit a periodicity in the file date and time. For example, a ten-day report will be filed every tenth day, or a daily report as of 1700 will usually carry a file time after 1700 of that day.

(*e*) *Message length.* Because of the stereotyped nature of a report, the group count may show some consistency. In many cases, however, the length will be determined by the amount of information to be filled in, so while the message length acts as a guide, lack of regularity in this respect does not rule out the possibility of a genuine crib message existing.

(5) *Use of solved messages.* The reading of messages often produces crib traffic not previously suspected. This traffic should be studied and its characteristics noted to aid in future solution. Furthermore, it may be assumed that, if one unit originates a report, the same report is required of all other similar units. A check with order of battle will reveal the location of these other units and the specific traffic can be studied. For instance, a report may be observed from an oil depot to headquarters. This suggests that other oil depots also originate a similar report. These depots are then located and their traffic examined for the proper external characteristics as indicated on the decode.

73. The Isolog

a. DEFINITION. An isolog exists where the underlying plain text is encrypted in two different systems. There are many types of isologs depending on the nature of the cryptographic system, and it is hardly possible in this text to explore all the likely variations. Isologs arise from the cryptonets which, in turn, bear a close relationship to the order of battle. They are caused in three main ways:

(1) *The relay isolog.* When a message is relayed from one cryptonet to another, an isolog is likely. In figure 48, a message passed from A to C is reenciphered at B who holds both systems I and II. This type of isolog is usually formed by traffic passing up and down channels where reencipherment is necessary into simpler and simpler systems, the more forward the unit.

(2) *The book-message isolog.* Messages which are to be sent to a number of recipients in different cryptonets must be enciphered in different systems. In figure 48, for instance, if B wants to send the same message to A and C, the appropriate system is used for each.

REF ID:A58489

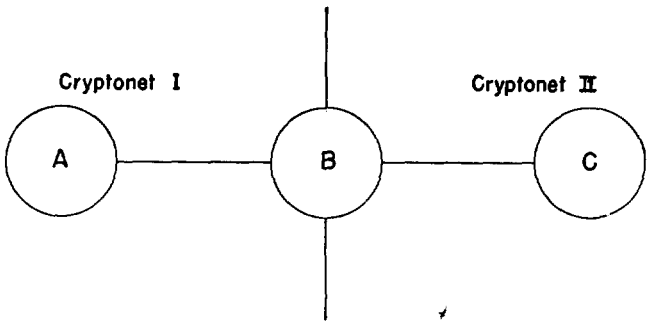

Figure 48.

(3) *Cryptographic error.* At times the code clerk will encipher a message in the wrong system. This will be refused by the receiver and the originator will reencipher in the correct system, yielding an isolog.

b. Identification of Isologs. (1) *Mechanical approach.* Isologs may be found by sorting traffic by originator and then looking for similar group counts and file dates and times. Where the two systems involved are not radically different in makeup, group counts should be close. Likewise, file dates and times, under most circumstances, will be similar.

(2) *Use of cryptonets.* A knowledge of cryptonets often simplifies the search for isologs. Certain locations, because they are in several nets, will be predisposed to the transmitting of this material. For instance, in the group of cryptonets shown in figure 49, the logical

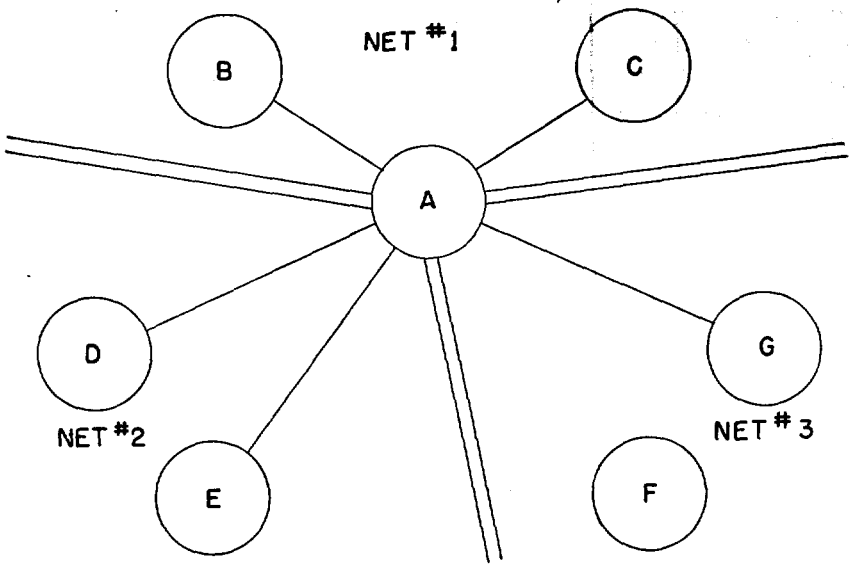

Figure 49.

REF ID:A684682

traffic to study for isologs would be messages received and transmitted by station A. Order of battle changes should be carefully followed for the cryptonets are formed by units, not radio stations, and the movement of a unit often means that a new location must be taken into account.

(3) *Use of refused traffic.* When messages are originally sent in the wrong system they will be refused or serviced, sometimes in the clear. This is a signal to watch for a retransmission of the traffic in its correct version. For this reason alone, it is important for the traffic analyst to be thoroughly familiar with procedure and the methods of servicing both encrypted and plain traffic.

74. Chatter

The study of chatter occasionally produces information of cryptanalytic value. Some of this material may be simply a discussion in the clear of cryptographic features by the radio operators. In other instances, the derivation of information may require some analysis.

Section III. APPLICATIONS TO INTELLIGENCE

75. Introduction

a. It is one of the chief objectives of traffic analysis to produce direct intelligence. Seldom will this be "pure" traffic analysis intelligence, but rather it will represent the fusing of traffic analysis data with material from other sources. In some cases, traffic analysis will furnish the initial indication; in others it will act as confirming evidence. The ability of traffic analysis to contribute to order of battle is based on the necessity for communication between military units and the fact that these communications are expressive of the enemy's dispositions and intentions.

b. The problem breaks down into three parts—

(1) Determination of order of battle relationships.
(2) Determination of movement.
(3) Identification of units.

76. Determination of Order of Battle Relationships

a. NET STRUCTURE. The net structure is one of the chief keys to the study of order of battle relationships. Methods of utilizing this element are covered in paragraph 57.

b. CONTACT RELATIONSHIPS. (1) *Traffic associations.* A study of the traffic contacts of any one point gives some indication of the nature and the echelon of the unit since every message passed implies a relationship between the sender and the recipient. In order to use

REF ID:A58489

this technique, some of the factors must be identified and the general principles of the enemy order of battle known. For example, if the following set of contacts are recorded over a period of time, and B, C, and D are all air transport units, it is likely that A is also—

Location A

To B	43 messages
To C	29 messages
To D	12 messages
From B	38 messages
From C	15 messages
From D	3 messages

Of course, other factors must be considered and these may alter the conclusion. In some orders of battle, for instance, certain of the air transport units may come under the command of an Army unit and A may represent this Hq. Thus, hasty interpretations relative to traffic associations cannot be made, and the use of all available collateral material is necessary. It may be noted, for example, that certain types of traffic associations are characteristic of units at divisional level. These associations may involve heavy traffic with Army Hq., somewhat lighter traffic with Army group, and a little traffic with characteristic points in the homeland. Similar patterns of other locations may indicate the presence of a division. There are so many variations to this type of analysis, and it is so dependent on the order of battle concerned, that it is not possible to develop the problem completely here, but the analyst's ingenuity should suggest the many applications.

(2) *Book messages.* Book messages are of particular interest because it is likely that some relationship exists between the various recipients which causes them to receive the same message. Some inferences can be made if something is known of any of the elements, such as the originator, a few of the recipients, or the use of the cryptographic system. A message, for example, passes from A to B, C, and D. A is an Army Hq., and B and C have been identified as divisional locations. Then it is probable that D is the third division of the Army. On the other hand, if the cryptographic system involved is one used by water transport units, it may be that D is included as a water transport unit which is handling the movement of some men for the two divisions.

c. Cryptographic Systems. If a cryptographic system is associated with a certain type of unit or with a definite unit and its subordinates, it will serve as an identification. For example, a system may be employed only by headquarters of Army or higher. Thus, every location sending in this system is probably Army or higher. Receiving in a system cannot be regarded as good evidence unless

REF ID:A58489

it happens in some volume, because of the possibility of a sender's error. To send in a system it must definitely be held, but receiving in it only implies that it is held. Systems restricted to Air Force, or supply, etc., may similarly be used to infer the nature of the unit at the location under study.

d. PATTERN OF SIGNAL FEATURES. These patterns may be of any type and concern almost any signal item. Three-letter calls, for instance, may only be assigned to Air Force units, or the manner of assignment may reflect the echelon of command. The same holds true for routing codes. Serial numbers which are 5-digit may be used by higher units, while 4-digit are reserved for division or below. Here again the possibilities must be developed to fit the individual case.

e. VOLUME OF TRAFFIC. The volume of traffic originated and received by any one point is indicative of its importance. Consideration, however, must be given to coverage facilities and assignments so that the traffic counts are not unduly weighted.

f. CHATTER. Security breaches involving units or clues to units occur occasionally, and chatter should be carefully scanned for them.

77. Determination of Movement

a. CHANGES IN NET STRUCTURE. It is apparent that most changes in net structure result from a more fundamental change in order of battle. Items to be noted include:

(1) Appearance of new stations on the net which often indicates the addition of a new unit.

(2) Disappearance of old stations which may mean the deactivation or move of an old unit.

(3) Moves of radio stations which usually denote the redeployment of the using unit. In moves of this sort, there is often a period of several days, between the closing of the old station and the opening of the new, when the unit will be off the air.

b. CHANGES IN CONTACT RELATIONSHIPS. (1) *Traffic Associations.* Any change in the traffic associations of a location should be carefully examined as it may indicate a resubordination or the move of a unit. For example, Army HQ at A regularly sends traffic to a division HQ at B. This contact later changes, A to C, indicating the move of Army HQ to C or else the division to a different Army if A continues to show the characteristics of an Army Hq.

(2) *Book messages.* Changes in the pattern of recipients of book messages indicate underlying order of battle changes. This is particularly applicable in the case of routine traffic where a distinguishable message passes regularly to several locations. If, for instance, a routine situation report sent daily from A to B, C, and D, changes to B, C, and E, it may be assumed that the unit at D has shifted to E.

c. CHANGES IN TRAFFIC VOLUMES. Changes in the traffic volumes

REF ID:A58489

handled at a point indicate some sort of activity though other techniques must be employed to determine the nature of the activity. In order to watch for changes, a standard of traffic volume into and out of each location is established as normal. Any rises or drops suggest changes in the situation. For example, a location handling an average of three or four messages per day suddenly jumps to 50. It is apparent that units are moving in the vicinity, that preparations are under way for a move, or that it has assumed a more important role. And the possibility that it may be caused by the use of control traffic for the purpose of deceiving the analyst should not be overlooked. As a corollary to this, changes in the volumes of precedence traffic, or in the usual file times, may also be of significance.

d. Moves of Serial Ranges. A message or signal center serial range, which is sufficiently distinctive, may be used as an indication of unit moves. For instance, an Army located at A is employing message center serials running 563–581 on the 10th. On the 12th, messages with serials 585–593 are observed originating at B, suggesting the Army's move to B.

e. Moves of Cryptographic Systems. Similar to the move of serial ranges, the move of a characteristic cryptographic system often signifies an order of battle change. A one-time pad, for instance, held only by a certain division and appearing on messages out of location A, suddenly is noted out of location B.

78. Identification of Units

The initial identification of units usually does not result from traffic analysis. Rather traffic analysis furnishes the means for following a unit about, once it has been identified. But, through the study of net, contact, and cryptographic associations (and the use of other signals features when applicable) it is often possible to define the nature and the echelon of a unit at a given location, and in some cases to name it. Chatter, also, may furnish the specific designations of units through breaches of security.

79. Conclusion

The traffic analysis techniques discussed in this manual require considerable study. It is difficult to cover a subject of this type, where so many individual bits and pieces must be fitted together, in text form since, in order to convey effectively the concept of traffic analysis, no one part should be presented before the other but rather the whole presented at once. For this reason, the text should be read and re-read. It is further to be noted that this manual is chiefly a theoretical text, that the field is still expanding, and that it is the task of the individual analyst to devise the applications best suited to his specific problems.

SUBCOURSE OVERVIEW

This subcourse is designed to teach you the basic concepts and minimum equipment requirements of radio direction finding (DF) as it is practiced in the Army today. The applications of DF are varied, with each application having its own requirements. You will be introduced to the basic terms and concepts of DF necessary to understand its application to other specialists or to prepare for the complete DF course.

There are no prerequisites for this subcourse.

TERMINAL LEARNING OBJECTIVE

ACTION: You will select the basic terminology/concepts of DF, and select the basic equipment requirements for a radio DF system and certain concepts needed for discussion of DF equipment.

CONDITION: You will use information provided in this subcourse.

STANDARD: To demonstrate competency of this task, you must achieve a minimum of 70 percent on the subcourse examination.

REFERENCES: The material contained in this lesson was derived from the following publications:

FM 34-40-0(U)	FM 11-666

LESSON 1

BASIC TERMINOLOGY

CRITICAL TASK: None

OVERVIEW

LESSON DESCRIPTION:

Upon completion of this lesson you will be able to show your understanding of the basic terminology and concepts of direction finding by matching terms and concepts with correct explanations.

TERMINAL LEARNING OBJECTIVE:

TASK: Identify with the basic terminology and concepts of direction finding.

CONDITION: Given the information provided in this subcourse.

STANDARD: To demonstrate competency of this task, you must achieve a minimum of 70 percent on the subcourse examination.

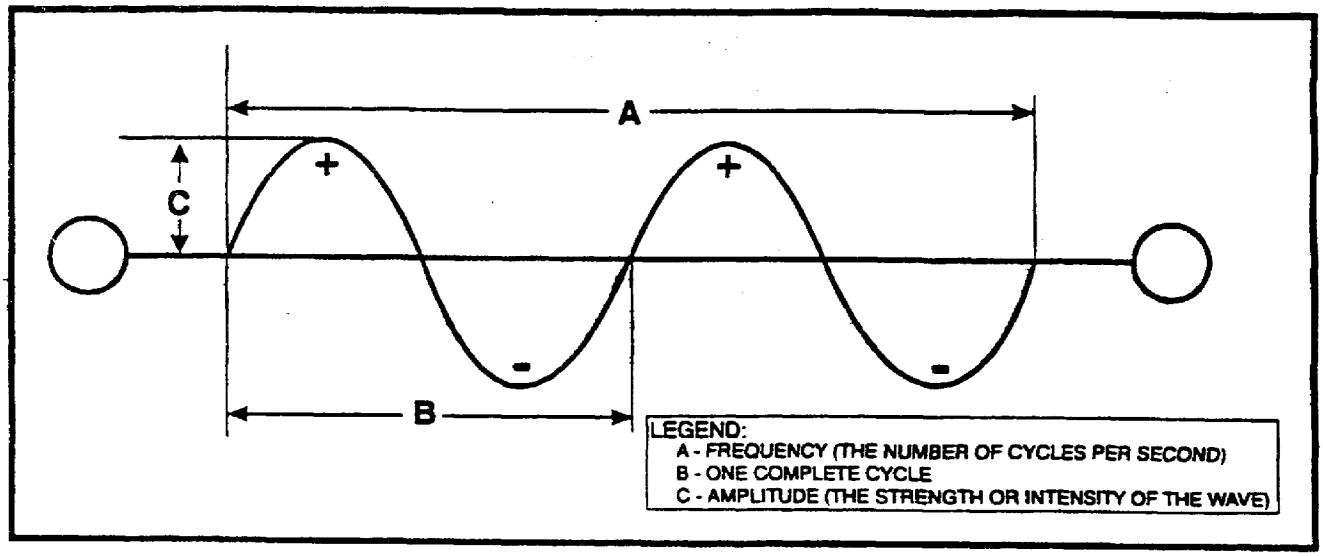
INTRODUCTION

Radio direction finding deals with the direction of arrival of radio waves. Therefore, it is necessary to understand the basic principles involved in the propagation of radio waves from the transmitting station to the DF equipment.

PART A: RADIO WAVE PROPAGATION

The distance traveled by a radio wave during a single cycle is known as a wavelength. A wavelength can be expressed in any unit of measure. However, it is normally expressed in meters. The number of complete waves that move past a given point in one second is called frequency. A unit of frequency is called Hertz (Hz). One unit is equal to one cycle per second Figure 1-1). The radio wave's strength or intensity is called its amplitude.



The radio wave, which is electromagnetic in nature, consists of an electrical field (E field) and a magnetic field (H field). Each field supports the other, and neither can be propagated by itself. Table 1, lists frequency bands, their designators, and the commonly accepted limits of each band.

The direction of the E field of a radio wave, relative to the ground, determines the polarization of the wave. Polarization can either be horizontal, vertical, or a mutation which adopts portions of vertical and horizontal. The later results in a circular or hybrid form of a wave. If a whip or other vertical type transmitting antenna is used to propagate radio waves, the transmitted wave is considered to be vertically polarized. If the transmitting antenna is horizontal, relative to the earth's surface, the transmitted wave is horizontally polarized.

Table 1. Frequency range and band designator.

FREQUENCY RANGE		BAND DESIGNATOR
3-30	kilohertz (kHz)	very low frequency (VLF)
30-300	kHz	low frequency (LF)
300-3000	kHz	medium frequency (MF)
3-30	megahertz (MHz)	high frequency (HF)
30-300	MHz	very high frequency (VHF)
300-3000	MHz	ultra high frequency (UHF)
3-30	gigahertz (GHz)	super high frequency (SHF)
30-300	GHz	extremely high frequency (EHF)

To illustrate vertical wave polarization, imagine a rope lying reasonably straight on the ground. One end is attached to a tree or other support (Figure 1-2). If the loose end of the rope is raised, tightened, and given a violent up and down motion, a series of undulationing waves will travel along the rope. The movement of the waves will be vertical to the earth and clearly visible.

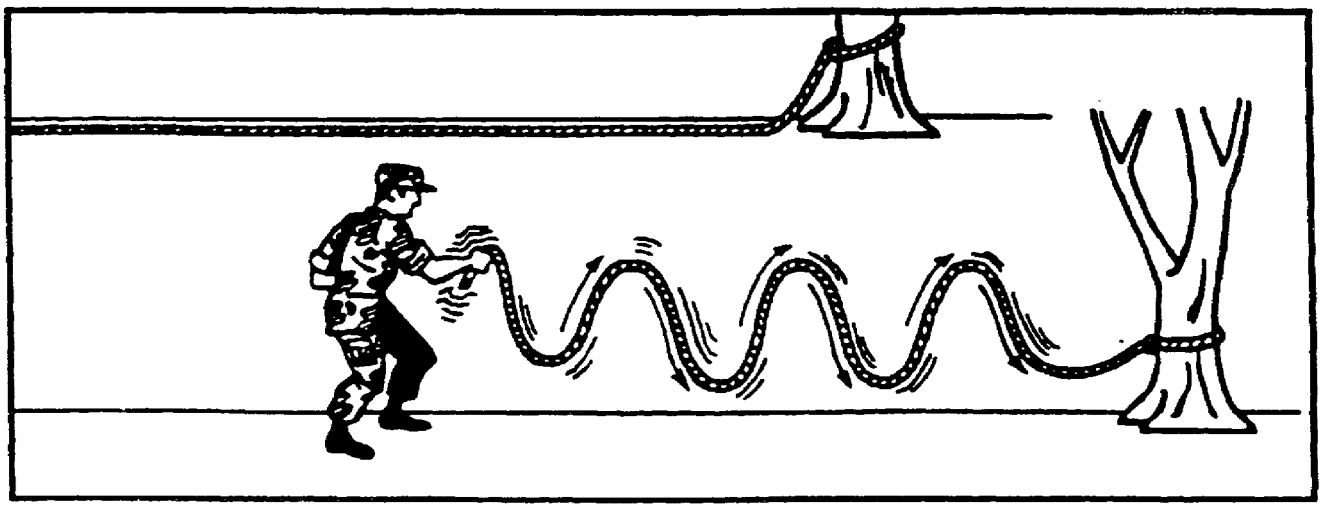


Figure 1-2. Vertical wave polarization.

If the same rope had a similar movement applied in a horizontal manner, the waves would be in a horizontal plane. These waves would be called horizontally polarized (Figure 1-3).

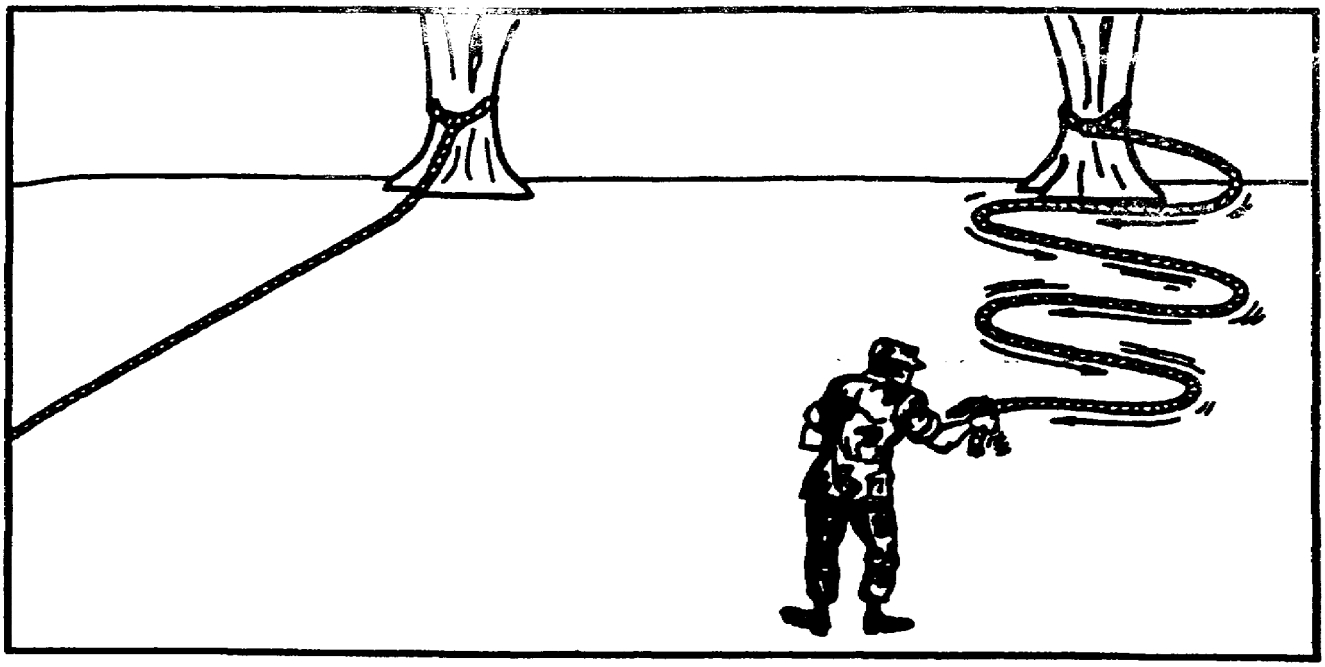

Figure 1-3. Horizontal wave polarization.

Wavelength, frequency, and polarization are all essential elements of the actual wave and are factors which affect the radio wave propagation. The simplest form of propagation is through space. Radio waves tend to travel in straight lines unless they are acted on by some force. They can be reflected off the surface of any sharply defined object such as the earth's surface. The radio waves can also meet other obstructions or objects that will scatter or reflect the signal. They can be reflected, refracted, or diffracted.

Radio waves are reflected similar to light waves traveling at the same speed. Although light waves can be seen, radio waves must be detected by electronic equipment. Figure 1-4 illustrates how radio waves are reflected off the ionosphere.

Refraction can best be illustrated by a pencil held obliquely so that a portion of it is beneath the surface of some water (Figure 1-5). From most viewpoints, the pencil will have the appearance of being bent at the point where it enters the water. This effect is because light waves travel more slowly in water than air.

Diffraction of a radio wave is the phenomena of bending the wave around a solid object. The lower the frequency or the longer the wavelength, the greater the bending of the wave. Therefore, radio waves are more readily diffracted than light waves. Sound waves are more readily diffracted than radio waves. This illustrates why sound waves can be heard around the corner of a large building.

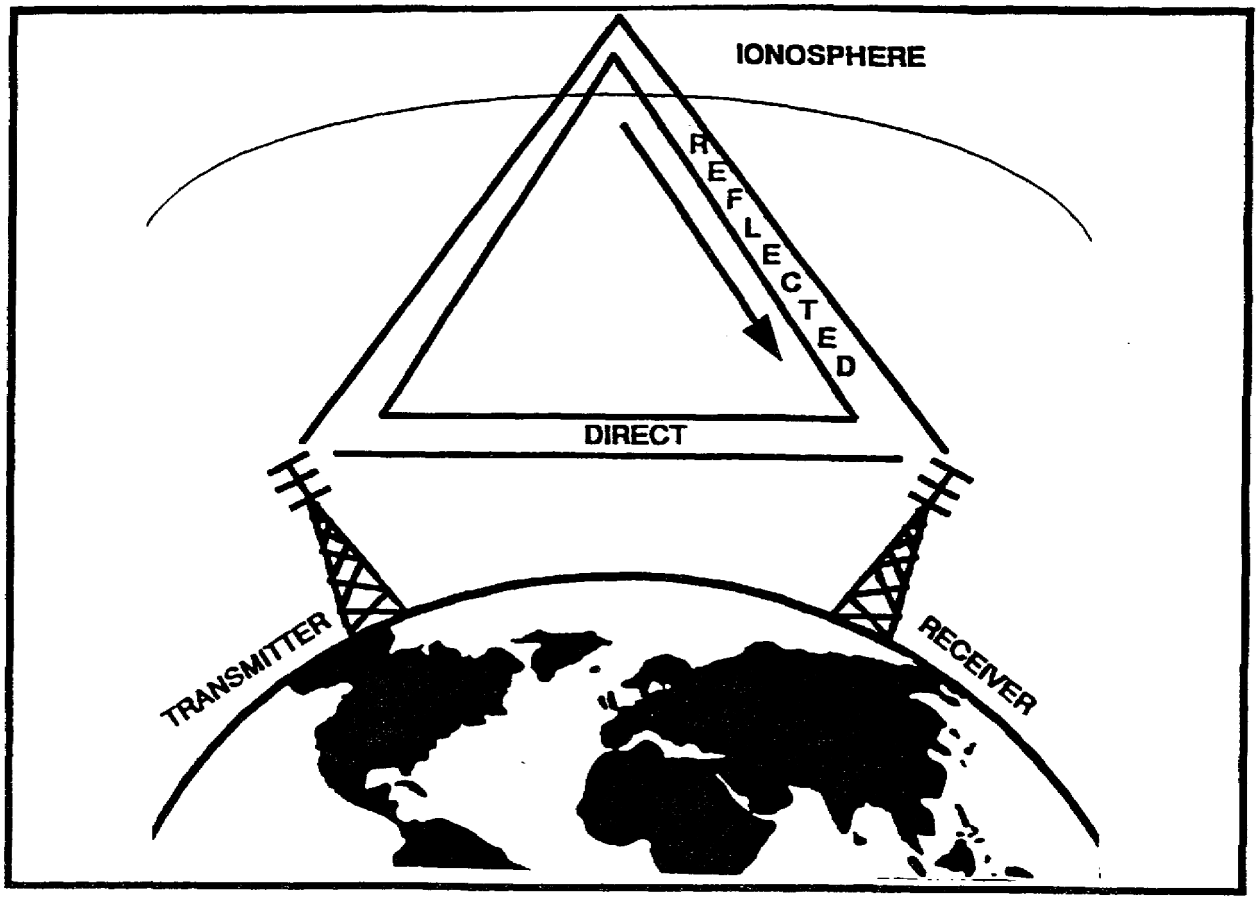

Figure 1-4. Reflected radio waves.

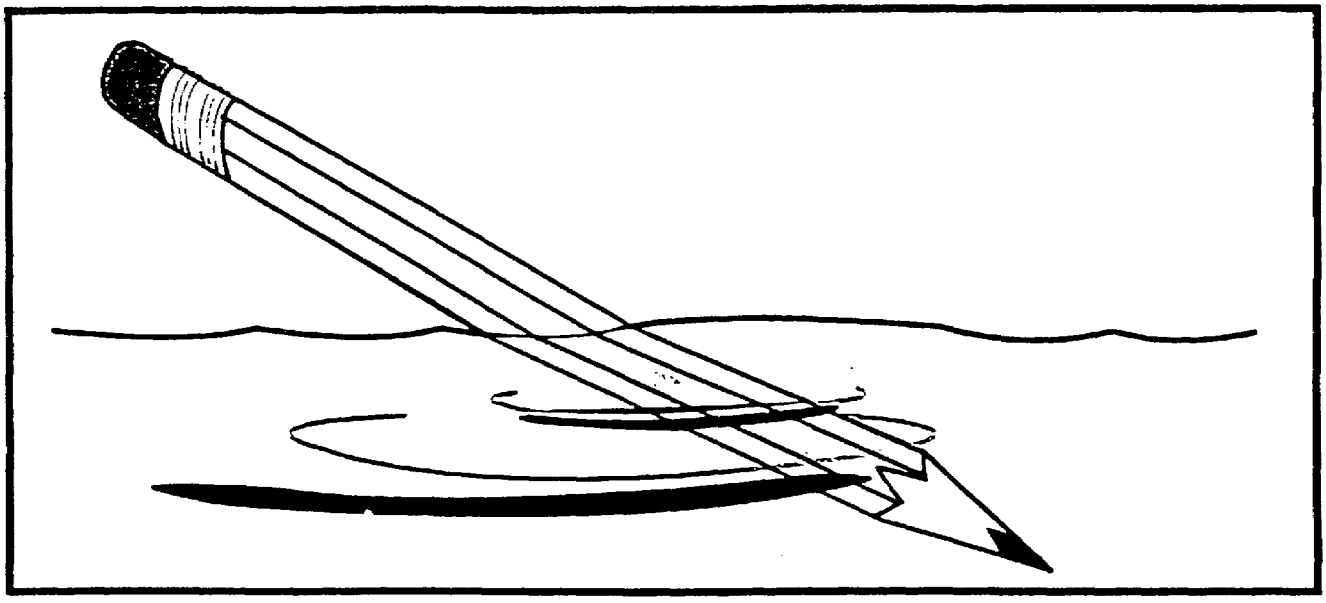

Figure 1-5. Refraction of a pencil.

The earth's atmosphere plays a crucial role in long distance radio communications. Radio waves may be reflected in the atmosphere and returned to earth. This technique is discussed later in this lesson. As shown in Table 2, the atmosphere consists of multiple layers, of which only a few have any discernible effect on radio waves. The ionosphere is the primary layer that is used to return a radio wave back to earth.

Table 2. Characteristics of the atmosphere.

ATMOSPHERIC REGION	LOCATION (Km)	FEATURES	EFFECT ON COMMUNICATIONS (Radio Frequency)
Ionosphere	Extending 50-600 km from the earth's surface.	Electrically charged set of layers, with large amounts of free electrons.	Excellent reflection/refraction of MF and HF signals. Some VHF may be propagated as well. Primary medium for sky wave communications.
Stratosphere	Extending 15-50 km from the earth's surface.	The only isothermal region of the atmosphere.	No effect.
Troposphere	From earth's surface to 10-15 km.	Lowest region of the atmosphere. Sustains life. Temperature decreases with increasing altitude.	Negligible effect. Allows direct, surface, and ground wave communications of all frequencies.

The ionosphere is a region of ionized (electrically charged) gasses located approximately 50-600 kilometers (km) above the earth's surface. As illustrated in Table 3, there are essentially four layers (D, E, F1, and F2) of the ionosphere which affect communications and DF. These layers vary in ionization and height above the earth's surface, depending on the amount of exposure to the sun.

The ionosphere is formed when extreme ultraviolet light from the sun strips the electrons from neutral atoms in the ionosphere. Thus, the electrons become free (unbound), and the remaining atom becomes positively ionized. The free electrons reflect/refract radio waves of a certain frequency. Due to this process, the E and F layers become positively ionized.

However, the free electrons may attach to neutral atoms. When such attachments occur, the atoms become negatively ionized. This process is common in the D layer, making the region of the ionosphere negatively ionized. Factors which influence the ionosphere and its effect on radio waves include--

- The time of day.
- The seasons of the year.
- Solar flares.
- Magnetic storms.
- Certain man-made disturbances such as nuclear detonations.

An important relationship between radio waves and the ionosphere is that the higher the frequency, the less its tendency to bend. Depending upon ionospheric conditions and the angle of the signal's arrival at the ionosphere, the bending may be slight. The radio waves may not be sent back to earth (Figure 1-6).

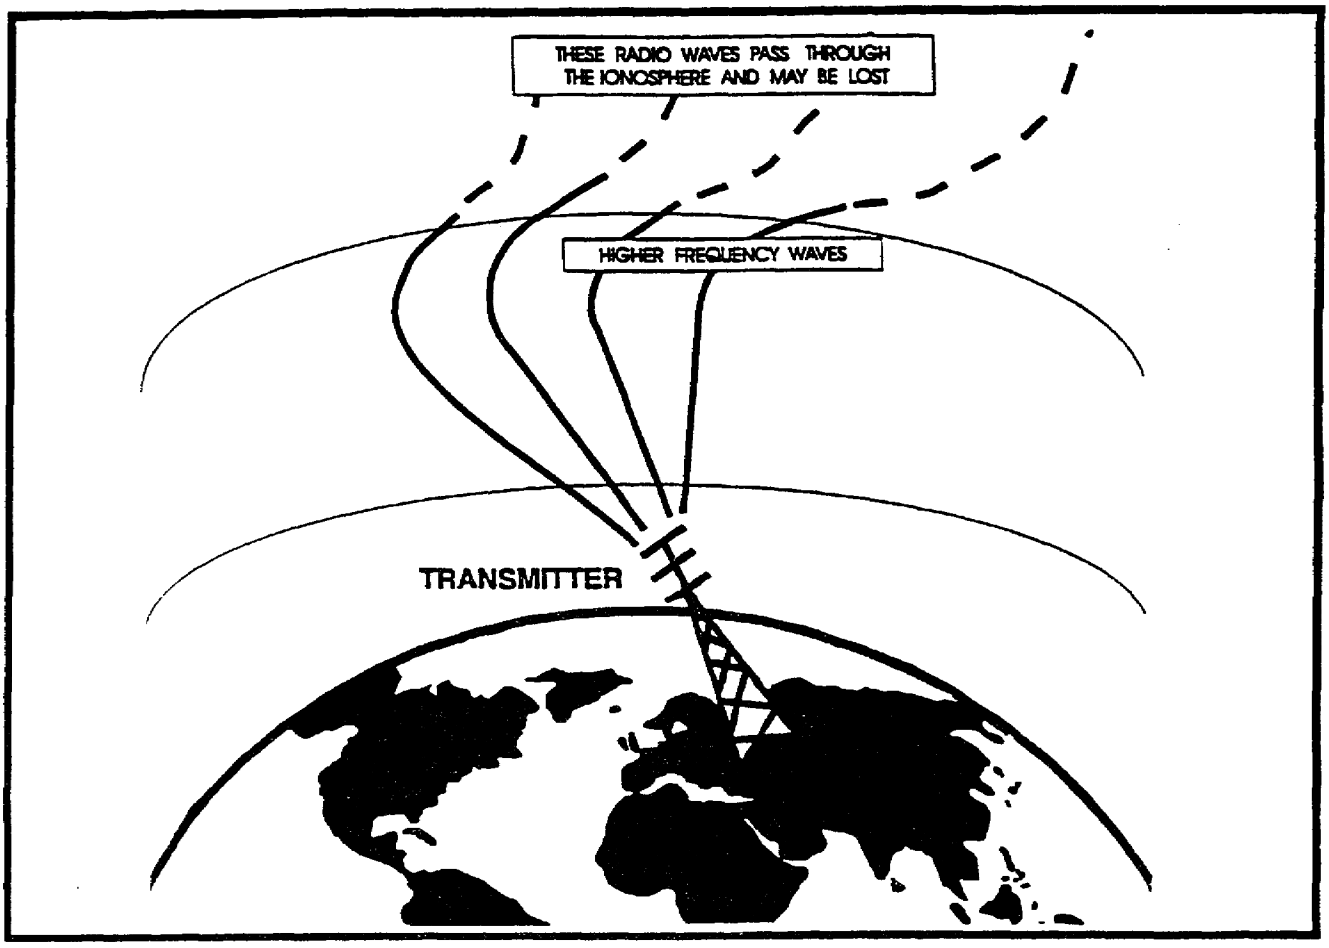

Figure 1-6. High frequency wave penetration.

During daylight hours, the ionosphere is subject to full ultraviolet output from the sun. Therefore, the D, E, F1, and F2 layers reach their full potential. At night, the composition of the layers of the ionosphere changes as the F layers combine. Therefore, higher radio frequencies are more likely to penetrate the ionosphere and be lost. As a general rule, lower communication frequencies are used during the night.

Conversely, during the day when ionization of the atmosphere is more intense, higher communications frequencies can be used without undue loss of the signal. This is because penetration of the ionized layer is at a minimum. Changes in the relative proximity of the sun to the earth will also cause gradual changes in the ionosphere.

Table 3. Characteristics of the ionosphere.

IONOSPHERIC REGION	LOCATION (Km)	FEATURES	EFFECT ON COMMUNICATIONS (Radio Frequency)
D	50-100 km	Layer closest to earth. Negatively ionized layer, with relatively little free electrons. Exists during the day.	Primarily acts to absorb radio waves. Small amounts of refraction are possible, but unpredictable.
E	100-200 km	Positively ionized with varying amounts of free electrons. State changes with temperature, angle of the sun, magnetic fields, and time of day. Exists during the day.	Erratic behavior. Sometimes reflects/refracts radio waves in MF, HF, and lower VHF bands.
F	145-400 km (F1-145-200 km) (F2-240-400 km)	Very positively ionized with large amounts of free electrons. During the day, this region separates into the F1 and F2 layers. The F region decreases in ionization and increases in altitude at night.	Primary means of reflecting/refracting MF and HF signals in sky wave propagation. At night, behavior becomes slightly erratic, but communications distances are much greater.

The longer exposure of the ionosphere to the sun in the summer causes a greater degree of ionization during the night and day. Therefore, higher frequencies may be used for summer operations.

Remember, however, that the actual number of layers, their heights above the earth, and the relative intensity of ionization present will vary. They vary from hour to hour, from day to day, from month to month, and from year to year.

There are three distinct paths that a radio wave may take to reach the receiving antenna. They are--

- Direct.
- Reflected.
- Refracted.

The direct and reflected paths are shown in Figure 1-7. They are purposely exaggerated to enable the reader to clearly grasp the differences.

The direct path goes directly from the transmitting to the receiving antenna. The reflected path bounces off the ionosphere or the surface of the earth at the same angle at which it arrives and continues to the receiving antenna (angle incidence=angle of arrival). The refracted path is the path caused by the bending of the waves in the same manner light waves are bent when seen through water.

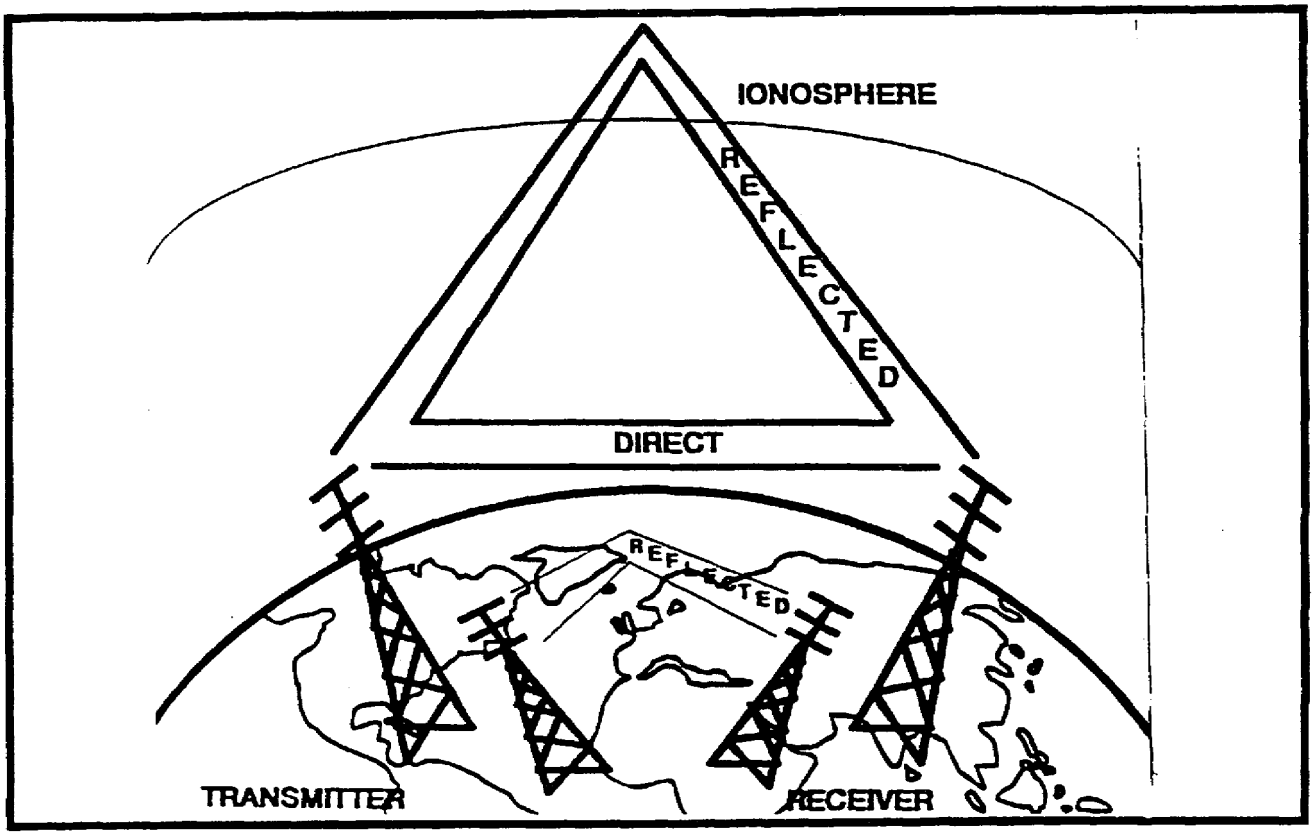

Figure 1-7. Direct and reflected routes for radio waves.

If the waves are refracted by the earth, the distance they travel is severely limited due to large losses of energy in the form of heat dissipated into the earth's crust.

Radio waves may be classified as either ground waves or sky waves (Figure 1-8).

Ground waves are continually in contact with the earth's surface. They do not make use of reflection from the ionosphere. They have a tendency to be refracted and, in some cases, reflected into the lower atmosphere. At frequencies above 1500 kilohertz, a ground wave is affected very little by the time of day or season. The ground wave loses much of its strength and dissipates energy as it travels over the earth's surface. However, less strength is lost when it travels over water.

Sky waves are transmitted upward with respect to the earth's surface. Sky waves would not be useful for communications were it not for the ionosphere. Radio waves approaching the ionosphere at an angle are refracted back to earth. They may be detected and used for communications purposes or for DF exploitation.

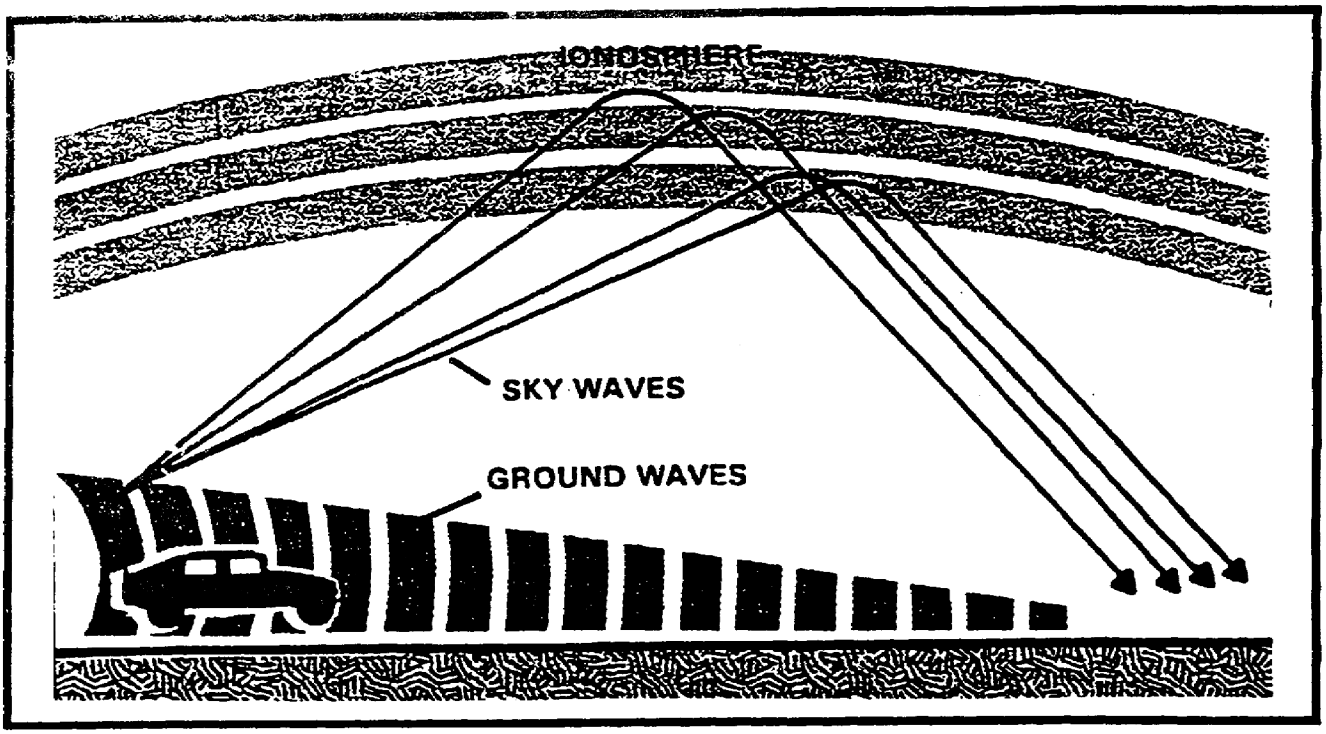

Figure 1-8. Ground waves and sky waves.

The skip zone is the area where the ground wave can no longer be detected (Figure 1-9) and the sky wave has not yet returned to earth after being reflected or refracted off the ionosphere or troposphere. The skip distance is that area where no sky wave reception will be possible. This is because the wave has not returned to earth after its first or subsequent bounce off the reflecting layer.

Depending upon the frequency and the transmitter power, multihop transmissions are routinely used for communications. Figure 1-10 illustrates multihop transmissions. There will be, however, skip zones between the points of the wave's return at each hop. Note, however, skip zones are not static or stable.

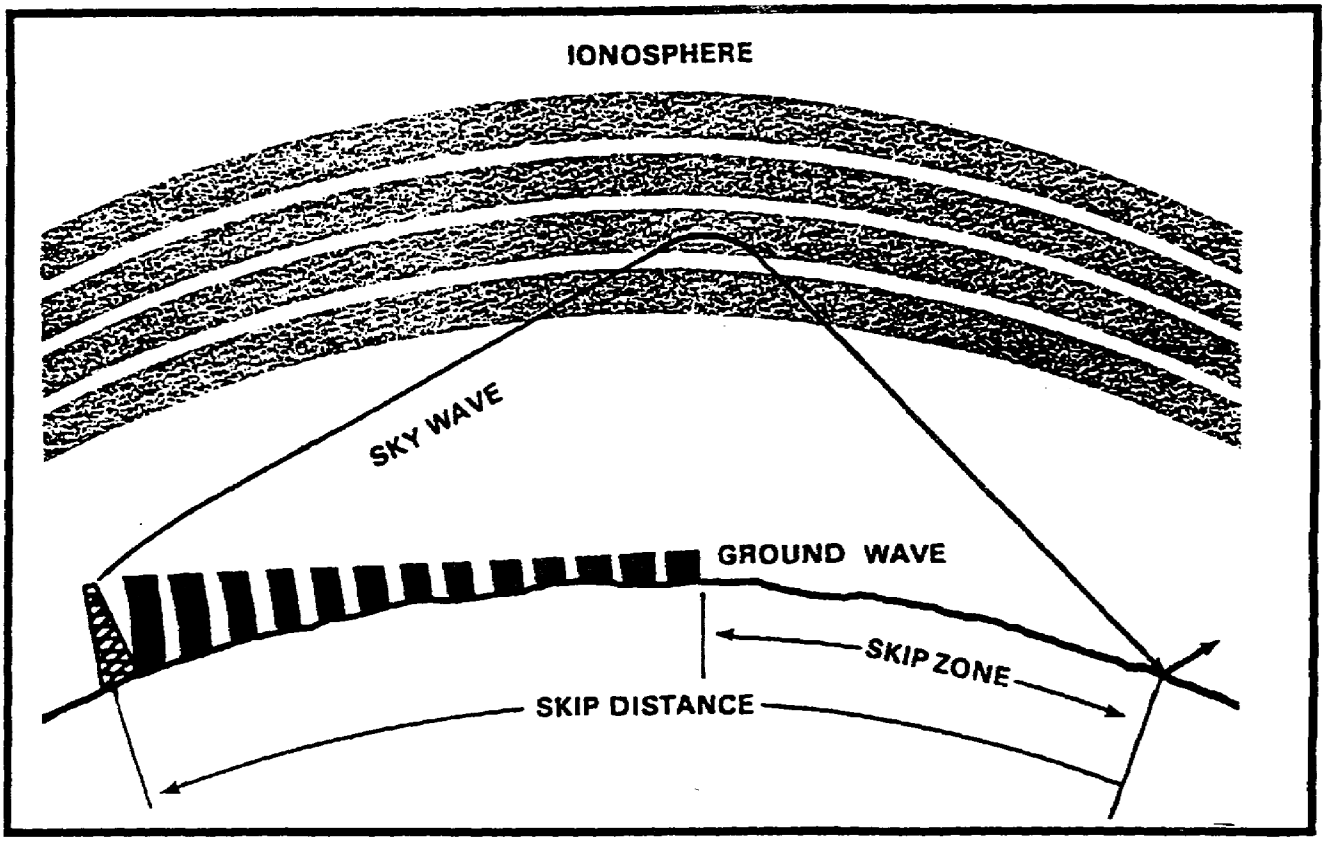

Figure 1-9. Skip zone and distance.

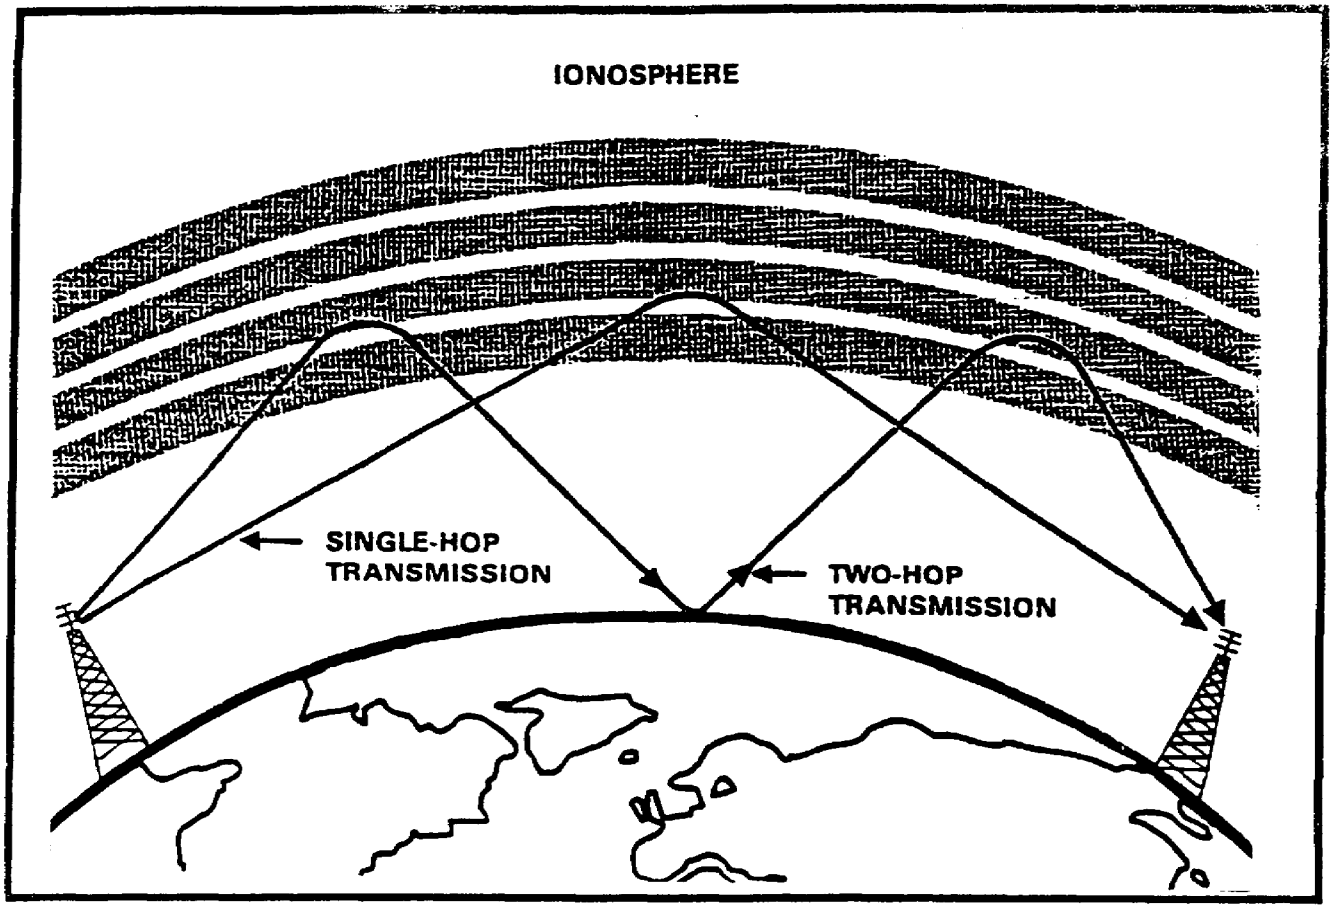

Figure 1-10. Multihop transmission.

PART B: PROPERTIES

Have you ever rotated a portable radio to find the best position to hear the station? If so, you are an experienced radio direction finder. The equipment was not very complex, but it met your requirements to get the results you wanted.

If you had turned the radio on full circle you would have heard two maximum and two minimum volumes. The reason for this is quite simple. The antenna in the portable radio is usually a bar-type antenna which is highly directional.

The pencil can be used to demonstrate the directional properties of the bar antenna. Hold a pencil in front of yourself with the pencil parallel to the ground. (See Figure 1-11).

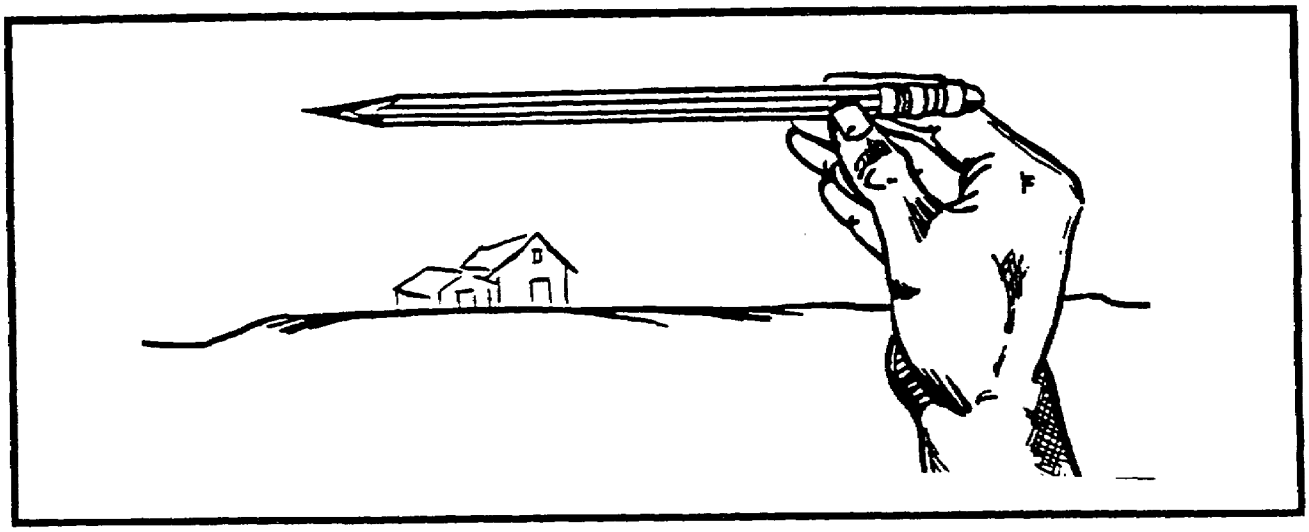

Figure 1-11. Pencil parallel to ground.

Keeping the pencil parallel to the ground, rotate it one full circle. Note that you see each end once and each side once, or put another way, the pencil is sideways to your twice and end on twice. In a bar antenna the sides give maximum reception (signal is loudest) and the ends give minimum reception. The minimum reception points are called NULL points and are important to direction finders because they are easier to hear and locate accurately than are the maximum signals.

The response pattern (a diagram showing the maximum and minimum areas of reception) for a bar antenna is a figure eight. The diagram in figure 1-12 indicates that the end points of the bar receive almost no signal, while the sides receive maximum signal. Since we are using our ears as aural indicators for signal reception, and since a minimum signal or NULL is easier to locate accurately than a maximum signal, we would use aural null indication to locate the transmitter. Of course the problem for a portable radio is locating the best reception rather than the least, but the principle is the same.

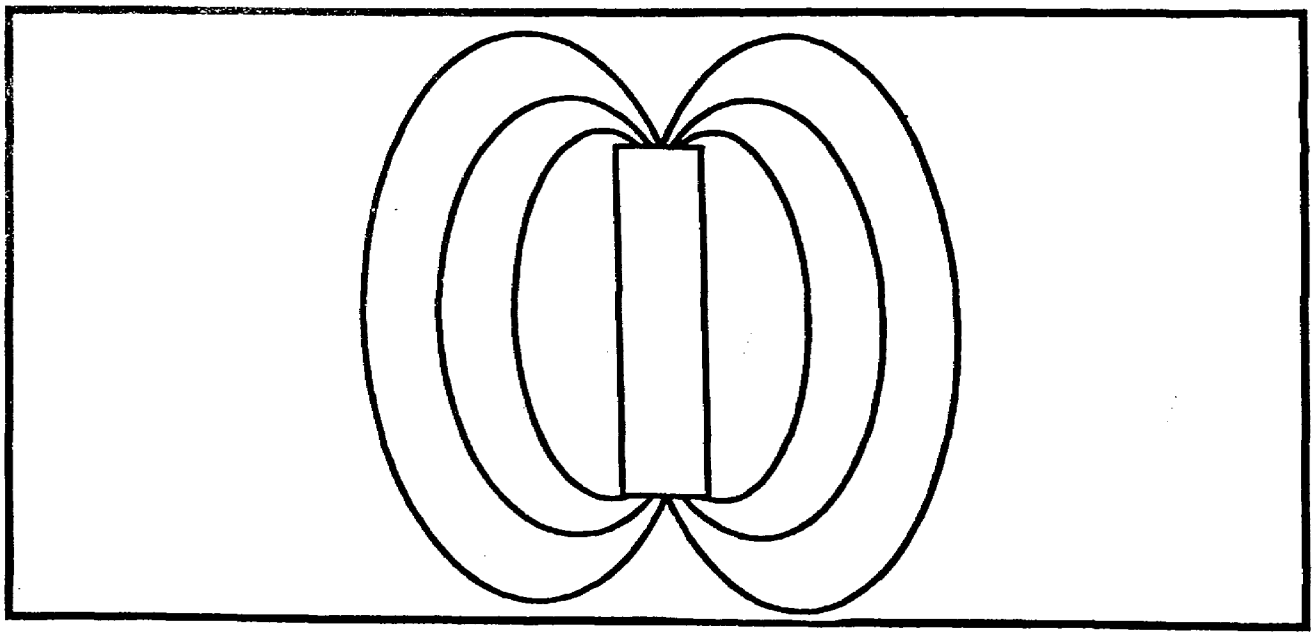

Figure 1-12. Response pattern for a bar antenna.

If we had some sort of compass or direction indicator on the radio we would have a complete direction finder. There is one other factor to be considered. We have two possible directions to choose from. This is the bidirectional ambiguity (the hard way to say it)(See Figure 1-13) which must be resolved (you must make a choice) for accurate direction finding. To do this we must add the signal input of another antenna (sense antenna) to the directional antenna giving us a cardioid (heart-shaped) pattern. This takes away one of the nulls, allowing us to decide which direction to choose. (See Figure 1-14).

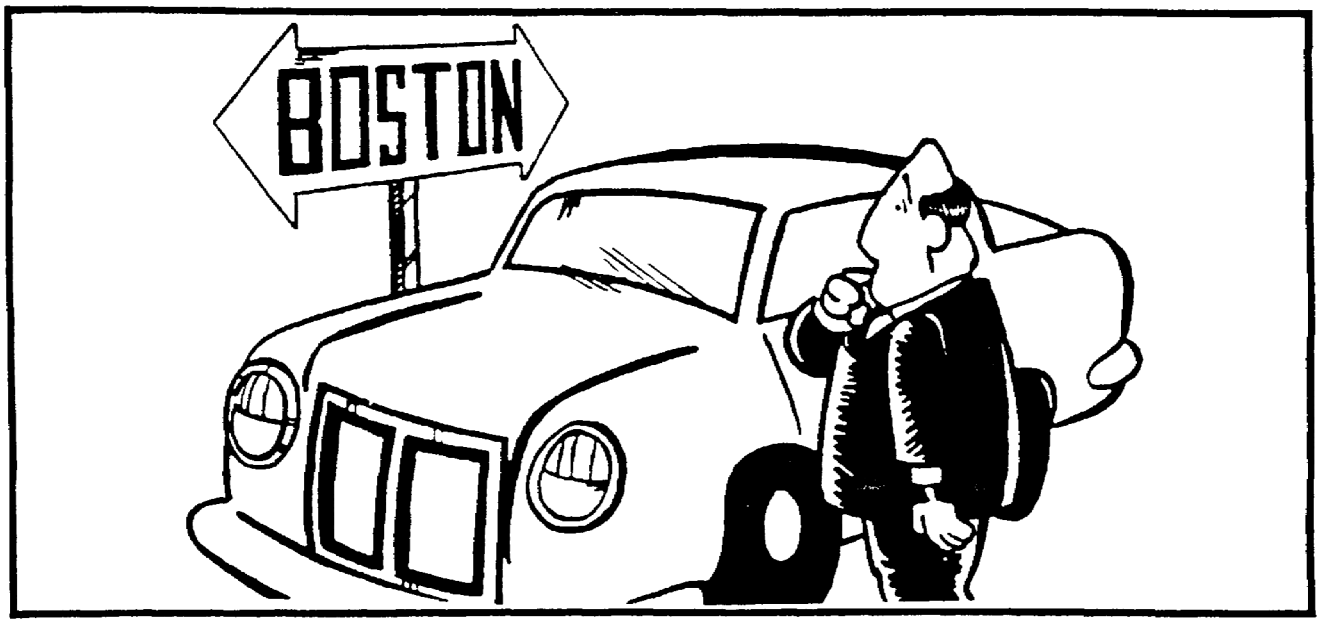

Figure 1-13. Example of bidirectional ambiguity.

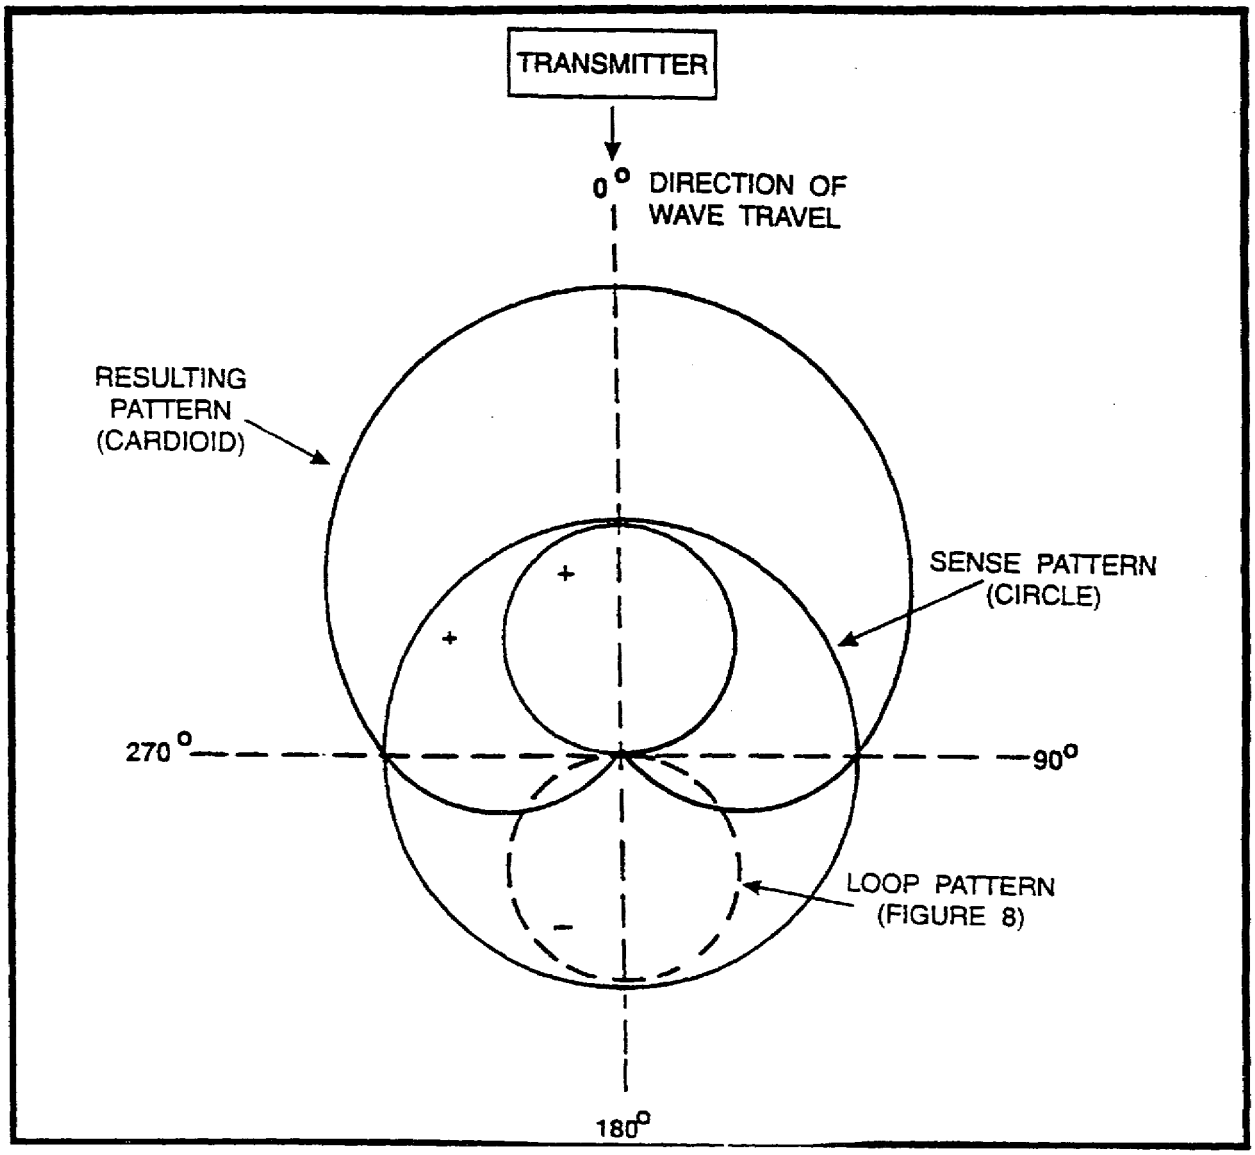

Figure 1-14. Combination of sense and directional antennas.

With the continual development of minicomputers and microprocessors, other methods of direction finding have become feasible. One common method of azimuth determination is Time of Arrival measurements. For this measurement, at least two antennas are used to form an antenna baseline. (See Figure 1-15).

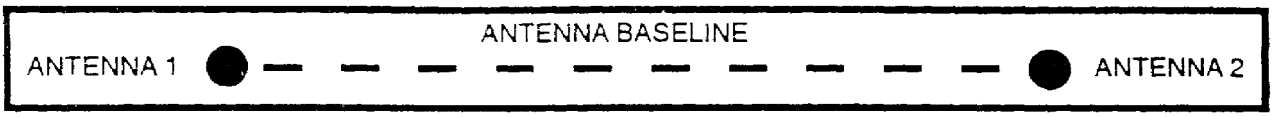

Figure 1-15. Antenna baseline.

As the wavefront strikes each antenna, a microprocessor measures the difference in the time of arrival at each antenna, and the angle of arrival is determined. (See Figure 1-16).

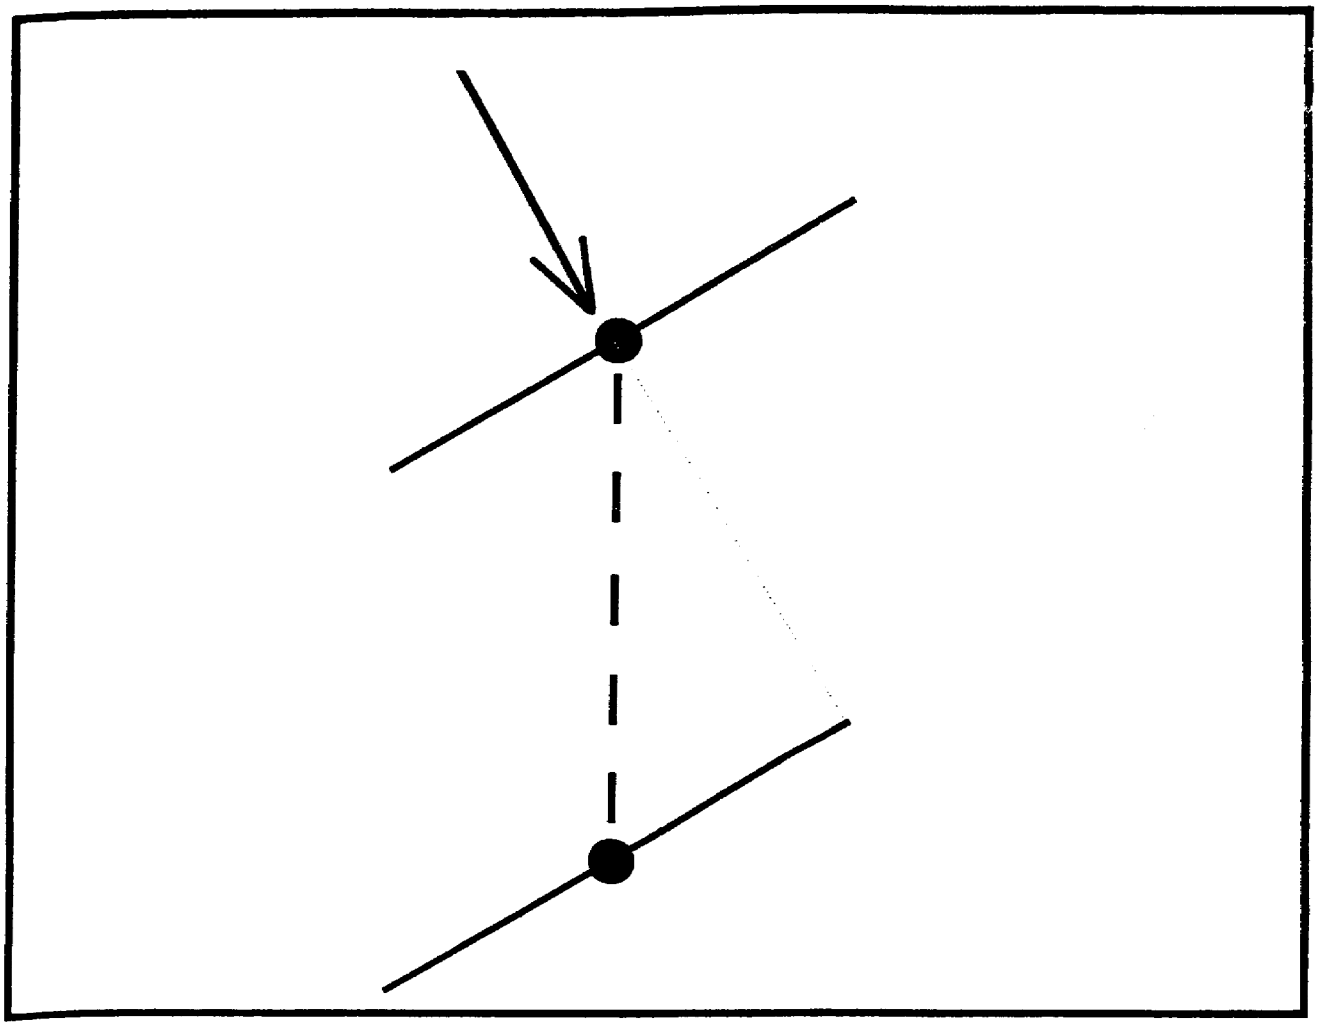

Figure 1-16. Angle of arrival.

As with the bar antenna, however, a possibility of bidirectional ambiguity exists with time of arrival measurements if the wavefront strikes both antennas at the same time. (See Figure 1-17).

To resolve this ambiguity, at least one more antenna is added to form one or more added baselines. (See Figure 1-18).

If a wavefront strikes antennas 1 and 2 at the same time, the ambiguity is resolved by measuring the time difference of arrival of the wavefront at antenna 3.

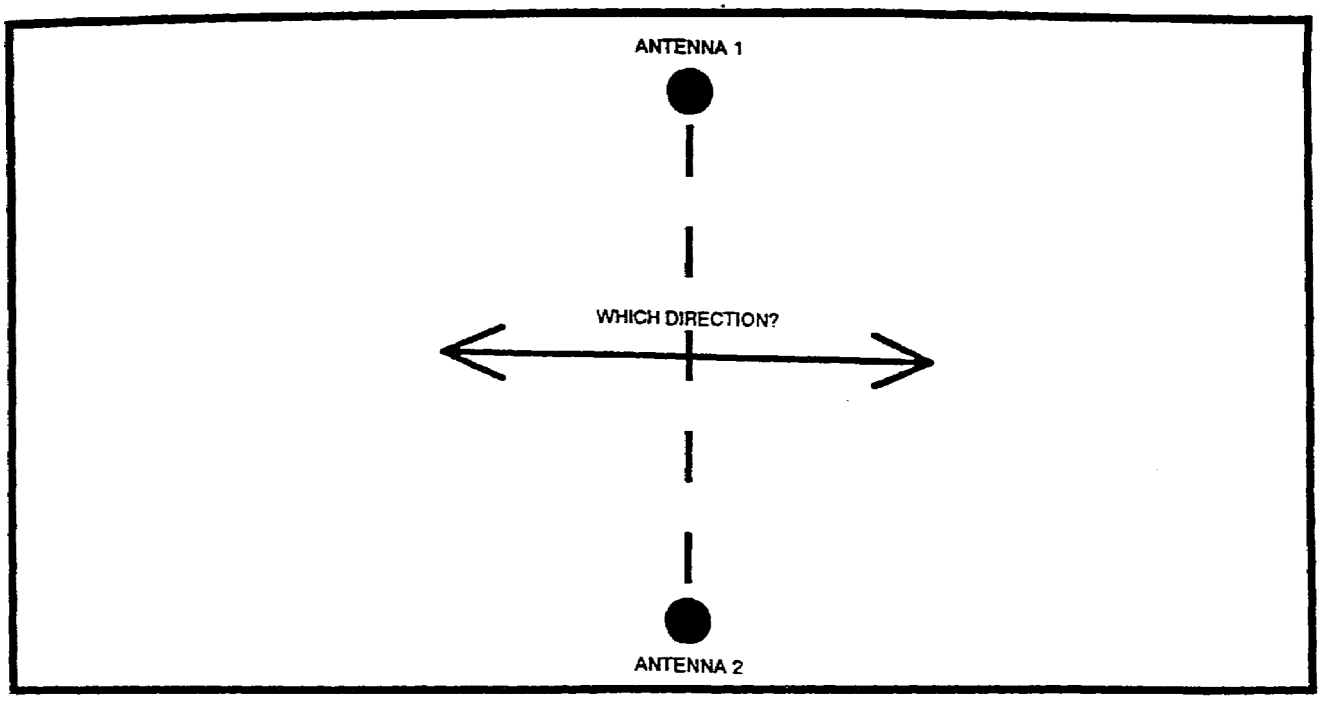

Figure 1-17. Bidirectional ambiguity.

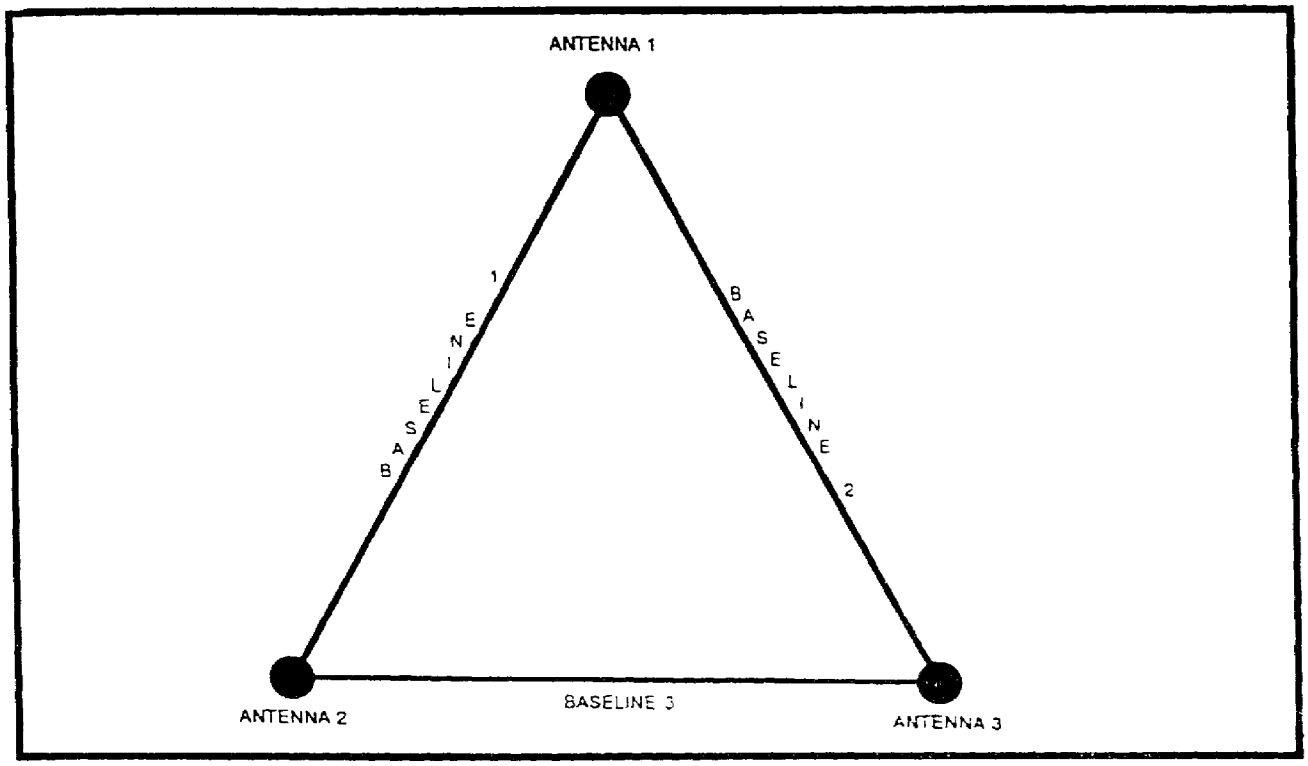

Figure 1-18. Antenna Baseline.

PART C: Elements

This is the basic theory of direction finding and the principle under which most direction finding is "determining the horizontal angle of arrival of a radio wave with respect to a known reference." The known reference is usually True North for strategic systems or Grid North for tactical systems. The horizontal angle is specified because other radio problems involve the vertical angle of arrival (how far to tilt the antenna for best reception) and arrival is specified because we want to know where it is coming from, not where it is going.

The determination of the azimuth is made by determining the angle of arrival, then measuring the angle between the point of arrival and the reference. This is called the azimuth or line of bearing (LOB) and has many applications. It can tell the operator the approximate direction to a transmitting antenna. If the direction finder is placed on a ship or aircraft, the vessel can "home in" on the transmitter. (See Figure 1-19).

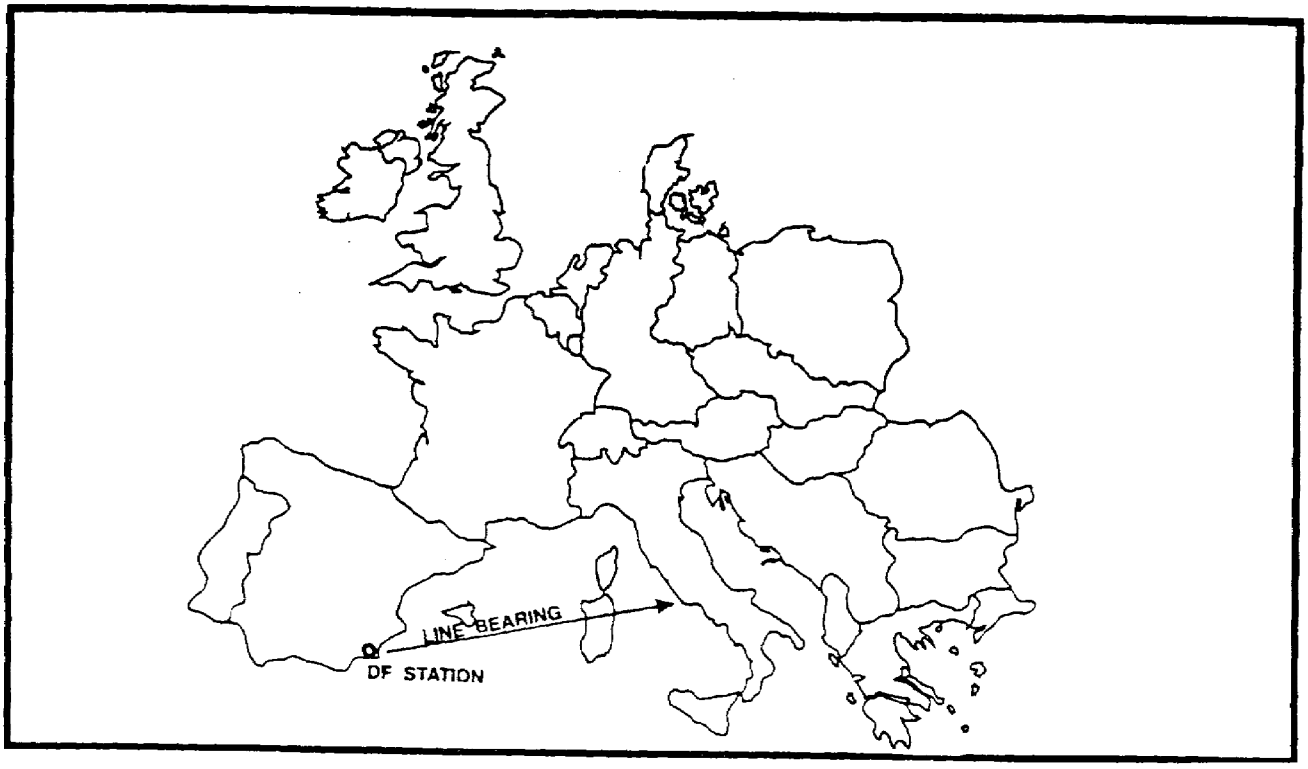

Figure 1-19. DF station line of bearing.

If we use two direction finders and take bearings with both at the same time we can locate a transmitting antenna with limited accuracy. The intersection of two azimuths is called a CUT and will provide the general location of the transmitting antenna. (See Figure 1-20).

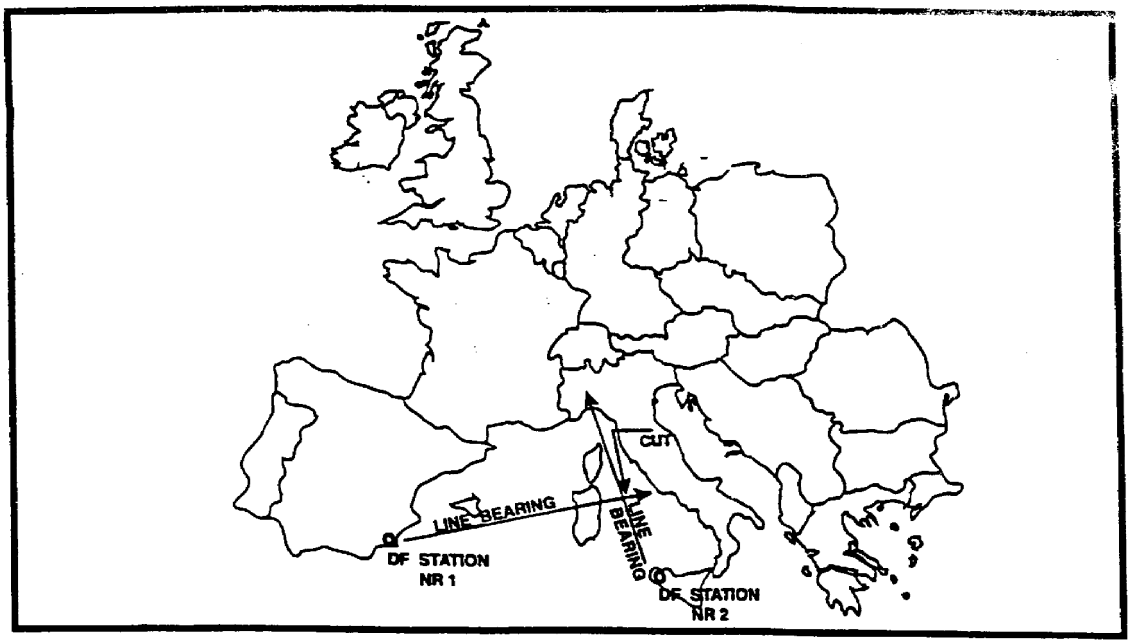

Figure 1-20. Cut of 2 DF stations.

For better accuracy in locating a transmitting antenna we must have three or more direction finders taking simultaneous bearings. This is termed a FIX, or FIX AREA, and will provide the probable location of the transmitting antenna. (See Figure 1-21).

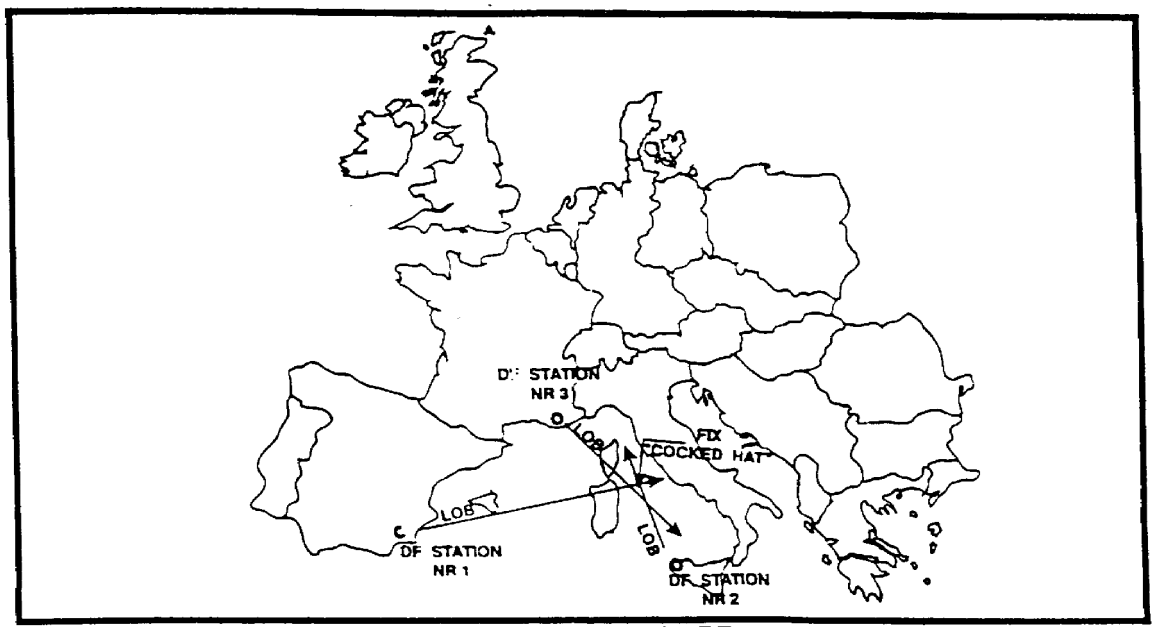

Figure 1-21. Fix area of 3 Led stations.

Note that we use the terms "approximate direction", "general location", and "probable location." This is necessary because of the many variables that affect direction finding. Your studies of radio wave propagation will find many causes of inaccuracies In direction finding. The most

accurate direction-finding equipment in use today has an equipment error of plus (+) or minus (-) 1 degree. This means that if there were no propagation errors to contend with, the equipment itself might cause an error of over 17 miles at a distance of 1000 miles. This problem of errors is taken up more fully in another course.

To be effective, direction finders must have access to listening posts or intercept stations, and must be tied together with a reliable high-speed communications system, and they must be carefully placed in well-planned locations. The spacing of these locations results in a BASELINE, which is important in respect to direction-finding net capabilities. The listening post will monitor several frequencies, and when a transmitter is heard, the direction finders will be notified using the communications system. If the direction finders are placed on a well-planned baseline they will be able to locate the transmitting antenna with a fairly high degree of accuracy. The baseline must be arranged so that the intersection of the bearings for a target located in the approximate center of the area of interest, will be close to 90 degree angles.

The azimuth from each direction finder is plotted on a map, the resultant enclosed area probably includes the location of the transmitting antenna. (See Figure 1-22).

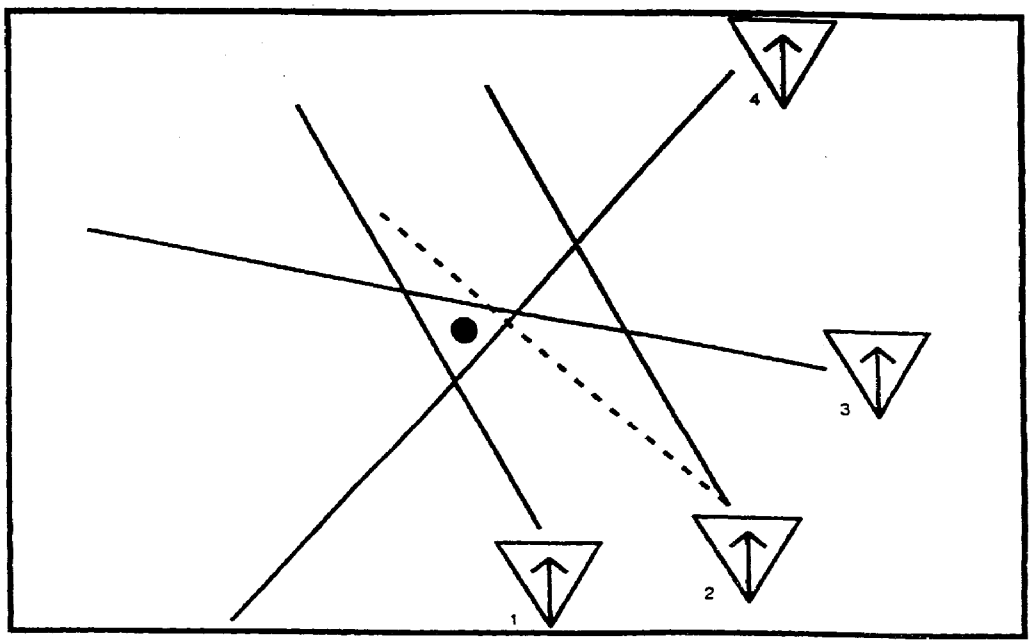

Figure 1-22. Plotted probable location.

The Chiefs of Staff of the Army and Navy have implemented a Joint Air-Sea Rescue Communication Plan (Joint Emergency Rescue Communication Plan JANY-10) which prescribes the procedure to be followed in establishing contact with shore DF stations. The services maintain high frequency DF networks along the various air routes. providing aids "fixes" to aircraft.

An evaluation center is associated with each DF network for the purpose of furnishing fixes and other navigational information to operations offices.

Radio direction-finding devices are used by ground force units for homing or positioning of patrols and reconnaissance units. Airborne troops also use these devices to regroup after landing. In many cases these devices are not complete DF units but simple devices attached to a common field radio receiver. DF is used to locate enemy aircraft in flight, ground control stations, and radio navigational aids. The results of DF correlated with other information comprise one of the most important sources of combat intelligence from which it is possible to determine the enemy order of battle when there is no physical contact. This information is usually more comprehensive than that derived from enemy radio stations. These stations are then monitored by DF for possible movement.

As demonstrated earlier, there are many types of direction finding systems. In some, only the azimuth of the arrival angle can be measured. In others, the azimuth and the elevation angle can be obtained. When only an azimuth is resolved, two or more independent DF stations are needed to determine the location of the transmitting antenna. Systems that measure both azimuth and elevation angles are called **single station locator** (SSL) systems. The SSL was developed because of the problems of audibility with the traditional DF network. Sometimes the signal could only be heard at one DF site.

The SSL system direction finder is a phase measuring interferometer. Location data include an azimuth measure on the target signal and a range estimate based on the measured parameters at the DF site. The combination of azimuth and great circle range to the target produces the location output from the system's computer.

Because the SSL system depends on ionospheric propagations, it is designed for use against the high frequency (HF) spectrum sky wave transmissions. As shown in Figure 1-23, the combination of an azimuth and great circle range to the target produces a location from the system that is expressed in geographic coordinates.

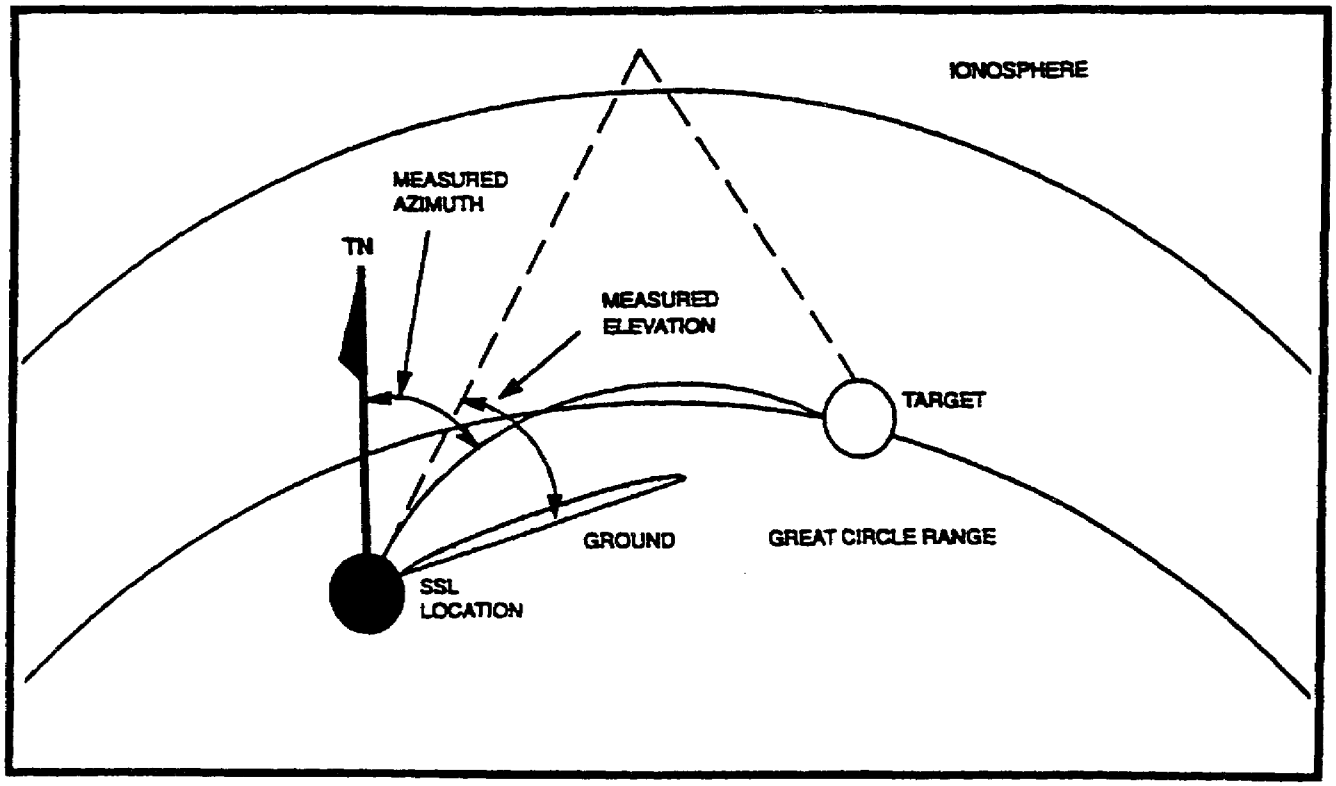

Figure 1-23. Single station locator DF.

LESSON 1

PRACTICE EXERCISE

The following items will test your grasp of the material covered in this lesson. There is only one correct answer for each item. When you have completed the exercise, check your answers with the answer key that follows. If you answer any item incorrectly, study again that part of the lesson which contains the portion involved.

1. What is a radio waves strength or intensity called?

   A. Consecutive Cycles
   B. Complete Wavelength
   C. Its Magnitude
   D. Its Amplitude

2. What does DF determine the direction of?

   A. Artillery Fire
   B. The arrival of a radio wave
   C. The direction a radio should be pointed for the best reception
   D. The distance of a receiver

3. What band designator would the frequency 200 MHz be in?

   A. HF
   B. VHF
   C. UHF
   D. SHF

4. What are the DF results with a range of 1000 miles called?

   A. Approximations
   B. Exact, if enough sites are used
   C. Reliable
   D. An indicator of general direction only

5. Which of the following is NOT used as a military application of DF?

   A. Positioning of ground forces
   B. Determining order of battle
   C. Location of communications systems
   D. Detection of chemical agents

6. What is the most common reference point for DF?

   A. The enemy front
   B. The friendly forces front
   C. Magnetic north
   D. True north or grid north

7. Which frequencies would you use for the best communications at night?

   A. Lower Frequencies
   B. Mid-range Frequencies
   C. Higher Frequencies
   D. Ultra High Frequencies

8. What is the accuracy of the most accurate DF equipment used today?

   A. +1%
   B. + 2%
   C. + 1 degree
   D. + 2 degrees

9. What is the term used for the intersection of two azimuths?

   A. Bidirectional
   B. LOB
   C. Cut
   D. Fix Area

10. Including an azimuth, what is also measured by a SSL system in order to determine the location of a transmitting antenna?

    A. Elevation Angle
    B. Ground Waves
    C. Target Area
    D. Skip-Zone

LESSON 2

EQUIPMENT REQUIREMENTS

CRITICAL TASK: None

OVERVIEW

LESSON DESCRIPTION:

In this lesson you will learn to identify the basic equipment requirements for a radio direction finding system and certain concepts needed for discussion of direction finding equipment.

TERMINAL LEARNING OBJECTIVE:

TASK: Identify the basic equipment requirements for a radio direction finding system and certain concepts needed for discussion of direction finding equipment.

CONDITION: You will use the information provided in this subcourse.

STANDARD: To demonstrate competency of this task, you must achieve a minimum of 70 percent on the subcourse examination.

REFERENCES: The material contained in this lesson was derived from the following publications:

INTRODUCTION

Radio direction finding equipment comes in all sizes and shapes, depending upon the requirements of the users. Some equipment can be hand-held, back-packed, or airborne (Figure 2-1) while other configurations require several acres of land for installations.

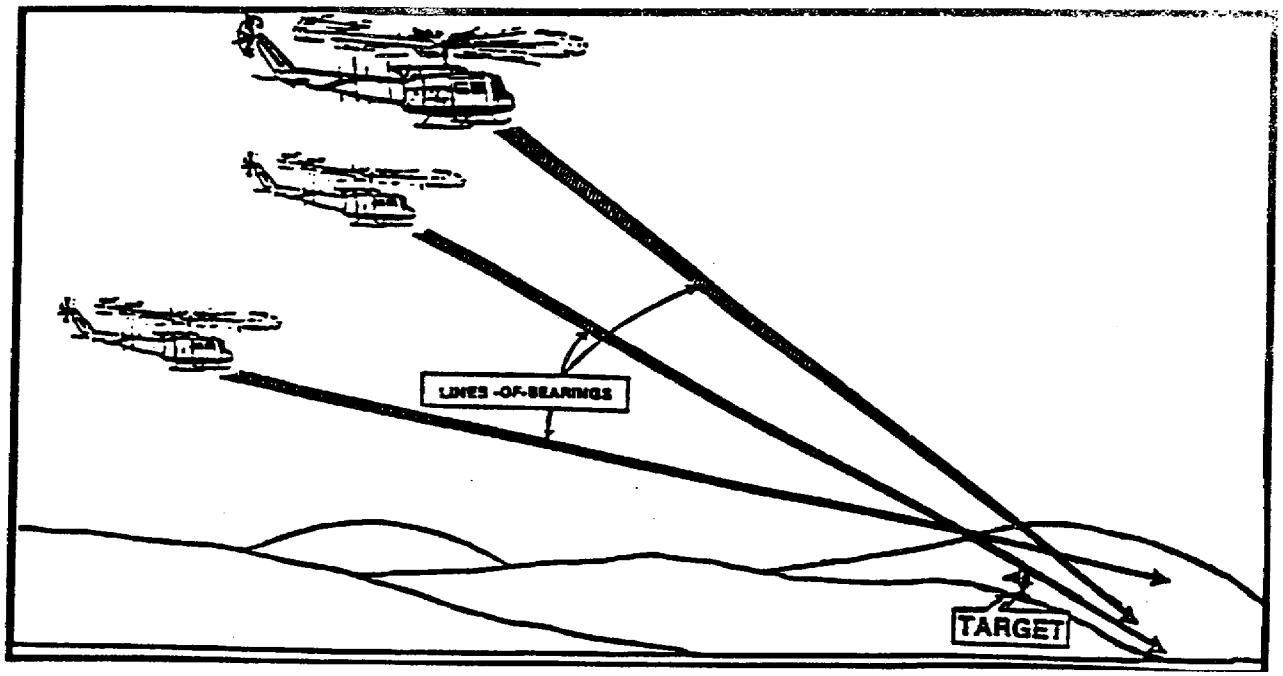

Figure 2-1. Airborne radio direction finding.

PART A: COMPONENTS

Regardless of the requirement, direction finding equipment will have the same basic components. (See Figure 2-2).

a directional antenna
a radio receiver
a coupling system
a method of indication

Suppose we refer to the portable radio mentioned in the first lesson. The directional antenna is the bar antenna. The receiver is the radio itself. The coupling system is the "direct coupling." The indication system is the "aural null." Each is designed for the specific job it is supposed to do, and is the most efficient piece of equipment the manufacturer can use within he parameters (requirements) needed. Probably the first consideration for the manufacturer was cost efficiency, second was size and weight. Third was ease of use. Fourth was neatness of design. There are others but our discussion will stop here.

The Directional Antenna. The bar antenna is the most compact for the frequency range of the receiver. It is highly efficient and relatively inexpensive, consisting of a number of turns of wire wound around a core. The fact that it is bidirectional was of secondary importance to the manufacturer, but it makes a net illustration for the DF student. Of course, the user of the radio is more interested in the peak reception than the null, but still the directivity is there and can be used. As an illustration of the case of use of the null, as compared to the maximum point, try lining yourself with the length of the antenna as compared with centering yourself on the width.

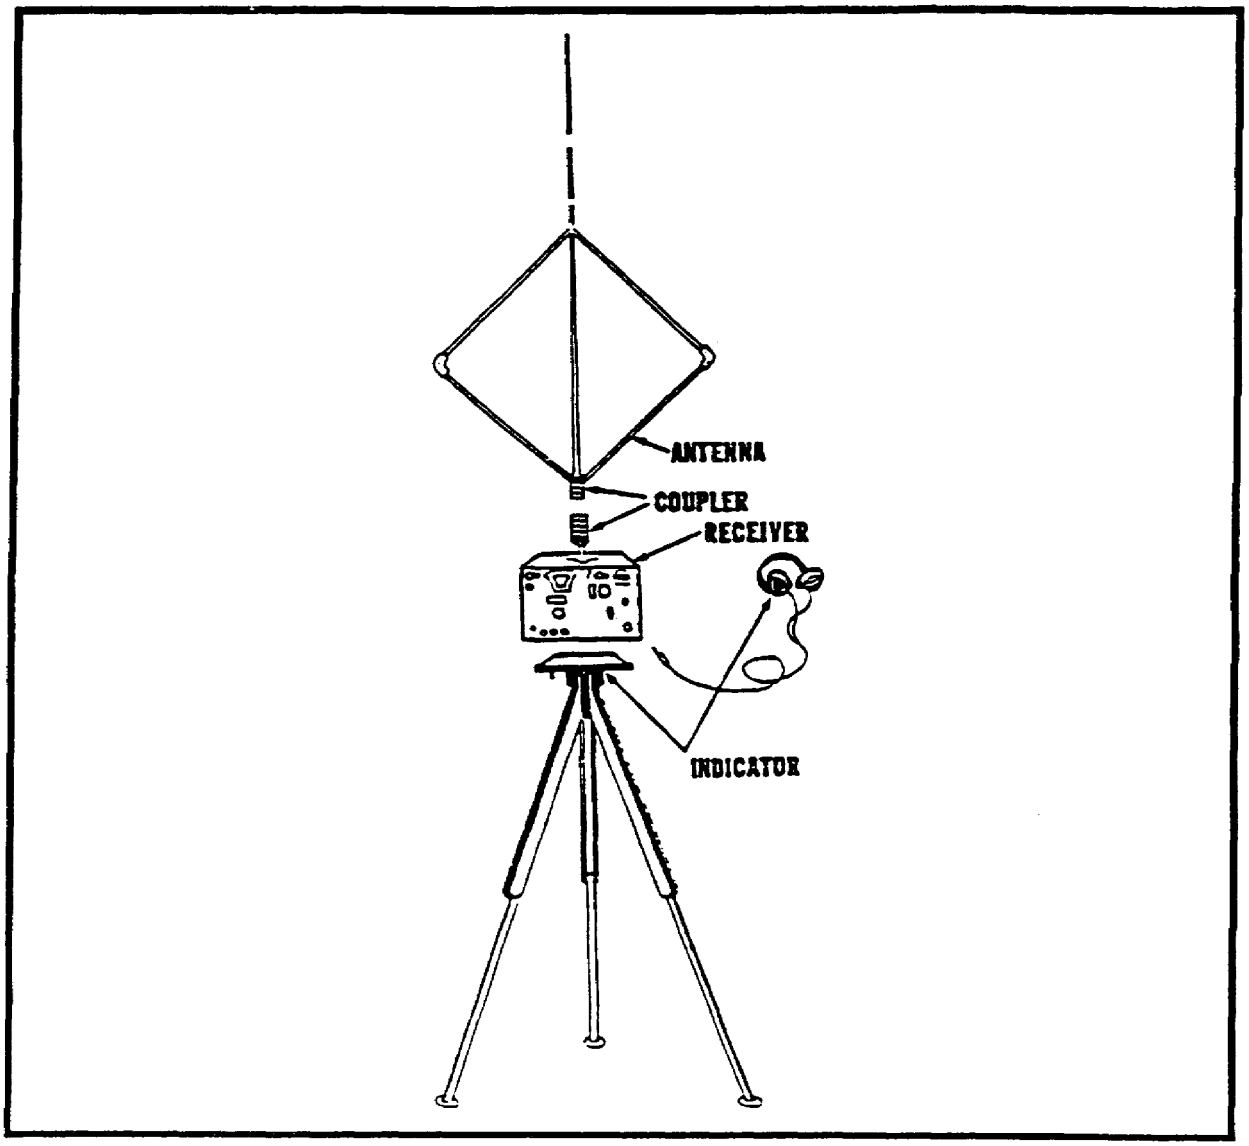

Figure 2-2. Basic components.

Or, put another way, if you hold a pencil you can tell where the point is by looking, but where is the exact middle of either side?

The coupling system. This is the device that connects the antenna to the receiver. The directional antenna must be rotated in a circle to detect the angle of arrival of the radio wave. If we were to use a simple antenna cable, it would soon twist until it broke. Several systems have been devised but all can be identified as either manual or electronic. The simplest system is the direct coupling in your portable radio. The problem is that it requires us to rotate the receiver as well as the antenna to determine the angle of arrival. This would be difficult with our large systems. Another manual coupling is slip ring and brushes. This is an antenna which is rotatable but maintains contact by means of brushes (such as in the generator of your car touching slip rings which allows the signal voltage to pass freely from the antenna to the receiver). For direction finding antennas that are too large to be normally rotated, a device

called a goniometer is used to electrically rotate the antenna. The leads from the antenna are connected to coils in the goniometer, and another coil is rotated in order to sample each portion of the circle in turn. Some of our VHF/UHF DF systems use a microprocessor or minicomputer to electronically measure the time of arrival instead of rotating the antenna.

The Radio Receiver. Your portable radio, whether it be a small Amplitude Modulated (AM) receiver or the larger, and costlier, transoceanic AM, Frequency Modulated (FM) shortwave type, is designed to receive broadcasts within certain wavelength imitations. These limits are called the frequency range of the receiver. Which receiver will be used with your DF system depends upon the frequency range of the transmitter in which you are interested. Another consideration is the desired mobility (how fast it can be moved without damage) and transportability (what does it take to move it) of the DF system. The DF receiver must have good stability (stays on frequency), sensitivity (you can hear and target), selectivity (you can tune out the signals you don't want), and a Beat Frequency Oscillator (BFO) which is used to give a steady tone for ease of direction finding/AM signals.

The input and output circuits of an ordinary communications receiver usually require modification for use with direction finders. The portable radio, for example, has the correct frequency range for the targets desired. It is designed to be hand carried, relatively stable, has selectivity, and is as sensitive as the price allows. It does not have a BFO, therefore, it does not meet our requirements. If we were to use it with our systems we would have to add a BFO.

The Method of Indication. By now you are familiar with aural null indication. The most common system other than aural null is visual indication. This employs a cathode ray tube or some type of meter which indicates the null or maximum signal for your interpretation. The indicator is usually associated with some sort of a measuring device so the operator can record what he/she sees or hears.

A useful direction-finding system must have these four components. The targets, and the tactical situation will indicate what combination and size of equipment can or should be used.

PART B: DEFINITIONS

Many of the terms used in discussing direction finding are unique to direction finding or are used in a different sense. In order to understand how these terms relate to the discussion that follows, you will need to know exactly what is meant by each of them. These terms relate primarily to a discussion of antenna theory.

(a) Loop. Originally a loop antenna was a circle of wire. Modern loops come in a variety of shapes but essentially and electrically they are the same as the original circle. It might be easier to think of the circle as a square, with vertical and horizontal sides, since the action of the radio wave on the antenna is discussed in terms of how it affects the horizontal and vertical members of the loop.

(b) Conductor. The wire or similar material used to pass current from one part of a circuit to another.

(c) Instantaneous voltage. The amount of voltage present at any given instant in an electric circuit. Differences in instantaneous voltages, or the lack of differences, give an antenna its directivity.

(d) Magnitude. How big, or small, strong, or weak, something is. For our purposes magnitude refers to the strength of an electric or magnetic field.

(e) Plane parallel to the wavefront. This concept is the biggest single stumbling block to discussion of wave theory the average uninitiated person finds. With reference to the path of the wave, even though the wave front (first part of the wave) is spherical by the time it has reached a reasonable distance from the transmitting antenna, the portion of the wave we intercept with our antennas is assumed to be a straight flat plane. If the wave is traveling toward us in a straight line the wave front is at right angles to the direction of travel. Look at a wall. The line to the wall (or move exactly from the wall to you) is the wavepath, and the wall is the wave front. If you were an antenna with your plane parallel to the wavefront, you would be turned so that the wave front would hit both arms at the same time, if the wall (wave front) went over you (the antenna).

(f) Plane perpendicular to the wave front (Figure 2-3). The loop antenna has been turned so that the incoming wave strikes one vertical arm before it strikes the other. If the antenna face is at the true perpendicular the voltages in use in the receiver are strongest, because the differences in the voltages in the opposing arms of the loops are greatest. This is because the wave will be at different intensities (strengths) for each arm of the loop.

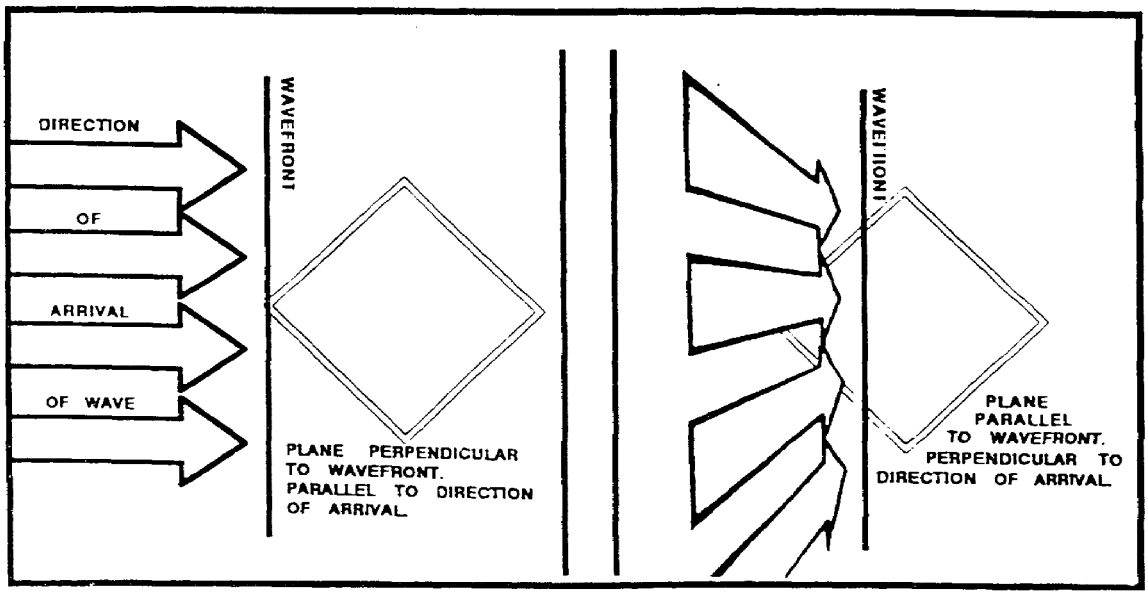

Figure 2-3. Plane perpendicular to the wave front.

(g) Spacing. The physical distance between the antenna elements. Spacing is usually measured in terms of the wavelength, which means that any antenna which is spaced properly for one frequency will not necessarily be spaced properly for another. Spacing is one of the principal limiting factors in determining the frequency range of a directional antenna.

(h) Sense. The addition of an equal voltage from another antenna to the response of a directional antenna. If the voltage added is equal to the original voltage the response pattern is changed to move the nulls to different places in the pattern. Because of this, it is possible to determine from which direction the signal is arriving.

(i) Response pattern. If a target transmitter were physically moved around an antenna, putting out the same amount of signal all the way around a circle at a fixed distance from the center of the antenna, the amount of signal received would vary according to the type of antenna being measured. If this variation is recorded on circular graph paper as so much volume equals so many lines on the graph, with a relationship between direction on the paper and direction in the field, a pattern results which indicates the response of the antennas at any direction. The whip antenna has a circular (omnidirectional) pattern.

(j) Omnidirectional. The response pattern of (for example) the whip antenna. All directions produce an equal response.

(k) Null. The point of weakest response or ideally no response. If the equipment is sensitive enough to allow critical measurement the system is said to have deep nulls. A system with broad nulls does not meet the accuracy requirements of today's direction finding systems (Figure 2-4).

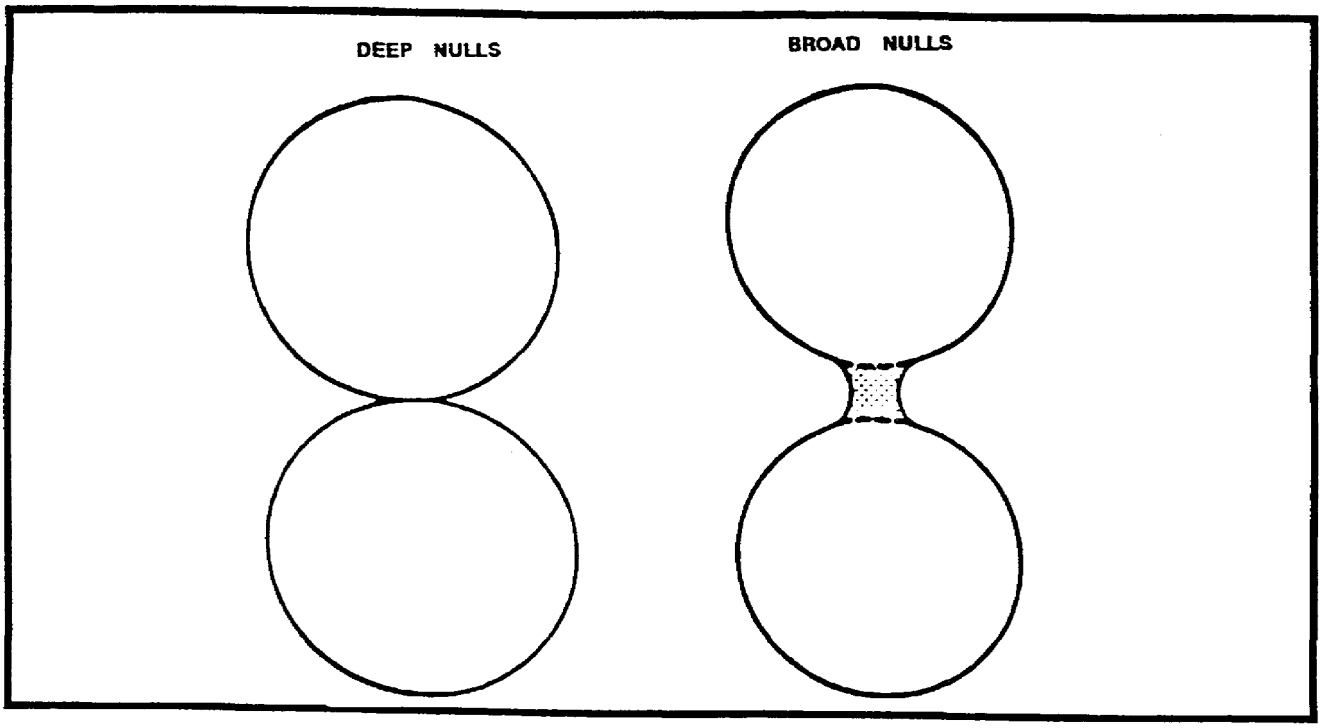

Figure 2-4. Deep nulls and broad nulls.

PART C: REQUIREMENTS

1. The principal antennas used in direction finding are the loop (Figure 2-5), crossed loop (Figure 2-6), Adcock (Figure 2-7), crossed Adcock (Figure 2-8), and circularly disposed antenna arrays (CDAA, Figure 2-9). Each has directional properties, and can be used with direction finding sets to meet specific requirements. Your studies in wave propagation, and definitions of terms used in antenna theory should have given you the terms you will need to understand the following discussion.

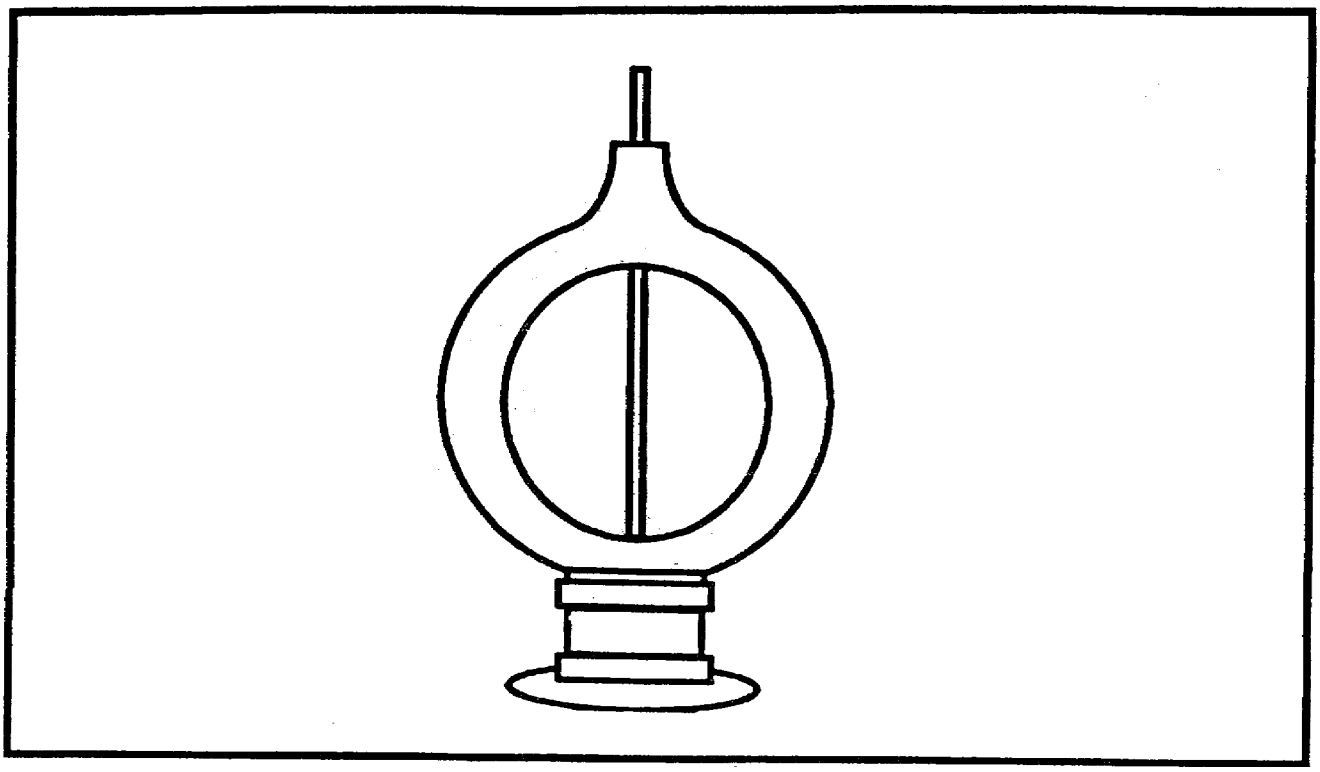

Figure 2-5. Loop Antenna.

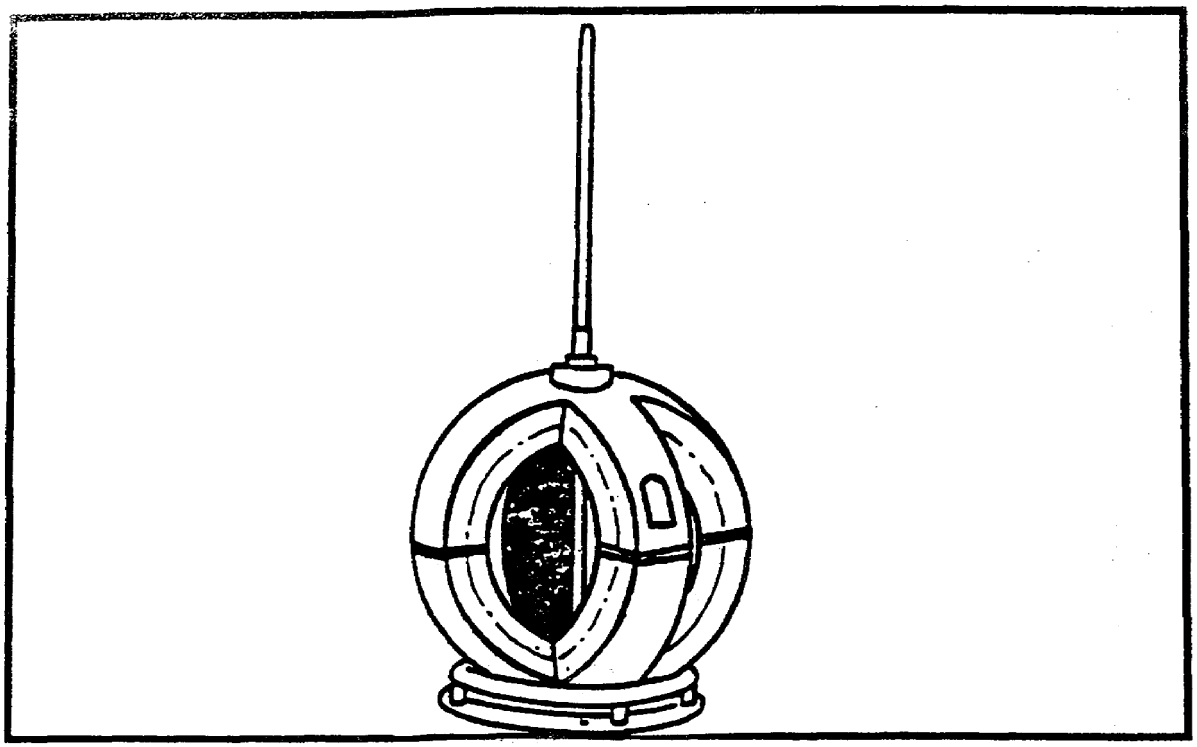

Figure 2-6. Crossed loop antenna.

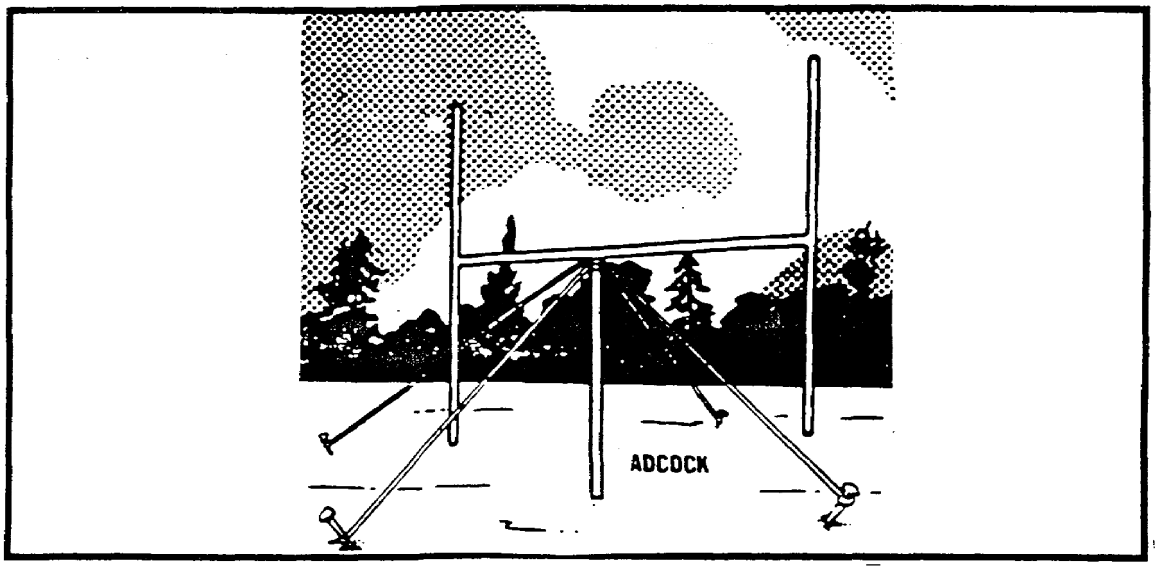

Figure 2-7. Adcock antenna.

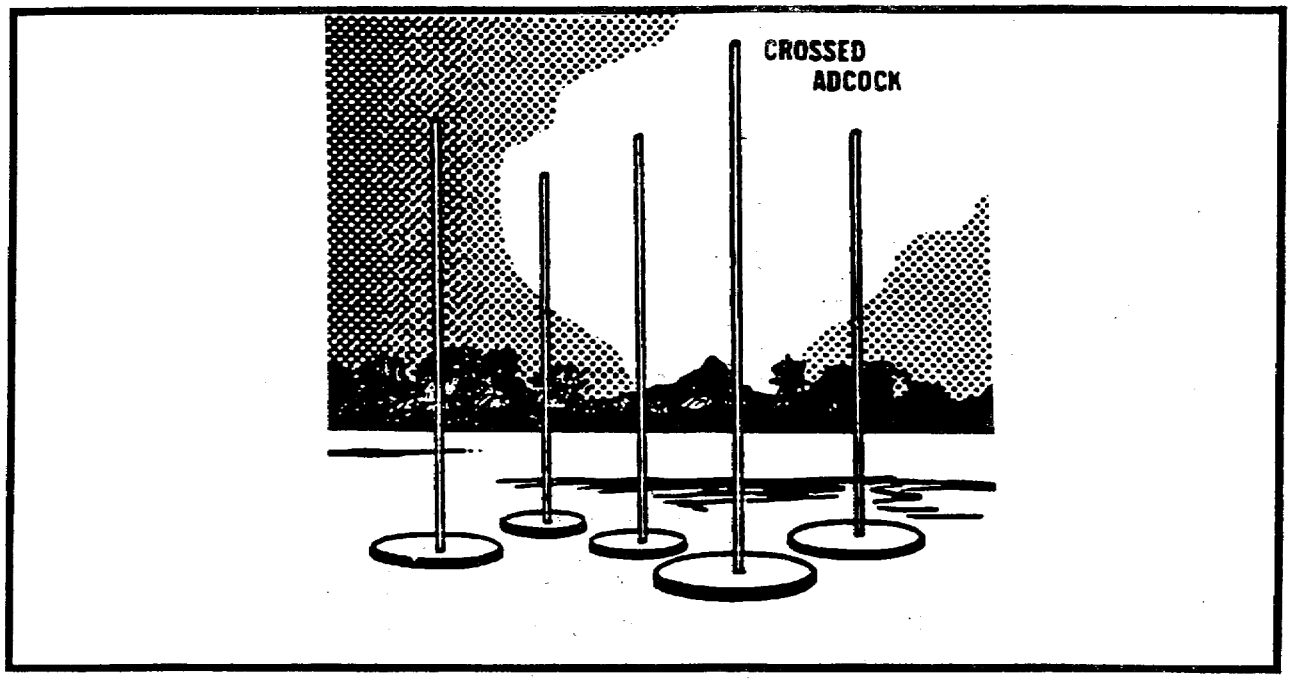

Figure 2-8. Crossed adcock antenna.

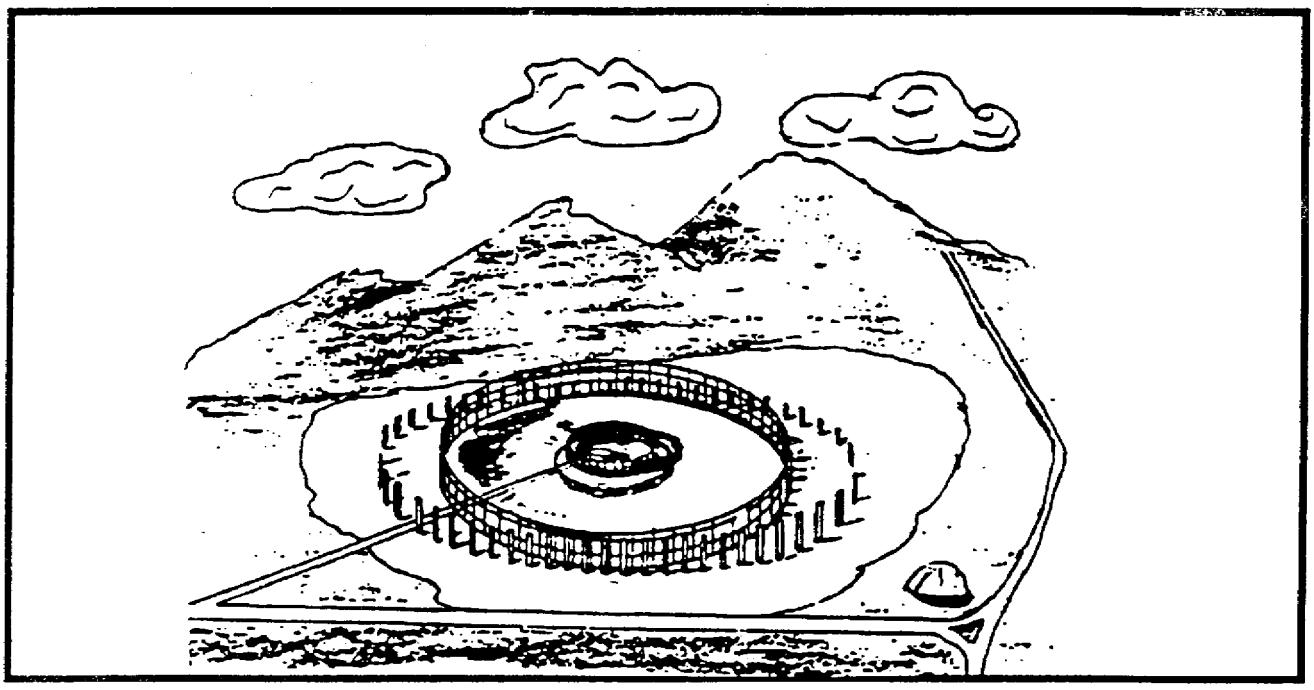

Figure 2-9. Circularly disposed antenna array.

Loop antennas are as old as radio itself. Hertz used them in the original experiments demonstrating transmission and reception, and their directional properties were known long

before there were enough transmitters to make direction finding worthwhile, A loop antenna consists of one or more turns of conductor, either self supporting or wound on a frame. The most common are diamond, square or circular loops (Figure 2-10).

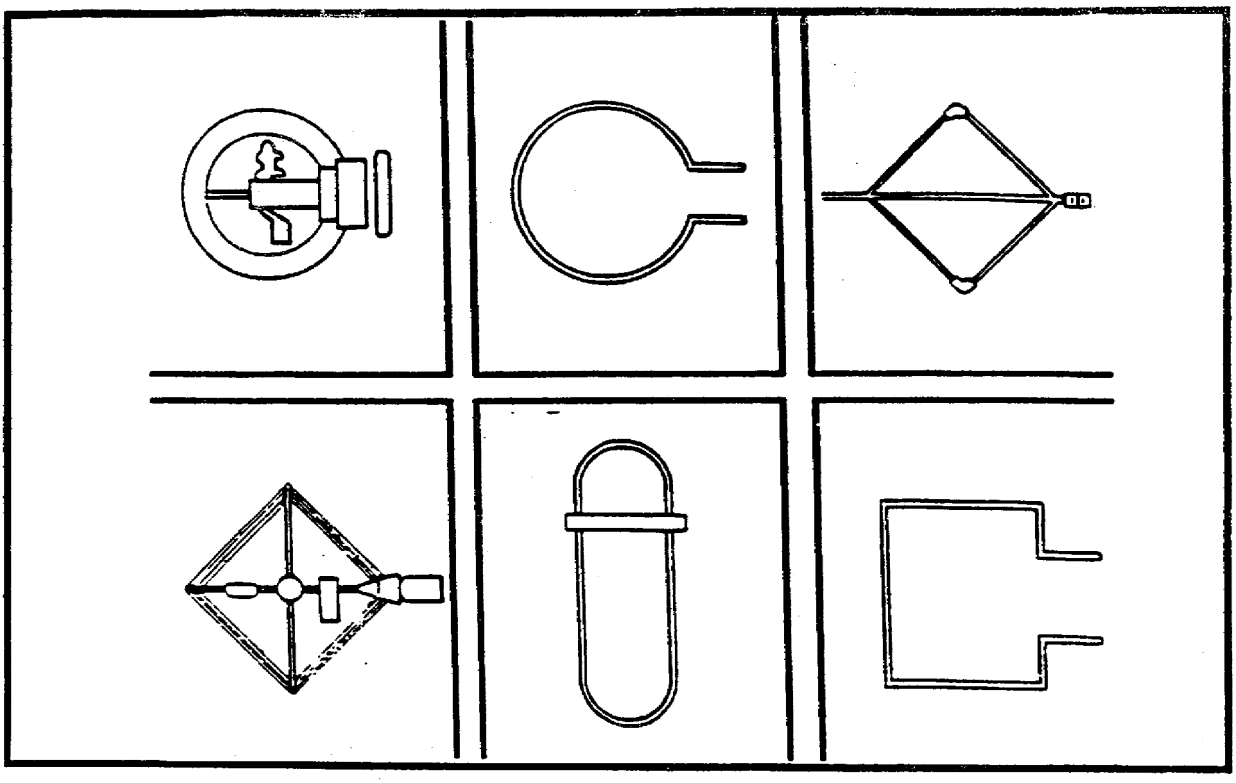

Figure 2-10. Variation of Loop Antennas.

Imagine a loop placed in the path of a vertically polarized wave and turned so that a line from side to side of the loop is parallel (plane perpendicular to the wave front) to the direction of the wave. (Refer to Figure 2-3). Since polarization is discussed in terms of the electric field, the magnetic field of a vertically polarized wave is horizontal. This horizontal magnetic field induces voltage in the loop's vertical arms and in the horizontal arms, since the wave travels parallel to them. The two voltages induced into the vertical arms tend to partially cancel across the antenna, but only partially, since the simultaneous voltages are different. This causes a voltage according to the size of the wave, or put more technically, a voltage is developed which has a magnitude relative to the field intensity of the wave. If the loop is rotated until it is broadside (plane parallel to the wave front) to the oncoming wave the voltages induced in the arms are equal and in phase with each other and cancel across the coupler to give a minimum response, or null. Two null points are present in a loop, 180 degrees apart, giving the antenna a response pattern shaped like a figure eight. (See Figure 2-11).

Unless the general direction of the transmitter is known, a direction finder equipped with a single loop cannot determine whether the transmitter lies forward or to the rear of the direction finder. There is no indication as to which of the two nulls indicates the true direction. From the previous lesson you may remember that this is known as the BIDIRECTIONAL AMBIGUITY, and solving the problem is known as resolving the bidirectional ambiguity. A sense antenna,

usually a whip, is placed at the center axis of the loop, and the two response patterns are electrically combined to produce an unbalanced pattern (cardioid, or heart-shaped) which can be used to resolve the bidirectional ambiguity.

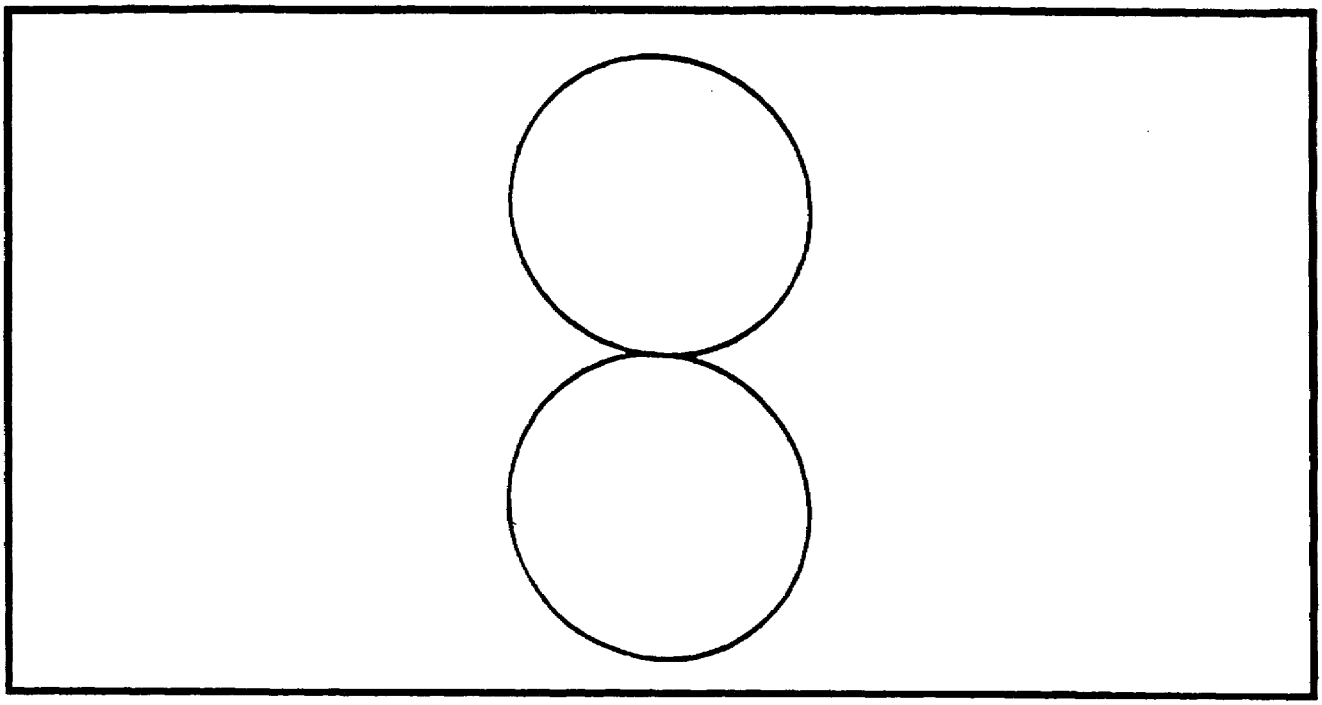

Figure 2-11. Two null points.

The crossed loop antenna consists of two loops with identical characteristics mounted at right angles to each other. Each loop has a figure eight pattern, but the two patterns are displaced 90 degrees in azimuth. As a result, the ratio of the two responses varies with direction. The outputs of the two antennas are connected through a coupler which can be rotated to find the null. This coupler is called a goniometer or a rotary coupler. Since the loops themselves are not rotated they can be made quite large for increased sensitivity. Loop and crossed loop antennas are subject to large polarization errors.

An adcock antenna consists of two spaced vertical antennas connected in opposition (one to each side of a coil). An example of a common type of Adcock is shown in Figure 2-12. In theory it responds only to the vertically polarized wave and, therefore, is not subject to polarization error. In practice there is some polarization error, but usually much less than In a loop receiving the same signal. The Adcock is preferable when medium or high frequency signals must be received at a point beyond ground wave range.

The action of the antenna, as far as vertically polarized waves are concerned, is identical with that of the loop. A resultant current in the output coil is proportional to the difference of the voltages induced in the vertical members, exactly as in the loop. Horizontally polarized components of the incoming signals do not affect the antenna because of the absence of upper and lower horizontal members and because the crossed arrangement of the center

members effectively cancels the voltage induced in them. The response pattern is the same figure eight as the loop antenna.

Both the loop and Adcock antenna have polarization errors when the incoming wave is horizontally polarized, but so long as the vertical polarization is predominant the Adcock is

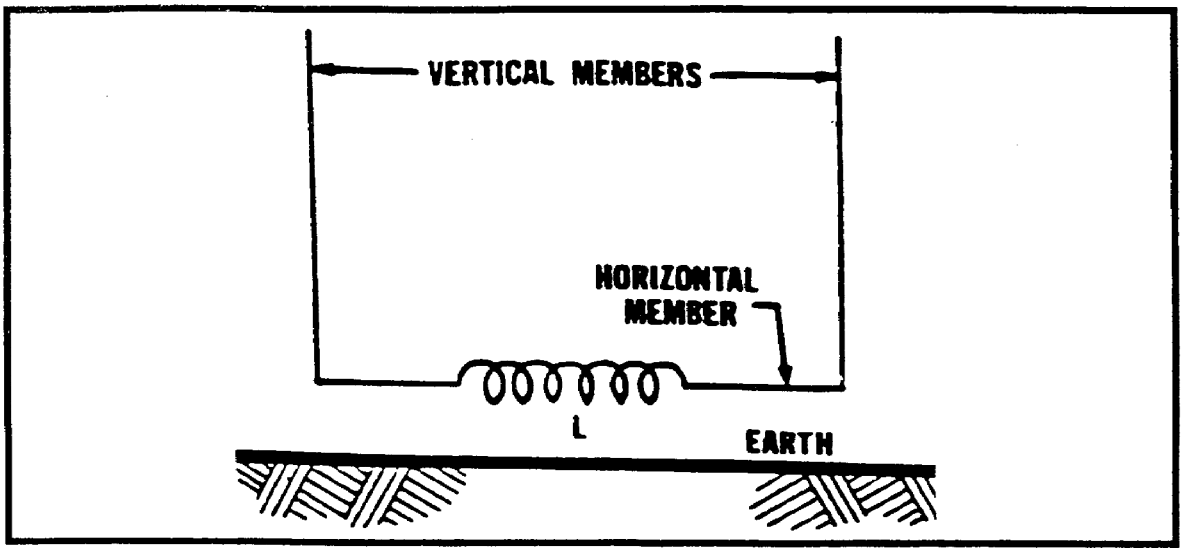

Figure 2-12. Example of adcock antenna.

relatively free from polarization error. The Adcock antenna also requires a sense antenna to resolve the bidirectional ambiguity.

The crossed Adcock antenna consists of two identical Adcock antennas oriented 90 degrees apart in azimuth. At low or medium frequencies crossed Adcock antennas can be made much larger than rotatable Adcocks and are, therefore, much more sensitive. At high frequencies this advantage is small because of the limitations imposed by spacing (OCTANTAL ERROR).

In a crossed Adcock system the maximum spacing is 1/2 wavelength between antennas (.707 wave length between diagonally spaced antennas). Above this limit the same indication may be obtained for signals coming from three different directions. (Six before sensing). Above approximately half this absolute limit the correction of octantal errors is necessary for almost every azimuth reading taken, and the nominal top frequency is usually set at this point.

Circularly disposed antenna arrays (CDAA) are the largest installations sometimes several areas in size requiring special coupling and sensing devices in order to present a directional pattern on a visual display system. (Refer to Figure 2-9) While the systems are both accurate and sensitive, direction finding is not their primary purpose.

Interferometric systems are a completely different class of direction finding systems (as illustrated in Figure 2-13). The azimuth of an incoming wave is not deduced by rotating beams. It is taken from the phase measurements of signals, made on a number of spaced antennas. Unlike the beam-forming type of WADFs, interferometers accept all signals on the

array. Two different approaches are used to process the results. Depending on the type of system, one or both of the following may be used:

- Wavefront analysis (WFA).
- Wavefront testing (WFT).

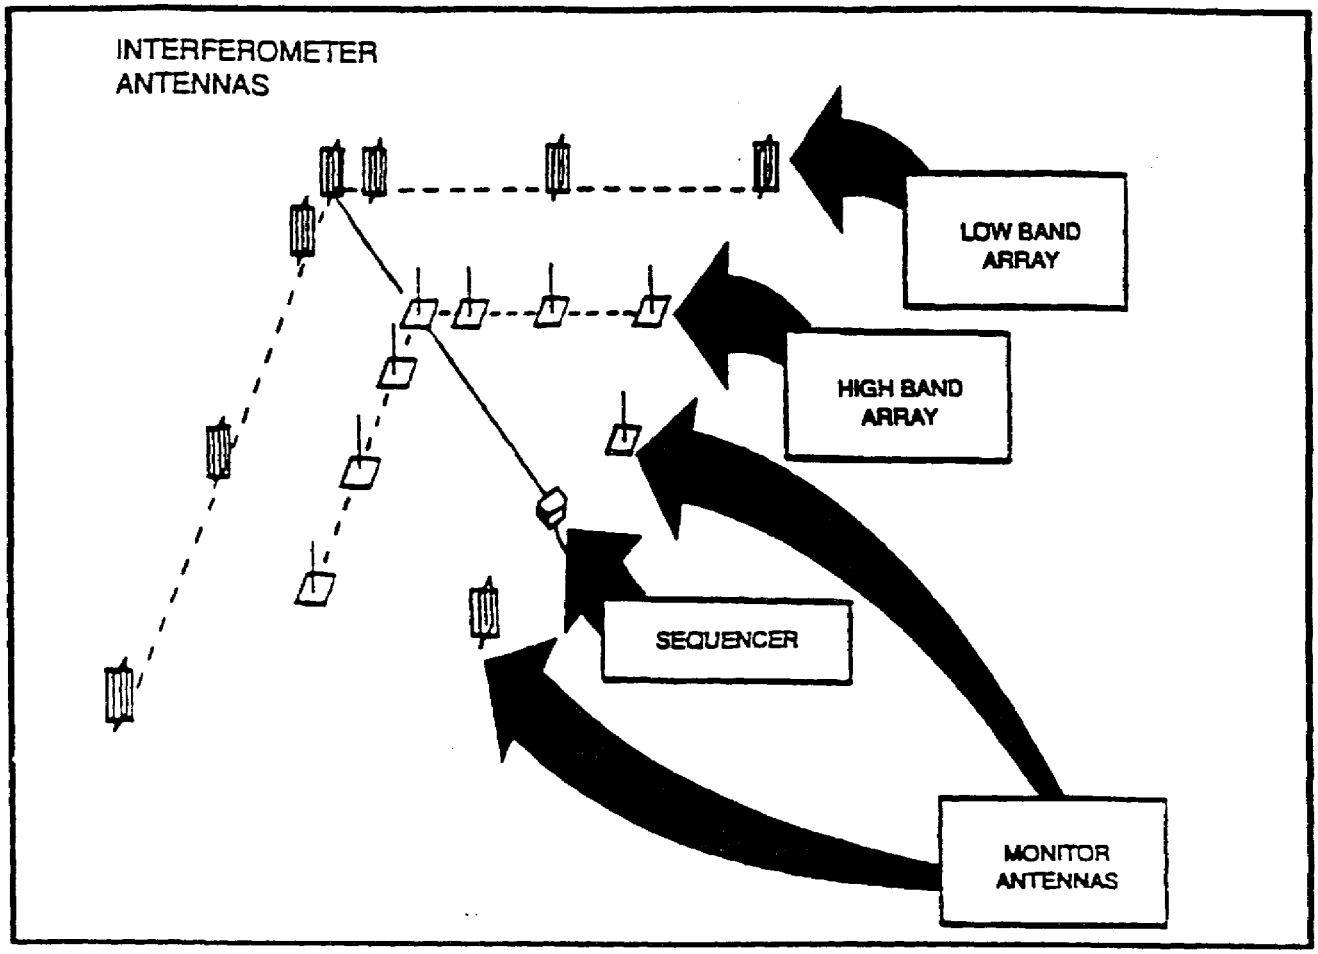

Figure 2-13. Interferometric system.

Wavefront analysis accepts all signals but attempts to recover the major ones. it attempts this by analyzing the complex voltages measured on the elements of the antenna array under wave Interference conditions.

Wavefront testing accepts only signals arriving from one direction or quasi uni-modal propagation (QUMP). QUMP is achieved by detecting a linear phase shift across the array with near equal amplitudes on all the elements. (This process is also called coincidence interferometry.)

The requirements for an efficient coupling system for DF are simple, and there are several types in use, some more complex than others, but all categorized into two groups;

(1) Systems used with fixed antennas.

(2) Systems used with rotatable antennas.

The requirements for coupling systems are:

(1) The system must efficiently conduct the energy picked up by the antenna to the radio. If this requirement is not met the direction finder will lack sensitivity.

(2) It must not pick up or otherwise add additional energy from the wanted signal. Failure to meet this requirement results in bearing errors.

(3) It must not introduce unwanted signals or noise. These effects, if present, produce interference and impair the bearing readability.

With rotatable antennas the two most common types of coupling are DIRECT, and TRANSMISSION LINE.

Direct coupling is the simplest form of coupling, directly coupling the antenna terminals to the receiver input. It is used in those few cases where it is practicable to design a DF system in which the radio receiver is located at the antenna terminals, and the antenna and receiver rotate together as a unit. Some directly coupled DF sets are small, hand-carried, transistorized receiving sets used by counterinsurgency personnel. The loop is generally the carrying handle, and the entire set is rotated to produce line bearings in the direction of the target transmitter.

Transmission line coupling is used in its simplest form when the antenna system is placed some distance above, but is rotatable with, the DF receiver. Because of its length and position the transmission line will, if its shielding or balance are not perfect, introduce unwanted energy, causing bearing errors or impaired readability. Additionally, if the length of the transmission line is an appreciable fraction of a wavelength or more, its characteristic impedance must accurately match the impedance of the receiver and the antenna, or a considerable loss of sensitivity will occur.

The direct and transmission line systems of coupling the antenna to the receiver may be used when it is desired to rotate the antenna without rotating the receiver. This is accomplished by adding a rotatable coupling element. Some of these elements are:

(1) Slip rings. These are insulated metal rings in contact with sliding fingers or brushes, which permit rotation without interrupting the circuit. By mounting the rings on a shaft and providing fixed brushes, it is possible to conduct the antenna current to a stationary receiver while permitting the antenna to turn at will.

(2) Rotating transformer. This rotatable coupling device consists of a transformer whose primary and secondary windings are coaxial. Under this condition one winding may be rotated with respect to the other without changing the coupling which exists between them.

(3) Rotating capacitator. This element makes use of the fact that the capacitance between coaxial rings or discs is independent of their rotation.

Fixed antennas use some form of goniometer. The term goniometer is applied to a device used to couple two or more input circuits (usually connected to antennas) to an output circuit (usually connected to the receiver). This is done in such a manner that the degree of coupling varies with the rotation of a shaft. The coupling between one input circuit and the output circuit decreases while the coupling with the other input circuit increases. When properly connected, a well constructed goniometer provides an output at each position of its shaft identical to that which would be produced by a single figure-eight pattern antenna oriented to the corresponding position. Thus, the goniometer provides an equivalent for the rotation of an antenna, and makes it possible to use large fixed antenna systems (either loop, Adcock, CDAA, or others) which would be too bulky for an operator to rotate.

Goniometers must meet these basic requirements:

(1) The fixed elements must be electrically identical.

(2) There must be a complete absence of coupling between the fixed elements.

(3) Accurate positioning of the fixed elements at the same angle as the antennas (usually 90 degrees) is necessary.

(4) Coupling between the rotating element and the fixed elements must vary with shaft revolution in the same manner as the variation of antenna response with azimuth angle. These requirements are met in practical goniometers to the extent that the maximum error is less than plus or minus one degree.

In applying to the goniometer to a practical direction finder, it is often desirable to locate the goniometer some distance away from the antenna. To accomplish this, it is necessary to provide transmission lines between the antenna and its goniometer. These lines must be well shielded and are usually balanced to ground to avoid stray pick-up. Additionally, the transmission lines connecting the several antennas to the goniometer must be electrically identical, particularly in time delay, over the entire frequency range of the equipment in order to preserve accuracy and provide deep nulls.

The principal types of goniometers are:

(1) Inductive, usually consisting of two fixed windings at right angles to each other and enclosing a third winding which rotates on a shaft.

(2) Capacitive, with two fixed sets of plates enclosing a rotatable set of plates, and

(3) Electronic, which utilizes circuitry instead of physical rotation, and, therefore, allows higher speeds than can be obtained by mechanical rotation.

The use of a goniometer introduces an additional possibility for octantal error above that caused by antenna spacing. This is caused by nonuniformity within the electric fields of the stationary windings of the goniometer. In early days this nonuniformity was considerable, and octanta! error was large. In more modern goniometers, the windings are distributed in such a manner that this cause of octantal error is practically eliminated. The octantal error is

caused by antenna spacing still exists, usually requiring a correction chart for the higher ranges o the equipment.

2. The type of bearing **indicator** used with any particular direction finder depends on the type of DF system in use, the complexity and physical size permitted, and the accuracy desired for a particular DF application. Many types of bearing indicators have been designed and used in DF systems, but those having the greatest application can be grouped into the categories of AURAL indicators and VISUAL indicators. Visual indicators can be further grouped into three subelements, left-right indicators, instantaneous indicators, and automatic bearing seeking indicators. Each type of indicator has certain specific characteristics and applications. Many of these characteristics are closely related to, and cannot be separated from, characteristics of the type of DF system with which a particular indicator is used. Therefore, keep in mind that some of the characteristics credited to a specific indicator are really characteristics of the DF system with which the indicator is used.

Aural Indicators. An aural indicator is a headset or loudspeaker connected to the DF receiver audio circuit. It enables the operator to detect the bearing of a signal by changes in audible receiver output as the antenna is rotated. In DF systems which use aural indicators, the antenna system must be able to be rotated to the bearing position, and this position must be characterized by an abrupt change in the antenna response pattern, and, therefore, in the receiver output.

In most common direction finders which use an aural indication the antenna is a rotatable loop or Adcock, or a fixed crossed-loop or crossed-Adcock effectively rotated by a goniometer. All these antennas have, or result in, a figure-eight response pattern with broad maxima and sharp nulls. Therefore, the nulls of the system are selected as the bearing points. Because of this, these systems are called aural-null indicators. At higher frequencies (several hundred megahertz) directional arrays having response patterns with sharp maxima can be used. Because aural-null systems are more common we will not discuss aural-maxima systems further.

The most important characteristics of an aural-null indicator are:

(1) It is the simplest indicator that can be used with a direction finder for the following reasons;

(a) it adds nothing to the direction finder because a headset or loudspeaker is usually included for monitoring purposes.

(b) it can be used with simple loop or Adcock antenna systems without the addition of complicated couplings.

(c) it reduces to a minimum the size, weight, and maintenance factors of the indicator.

(d) it is simple to use, even by unskilled operators.

(2) Because it does not necessitate the use of complicated and elaborate antenna, coupler, and receiving systems, the sensitivity and instrumental accuracy of the direction finder is high.

(3) The indicator cannot detract from the accuracy inherent in the remainder of the system.

(4) The readability of the indicator is not influenced by the type of signal received, whether it is continuous wave (cw), interrupted continuous wave (icw, or modulated continuous wave (mcw). Readability shows how the indicator can detect relatively small changes.

(5) The readability of the indicator is high on weak signals in the presence of noise or interference signals because the human ear can distinguish between desired and undesired signals.

(6) The readability is poor on fading signals because it cannot discriminate between a fade and a null indication.

(7) The readability of the indicator is poor on swinging signals because the antenna cannot be rotated fast enough to follow the swinging bearing. A swinging signal is one that because of propagation errors seems to move back and forth through several degrees of arc.

(8) An extra operation must be performed to determine which of the two directions indicates the correct azimuth (sensing).

3. Visual indicators. Visual indication has been accomplished through various means. Each has the common characteristic of operation by comparison of antenna voltages. These voltages may originate from any of several antennas. Among the types of visual indication are left-right meter, crossed pointer meter, magic eye, matched line oscilloscopes, and instantaneous oscilloscope indicators. Because the instantaneous indicators are most common this lesson will limit itself to them.

An instantaneous indicator, using a cathode ray tube, continuously and automatically presents on the tube screen a pattern or trace that points toward the azimuth of the arriving signal as read from an azimuth scale situated around the tube face. The presentation of this pattern is accomplished without manually rotating the DF antenna to the bearing point.

The antenna system must be one of the following types:

(a) It may be a fixed oriented, crossed loop or crossed Adcock variety and effectively rotated through 360 degrees at some continuous and constant rate by a spinning mechanical goniometer or electric goniometer method.

(b) The antenna system may be a single-loop or Adcock that is continuously rotated by mechanical means at a constant rate through 360 degrees.

(c) The antenna system may be of the fixed oriented, crossed loop or crossed Adcock variety and the output of each of the antennas must be maintained as separate signals through individual channels in the indicator.

(d) The antenna may be of the CDAA type and employ either antenna switching or goniometers to effectively rotate the antenna through 360 degrees at a constant rate.

Because these special features must be incorporated in a DF system using instantaneous indicator, its size, weight, power consumption, complexity of design, and maintenance are greater than for other systems. When not prohibitive, these disadvantages are more than compensated for by the increased performance obtained when using this type of indicator. Characteristics of instantaneous indicators in comparison with aural-null are as follows:

(a) There is greater speed in obtaining bearings because the antenna is usually not rotated.

(b) Simplicity of operation is increased. Tuning the receiver and reading the bearing are the only operations necessary.

(c) Readability is increased on moderate and weak signals.

(d) There is equal readability on cw, icw, and mcw signals.

(e) Readability on swinging signals is increased because the indication continuously and instantaneously changes with the bearing swing, thus enabling the operator to choose the most likely bearing.

(f) Readability on fading bearings is increased because the indicator has a high degree of discrimination between a change in signal level due to fade, and a change in bearing and signal indication.

(g) There is increased readability on combinations of swining, fading and unfavorably polarized signals, because the indicator exhibits certain features which tell the operator when conditions are most favorable for obtaining a bearing.

(h) Sense indication may be simultaneous with the presentation (continuously sensed) or it may be accomplished by pressing a key (sense switch).

(i) Readability in the presence of interfering signals is fair, although not as good as with aural indication.

4. Bearing seeking indicators. Bearing seeking indicators are normally used on aircraft where an automatic bearing readout is required but size and weight requirements preclude the use of Instantaneous visual indication. In these systems the antenna system is rotated automatically to the true bearing position and a pointer on the indicator comes to rest when it is aligned with the antenna.

LESSON 2

PRACTICE EXERCISE

The following items will test your grasp of the material covered in this lesson. There is only one correct answer for each item. When you have completed the exercise, check your answers with the answer key that follows. If you answer any item incorrectly, study again that part of the lesson which contains the portion involved.

1. Including a receiver, what are the other basic equipment requirements needed for a DF system?

   A. Aural Null, Visual Indicator, and a Coupler
   B. Aural Null, Visual Indicator, and a Directional Antenna
   C. Coupler, Indicator, and a Directional Antenna
   D. Coupler, Indicator, and a Secondary Receiver

2. Besides stability and selectivity, what else must a DF receiver have?

   A. BFO, and Headsets
   B. BFO, and Sensitivity
   C. Sensitivity, and Headsets
   D. Sensitivity, and Frequency Range

3. What device connects the antenna to the receiver?

   A. Coupling
   B. Goniometer
   C. Frequency Modulator
   D. Antenna Modulator

4. What is an example of a visual indicator for the null?

   A. Goniometer
   B. Crossed Pointer
   C. Loudspeaker
   D. Cathode Ray Tube

5. DF equipment comes in several sizes. What are the specific requirements dictated by?

   A. The Mission
   B. The Cost
   C. The Location
   D. Transportation Capabilities

6. What part of the DF receiver is used to give a steady tone for ease of direction finding/AM signals?

   A. Aural Null
   B. BFO
   C. AM Modulator
   D. FM Modulator

7. What device is used to electrically rotate an antenna?

   A. Slip Rings and Brushes
   B. Goniometer
   C. Direct Coupling
   D. Cathode Ray Tube

8. Which is the simplest form of coupling?

   A. Transmission line
   B. Rotating
   C. Direct
   D. Indirect

9. Which antenna requires an additional sense antenna?

   A. Loop
   B. Adcock
   C. Both Loop and Adcock
   D. Neither Loop no Adcock

10. What is the most common type of visual indicator?

    A. Left-Right Meter
    B. Crossed Pointer Meter
    C. Oscilloscope Indicator
    D. Instantaneous Indicator

Preface

This manual is a reference text for trainees and other personnel in the communications-electronics field. It provides information about wave propagation, transmission lines, and antennas. This manual also identifies important safety practices to follow when working with electromagnetic radiation.

The proponent of this publication is Headquarters, U.S. Army Training and Doctrine Command (TRADOC). Send comments and recommendations for improving this document on DA Form 2028 (*Recommended Changes to Publications and Blank Forms*) directly to: Commander, USACASCOM&FL, Training Directorate, Ordnance Training Division, ATTN: ATCL-AO, 401 First Street, Fort Lee, Virginia 23801.

Unless this publication states otherwise, masculine nouns and pronouns do not refer exclusively to men.

Chapter 1

Wave Propagation

The methods used to propagate (transmit) waves through space are based on the same physical principles today as they were 70 years ago. In this chapter, we discuss propagation theory on an introductory level, without going into the technical details that concern the engineer. Understanding wave propagation requires you to use your imagination to visualize the associated concepts and how they are used in practical application. To help you in this process, this chapter includes many illustrations and step-by-step descriptions that guide you from simple concepts to more complex ideas. This chapter covers the fundamentals of wave propagation and the physical factors that affect propagation. Many of the principles discussed are observable in common, everyday occurrences with which you are already familiar.

LEARNING OBJECTIVES

1-1. Learning objectives are included at the beginning of each chapter and serve as a preview of the information you are expected to learn. Comprehensive check questions are included at the end of the chapters and are based on the learning objectives. Upon completing this chapter, you should be able to do the following:

- State what wave motion is; define the terms reflection, refraction, and diffraction; and describe the Doppler effect.
- State what sound waves are and define a propagating medium.
- List and define terms as applied to sound waves, such as cycle, frequency, wavelength, and velocity.
- List the three requirements for sound.
- Define pitch, intensity, loudness, and quality and their application to sound waves.
- State the acoustical effects that echoes, reverberation, resonance, and noise have on sound waves.
- Define light waves and list their characteristics.
- List the various colors of light and define the terms reflection, refraction, diffusion, and absorption as applied to light waves.
- State the difference between sound waves and light waves.
- State the electromagnetic wave theory and list the components of the electromagnetic wave.

WHAT IS PROPAGATION?

1-2. Early man was quick to recognize the need to communicate beyond the range of the human voice. To satisfy this need, he developed alternate methods of communication, such as hand gestures, beating on a hollow log, and smoke signals. Although these methods were effective, they were still greatly limited in range. Eventually, the range limitations were overcome by the development of courier and postal systems; but there was then a problem of speed. For centuries the time required to deliver a message depended on the speed of a horse.

1-3. During the latter part of the nineteenth century, both distance and time limitations were largely overcome. The invention of the telegraph made possible instantaneous communication over long wires. Then a short time later, man discovered how to transmit messages in the form of radio waves.

1-4. As you will learn in this chapter, radio waves are propagated. Propagation means "movement through a medium." Light rays most easily illustrate this concept. When a light is turned on in a darkened room, light rays travel from the light bulb throughout the room. When a flashlight is turned on, light rays also radiate from its bulb, but are focused into a narrow beam. You can use these examples to picture how radio waves propagate. Like the light in the room, radio waves may spread out in all directions. They can also be focused (concentrated) like the flashlight, depending upon the need. Radio waves are a form of radiant energy, similar to light and heat. Although they can neither be seen nor felt, their presence can be detected through the use of sensitive measuring devices. The speed at which both forms of waves travel is the same; they both travel at the speed of light.

1-5. You may wonder why you can see light but not radio waves, which consist of the same form of energy as light. The reason is that you can see only what your eyes can detect. Your eyes can detect radiant energy only within a fixed range of frequencies. Because the frequencies of radio waves are below the frequencies your eyes can detect, you cannot see radio waves.

PRINCIPLES OF WAVE MOTION

1-6. All things on the land, or in the water are showered continually with waves of energy. Some of these waves stimulate our senses and can be seen, felt, or heard. For instance, we can see light, hear sound, and feel heat. However, there are some waves that do not stimulate our senses. For example, radio waves, such as those received by our portable radio or television sets, cannot be seen, heard, or felt. A device must be used to convert radio waves into light (TV pictures) and sound (audio) for us to sense them.

1-7. A wave can be defined as a disturbance (e.g., sound, light, radio waves) that moves through a medium (e.g., air, water, vacuum). To help you understand what is meant by "a disturbance that moves through a medium," picture the following illustration. You are standing in the middle of a wheat field. As the wind blows across the field toward you, you can see the wheat stalks bending and rising as the force of the wind moves into and across them. The wheat appears to be moving toward you, but it isn't. Instead, the stalks are actually moving back and forth. We can then say that the

"medium" in this illustration is the wheat and the "disturbance" is the wind moving the stalks of wheat.

1-8. Wave motion can be defined as a recurring disturbance advancing through space with or without the use of a physical medium. Wave motion, therefore, is a means of moving or transferring energy from one point to another point. For example, when sound waves strike a microphone, sound energy is converted into electrical energy. When light waves strike a phototransistor or radio waves strike an antenna, they are likewise converted into electrical energy. Therefore, sound, light, and radio waves are all forms of energy that are moved by wave motion. We discuss sound waves, light waves, and radio waves later in this chapter.

WAVE MOTION IN WATER

1-9. A type of wave motion familiar to almost everyone is the movement of waves in water. We explain these waves first to help you understand wave motion and the terms used to describe it.

1-10. Basic wave motion can be shown by dropping a stone into a pool of water (see figure 1-1). As the stone enters the water, a surface disturbance is created, resulting in an expanding series of circular waves.

Figure 1-1. Formation of Waves in Water

1-11. Figure 1-2 is a diagram of this action. View A shows the falling stone just an instant before it strikes the water. View B shows the action taking place at the instant the stone strikes the surface, pushing the water that is around it upward and outward. In view C, the stone has sunk deeper into the water, which has closed violently over it causing some spray, while the leading wave has moved outward. An instant later, the stone has sunk out of sight, leaving the water disturbed as shown in view D. Here the leading wave has continued to move outward and is followed by a series of waves gradually diminishing in amplitude. Meanwhile, the disturbance at the original point of contact has gradually subsided.

1-12. In this example, the water is not actually being moved outward by the motion of the waves, but up and down as the waves move outward. The up and down motion is transverse, or at right angles, to the outward motion of the waves. This type of wave motion is called transverse wave motion.

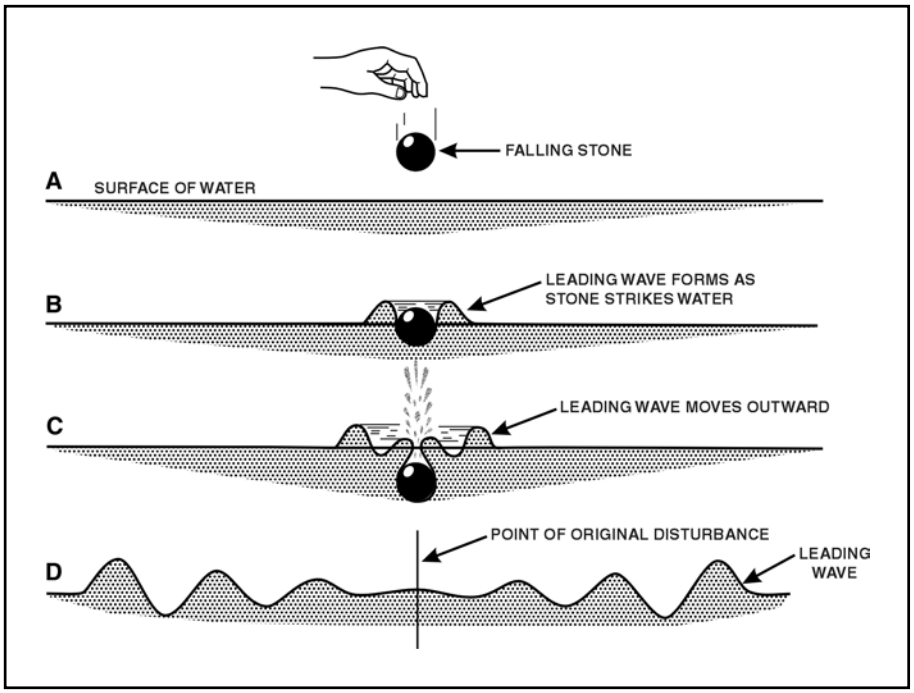

Figure 1-2. How a Falling Stone Creates Wave Motion on Water's Surface

TRANSVERSE WAVES

1-13. To explain transverse waves, we again use our example of water waves. Figure 1-3 is a cross-section diagram of waves viewed from the side. Notice that the waves are a succession of crests and troughs. The wavelength (one 360-degree cycle) is the distance from the crest of one wave to the crest of the next, or between any two similar points on adjacent waves. The amplitude of a transverse wave is half the distance measured vertically from the crest to the trough. Water waves are known as transverse waves because the motion of the water is up and down, or at right angles to the direction in which the waves are traveling. You can see this by observing a cork bobbing up and down on water as the waves pass by; the cork moves very little in a sideways direction.

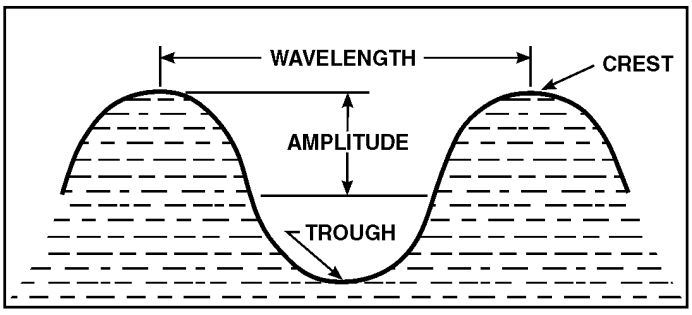

Figure 1-3. Elements of a Wave

1-14. In figure 1-4, the small arrows show the up-and-down direction the cork moves as the transverse wave is set in motion. The large arrow shows the direction the wave travels. Radio waves, light waves, and heat waves are examples of transverse waves.

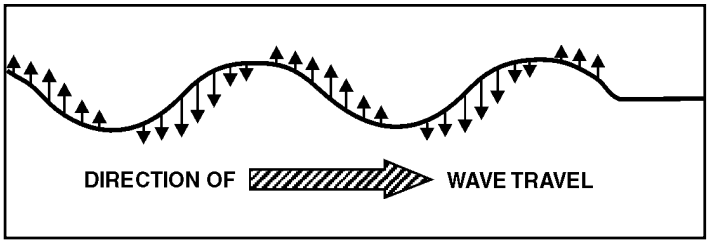

Figure 1-4. Transverse Wave

LONGITUDINAL WAVES

1-15. In the previous discussion, we listed radio waves, light waves, and heat waves as examples of transverse waves, but we did not mention sound waves. Why? Simply because sound waves are longitudinal waves. Unlike transverse waves, which travel at right angles to the direction of propagation, sound waves travel back and forth in the same direction as the wave motion. Therefore, longitudinal waves are waves in which the disturbance takes place in the direction of propagation. Longitudinal waves are sometimes called compression waves.

1-16. Waves that make up sound, such as those set up in the air by a vibrating tuning fork, are longitudinal waves. When struck, the tuning fork in figure 1-5 sets up vibrations. As the tine moves in an outward direction, the air immediately in front of it is compressed (made more dense) so that its momentary pressure is raised above that at other points in the surrounding medium (air). Because air is elastic, the disturbance is transmitted in an outward direction as a compression wave. When the tine returns and moves in the inward direction, the air in front of the tine is rarefied (made less dense or expanded) so that its pressure is lowered below that of the other points in the surrounding air. The rarefied wave is propagated from the tuning fork and follows the compressed wave through the medium (air).

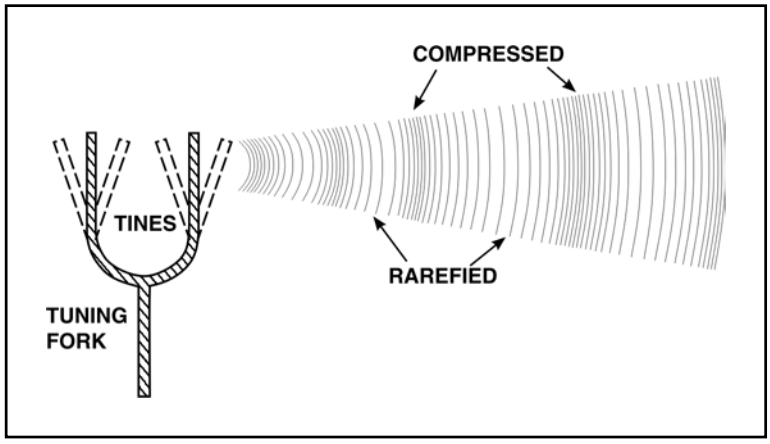

Figure 1-5. Sound Propagation by a Tuning Fork

MEDIUM

1-17. We have used the term medium in describing the motion of waves. Because medium is a term that is used frequently in discussing propagation, it needs to be defined so you will understand what a medium is and its application to propagation.

1-18. A medium is the vehicle through which the wave travels from one point to the next. The vehicle that carries a wave can be just about anything. An example of a medium, already mentioned, is air. Air, as defined by the dictionary, is the mixture of invisible, odorless, tasteless gases that surrounds the earth (the atmosphere). Air is made up of molecules of various gases (and impurities). We will call these molecules of air particles of air or simply particles. Figure 1-6 can help you to understand how waves travel through air. The object producing the waves is called the source—a bell in this illustration. The object responding to the waves is called a detector or receiver; in this case, the human ear. The medium is air, which is the means of conveying the waves from the source to the detector. The source, detector, and medium are all necessary for wave motion and wave propagation (except for electromagnetic waves, which require no medium). The waves shown in figure 1-6 are sound waves. As the bell is rung, the particles of air around the bell are compressed and then expanded. This compression and expansion of particles of air set up a wave motion in the air. As the waves are produced, they carry energy from particle to particle through the medium (air) to the detector (ear).

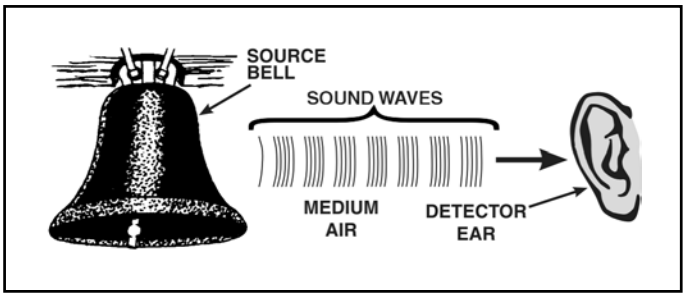

Figure 1-6. The Three Elements of Sound

TERMS USED IN WAVE MOTION

1-19. There are a number of special terms concerning waves that you should know. Many of the terms, such as cycle, wavelength, amplitude, and frequency, were introduced in TC 9-60. We now discuss these terms in detail as they pertain to wave propagation. Before we begin our discussion, however, note that in figure 1-7, wave 1 and wave 2 have equal frequency and wavelength but different amplitudes. The reference line (also known as rest position or point of zero displacement) is the position that a particle of matter would have if it were not disturbed by wave motion. For example, in the case of the water wave, the reference line is the level of the water when no wave motion is present. With this in mind, let us go on to our discussion of the four terms, as shown in figure 1-7.

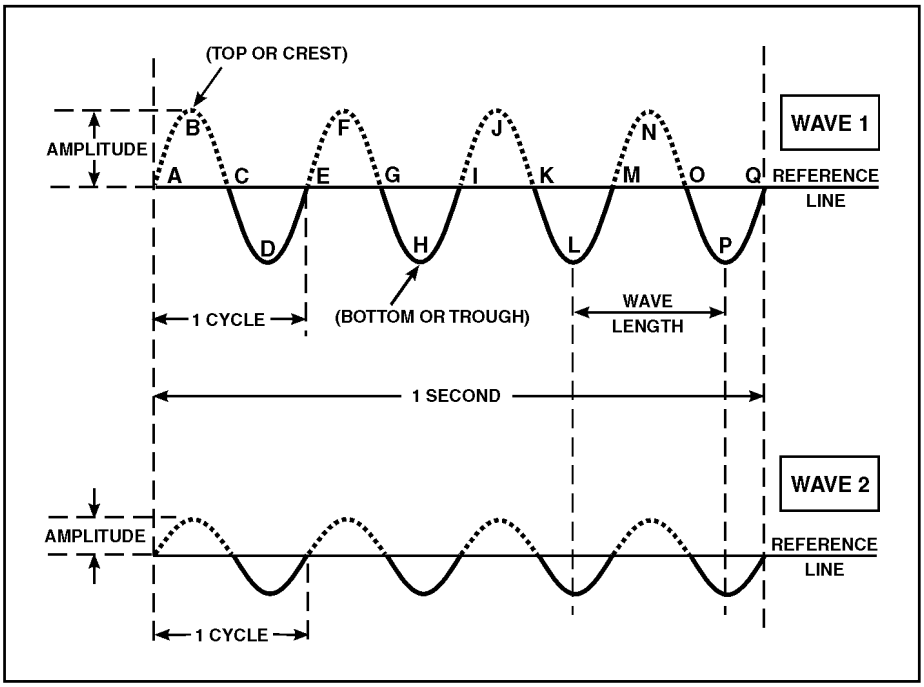

Figure 1-7. Comparison of Waves with Different Amplitudes

Wave Cycles

1-20. Refer to wave 1 in figure 1-7. Notice how similar it is to the sine wave you have already studied. All transverse waves appear as sine waves when viewed from the side. In figure 1-7, wave 1 has four complete wave cycles. Points ABCDE comprise one complete cycle having a maximum value above and a maximum value below the reference line. The portion above the reference line (between points A and C) is called a positive alternation and the portion below the reference line (between points C and E) is known as a negative alternation. The combination of one complete positive and one complete negative alternation represents one cycle of the wave. At point E, the wave begins to repeat itself with a second cycle completed at point I, a third at point M, and so forth. The peak of the positive alternation (maximum value above the line) is sometimes referred to as the top or crest, and the peak of the negative alternation (maximum value below the line) is sometimes called the bottom or trough, as depicted in the figure. Therefore, one cycle has one crest and one trough.

Wavelength

1-21. A wavelength is the distance in space occupied by one cycle of a radio wave at any given instant. If the wave could be frozen in place and measured, the wavelength would be the distance from the leading edge of one cycle to the corresponding point on the next cycle. Wavelengths vary from a few hundredths of an inch at extremely high frequencies to many miles at extremely low frequencies; however, common practice is to express wavelengths in meters. In figure 1-7 (wave 1), the distance between A and E, or B and F, etc., is one wavelength. The Greek letter lambda (λ) is used to signify wavelength. Why lambda and not "l" or "L"? This is because "L" is

used conventionally as the symbol for inductance, and "l" is used for dimensional length; therefore, λ is used to indicate the length of waves.

Amplitude

1-22. Two waves may have the same wavelength, but the crest of one may rise higher above the reference line than the crest of the other. Compare wave 1 and wave 2 of figure 1-7 again. The height of a wave crest above the reference line is called the amplitude of the wave. The amplitude of a wave gives a relative indication of the amount of energy the wave transmits. A continuous series of waves, such as A through Q, having the same amplitude and wavelength, is called a train of waves or wave train.

Frequency and Time

1-23. Time is an important factor in wave studies. When a wave train passes through a medium, a certain number of individual waves pass a given point in a specific unit of time. For example, if a cork on a water wave rises and falls once every second, the wave makes one complete up-and-down vibration every second. The number of vibrations, or cycles, of a wave train in a unit of time is called the frequency of the wave train and is measured in hertz. If 5 waves pass a point in one second, the frequency of the wave train is 5 cycles per second. In figure 1-7, the frequency of both wave 1 and wave 2 is four cycles per second (abbreviated as cps).

1-24. In 1967, in honor of the German physicist Heinrich Hertz, the term hertz was designated for use in lieu of the term "cycle per second" when referring to the frequency of radio waves. It may seem confusing that in one place the term "cycle" is used to designate the positive and negative alternations of a wave, but in another instance the term "hertz" is used to designate what appears to be the same thing. The key is the time factor. The term cycle refers to any sequence of events, such as the positive and negative alternations, comprising one cycle of electrical current. The term hertz refers to the number of occurrences that take place in one second.

CHARACTERISTICS OF WAVE MOTION

1-25. The two types of wave motion, transverse and longitudinal, have many of the same characteristics, such as frequency, amplitude, and wavelength. Another important characteristic that these two types of wave motion share is velocity. Velocity of propagation is the rate at which the disturbance travels through the medium, or the velocity with which the crest of the wave moves along. The velocity of the wave depends both on the type of wave (e.g., light, sound, or radio) and type of medium (e.g., air, water, or metal). If longitudinal waves are plotted as a graph, they appear as transverse waves. This fact is illustrated in figure 1-8. The frequency of a longitudinal wave, like that of a transverse wave, is the number of complete cycles the wave makes during a specific unit of time. The higher the frequency, the greater is the number of compressions and expansions per unit of time.

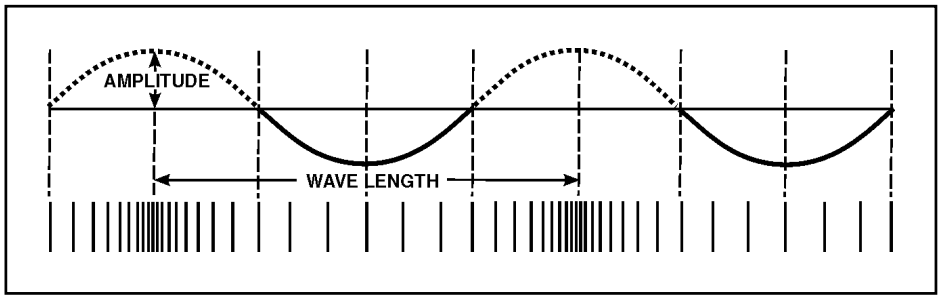

Figure 1-8. Longitudinal Wave Represented Graphically by a Transverse Wave

1-26. In the two types of wave motion described in the preceding discussion, the following quantities are of interest:

- The period, which is the time (T) in which one complete vibratory cycle of events occurs.
- The frequency of vibration (f), which is the number of cycles taking place in one second.
- The wavelength (λ), which is the distance the disturbance travels during one period of vibration.

1-27. Now, consider the following concept. If a vibrating object makes a certain number of vibrations per second, then 1 second divided by the number of vibrations is equal to the period of time of 1 vibration. In other words, the period, or time of 1 vibration is the reciprocal of the frequency. Thus—

$$\text{Time (T) of one vibration} = \frac{1}{\text{frequency (f)}}$$

Or

$$T = \frac{1}{f}$$

1-28. If you know the velocity of a wave, you can determine the wavelength by dividing the velocity by the frequency. As an equation—

$$\lambda = \frac{v}{f}$$

Where:

λ = wavelength
v = velocity of propagation
f = frequency of vibration

1-29. When you use the above equation, be careful to express velocity and wavelength in the proper units of length. For example, in the English system, if the velocity (expressed in feet per second) is divided by the frequency (expressed in cycles per second, or Hz), the wavelength is given in feet per cycle. If the metric system is used and the velocity (expressed in meters per second) is divided by the frequency (expressed in cycles per second), the wavelength is given in meters per cycle. Be sure to express both the wavelength and the frequency in the same units. (Feet per cycle and meters per cycle are normally abbreviated as feet or meters because one wavelength indicates one cycle.) Because this equation holds true for both transverse and

longitudinal waves, it is used in the study of both electromagnetic waves and sound waves.

1-30. Consider the following example:

Two cycles of a wave pass a fixed point every second, and the velocity of the wave train is 4 feet per second. What is the wavelength? The formula for determining wavelength is as follows:

$$\lambda = \frac{v}{f}$$

Where:

λ = wavelength in feet
v = velocity in feet per second
f = frequency in Hz

Given:

v = 4 feet per second
f = 2 Hz

Solution:

$$\lambda = \frac{v}{f}$$

$$\lambda = \frac{4 \text{ feet per second}}{2 \text{ Hz}}$$

$$\lambda = 2 \text{ feet}$$

1-31. In problems of this kind, be sure not to confuse wave velocity with frequency. Frequency is the number of cycles per unit of time (Hz). Wave velocity is the speed with which a wave train passes a fixed point.

1-32. Here is another problem:

If a wave has a velocity of 1,100 feet per second and a wavelength of 30 feet, what is the frequency of the wave?

By transposing the general equation:

$$f = \frac{v}{\lambda}$$

We have the equation:

$$\lambda = \frac{v}{f}$$

Given:

v = 1,100 feet per second
λ = 30 feet

Solution:

$$f = \frac{1{,}100 \text{ feet per second}}{30 \text{ feet}}$$

$$f = 36.67 \text{ Hz}$$

To find the velocity, rewrite the equation as follows:

$$v = \lambda f$$

1-33. Let us work one more problem, this time using the metric system.

Suppose the wavelength is 0.4 meters and the frequency is 12 kHz. What is the velocity? Use the following formula:

velocity = wavelength x frequency ($v = \lambda f$)

Given:

$\lambda =$ 0.4 meters

$f =$ 12 kHz

Solution:

$v = \lambda \times f$

$v =$ 0.4 meters x 12,000 Hz

$v =$ 4,800 meters per second

1-34. Other important characteristics of wave motion are reflection, refraction, diffraction, and the Doppler effect. Big words, but the concept of each is easy to see. For ease of understanding, we explain the first two characteristics using light waves, and the last two characteristics using sound waves. You should keep in mind that all waves react in a similar manner.

1-35. Within mediums, such as air, solids, or gases, a wave travels in a straight line. When the wave leaves the boundary of one medium and enters the boundary of a different medium, the wave changes direction. For our purposes, a boundary is an imaginary line that separates one medium from another.

1-36. When a wave passes through one medium and encounters a medium having different characteristics, three things can occur—

- Some of the energy can be reflected back into the initial medium.
- Some of the energy can be transmitted into the second medium where it may continue at a different velocity.
- Some of the energy can be absorbed by the medium. In some cases, all three processes (reflection, transmission, and absorption) may occur to some degree.

Reflection

1-37. Reflection waves are simply waves that are neither transmitted nor absorbed, but are reflected from the surface of the medium they encounter. If a wave is directed against a reflecting surface, such as a mirror, it will reflect or "bounce" from the mirror. Refer to figure 1-9. A wave directed toward the surface of the mirror is called the incident wave. When the wave bounces off of the mirror, it becomes known as the reflected wave. An imaginary line perpendicular to the mirror at the point at which the incident wave strikes the mirror's surface is called the normal, or perpendicular. The angle between the incident wave and the normal is called the angle of incidence. The angle between the reflected wave and the normal is called the angle of reflection. If the reflecting surface is smooth and polished, the angle between the incident ray and the normal will be the same as the angle between the reflected ray and the normal. This conforms to the law of reflection, which states: *The angle of incidence is equal to the angle of reflection*.

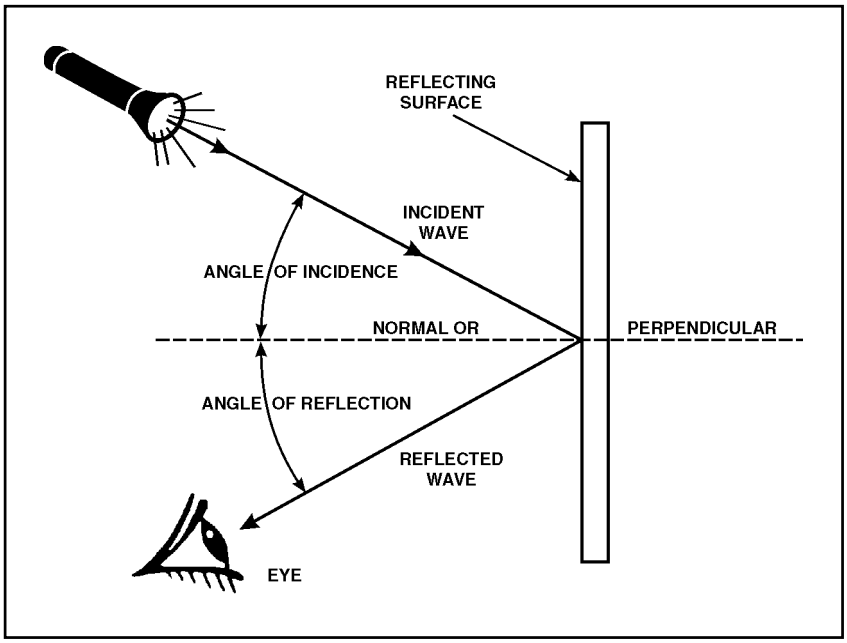

Figure 1-9. Reflection of a Wave

1-38. The amount of incident wave energy reflected from a given surface depends on the nature of the surface and the angle at which the wave strikes the surface. As the angle of incidence increases, the amount of wave energy reflected increases. The reflected energy is the greatest when the wave is nearly parallel to the reflecting surface. When the incident wave is perpendicular to the surface, more of the energy is transmitted into the substance and less is reflected. At any incident angle, a mirror reflects almost all of the wave energy, while a dull, black surface reflects very little.

Refraction

1-39. When a wave passes from one medium into another medium that has a different velocity of propagation, a change in the direction of the wave will occur. This changing of direction as the wave enters the second medium is called refraction. As in the discussion of reflection, the wave striking the boundary (surface) is called the incident wave, and the imaginary line perpendicular to the boundary is called the normal. The angle between the incident wave and the normal is called the angle of incidence. As the wave passes through the boundary, it is bent either toward or away from the normal. The angle between the normal and the path of the wave through the second medium is the angle of refraction.

1-40. A light wave passing through a block of glass is shown in figure 1-10. The wave moves from point A to B at a constant speed. This is the incident wave. As the wave penetrates the glass boundary at point B, the velocity of the wave is slowed down. This causes the wave to bend toward the normal. The wave then takes the path from point B to C through the glass and becomes both the refracted wave from the top surface and the incident wave to the lower surface. As the wave passes from the glass to the air (the second boundary), it is again refracted—this time away from the normal—and takes

the path from point C to D. As the wave passes through the last boundary, its velocity increases to the original velocity. As figure 1-10 shows, refracted waves can bend toward or away from the normal. This bending depends on the velocity of the wave through each medium. The broken line between points B and E is the path that the wave would travel if the two mediums (air and glass) had the same density.

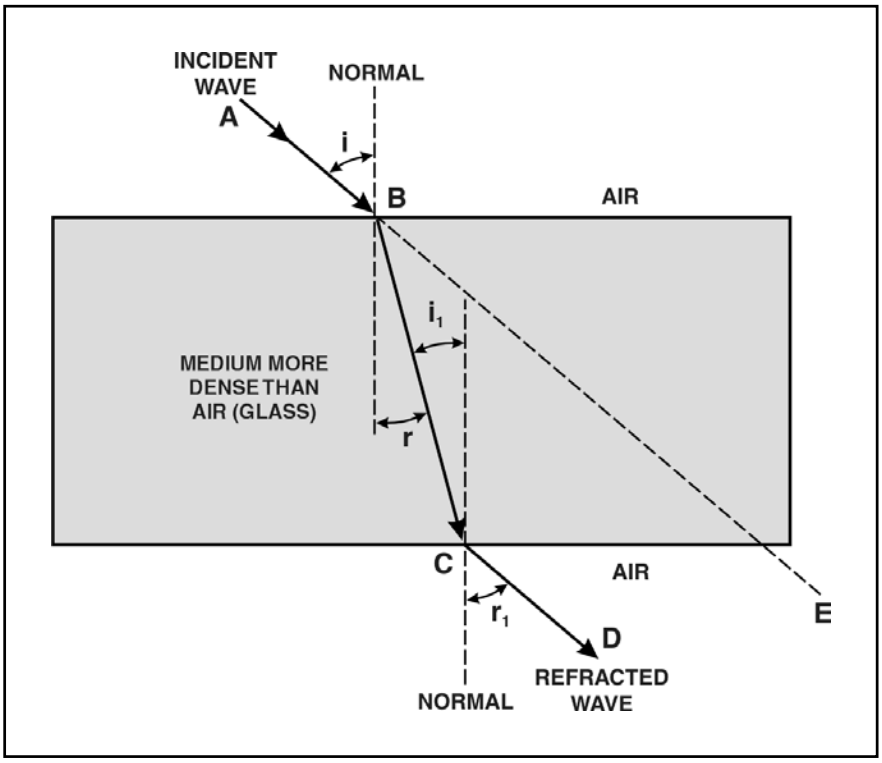

Figure 1-10. Refraction of a Wave

1-41. To summarize what figure 1-10 shows—

- If the wave passes from a less dense medium to a denser medium, it is bent toward the normal, and the angle of refraction (r) is less than the angle of incidence (i).
- If the wave passes from a denser to a less dense medium, it is bent away from the normal, and the angle of refraction (r_1) is greater than the angle of incidence (i_1).

1-42. You can more easily understand refraction by looking at figure 1-11. There is a plowed field in the middle of a parade ground. Think of the incident wave as a company of recruits marching four abreast at an angle across the parade ground to the plowed field, then crossing the plowed field and coming out on the other side onto the parade ground again. As the recruits march diagonally across the parade ground and begin to cross the boundary onto the plowed field, the front line is slowed down. Because the recruits arrive at the boundary at different times, they will begin to slow down at different times (number 1 slows down first and number 4 slows down last in each line). The net effect is a bending action. When the recruits leave the plowed field and reenter the parade ground, the reverse action takes place.

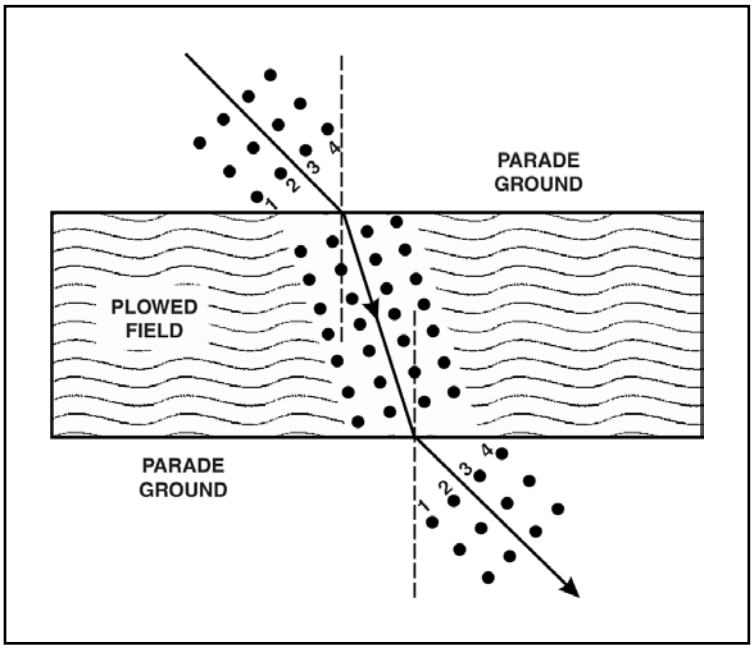

Figure 1-11. Analogy of Reflection

Diffraction

1-43. Diffraction is the bending of the wave path when the waves meet an obstruction. The amount of diffraction depends on the wavelength of the wave. Higher frequency waves are rarely diffracted in the normal world that surrounds us. Because light waves are high frequency waves, you will rarely see light diffracted. You can, however, observe diffraction in sound waves by listening to music. Suppose you are outdoors listening to a band. If you step behind a solid obstruction, such as a brick wall, you will hear mostly low notes. This is because the higher notes, having short wave lengths, undergo little or no diffraction and pass by or over the wall without wrapping around the wall and reaching your ears. The low notes, having longer wavelengths, wrap around the wall and reach your ears. This leads to the general statement that lower frequency waves tend to diffract more than higher frequency waves. Broadcast band (AM band) radio waves (lower frequency waves) often travel over a mountain to the opposite side from their source because of diffraction, while higher frequency TV and FM signals from the same source tend to be stopped by the mountain.

Doppler Effect

1-44. The last, but equally important, characteristic of a wave that we discuss is the Doppler effect. The Doppler effect is the apparent change in frequency or pitch when a sound source moves either toward or away from the listener, or when the listener moves either toward or away from the sound source. This principle, discovered by the Austrian physicist Christian Doppler, applies to all wave motion.

1-45. The apparent change in frequency between the source of a wave and the receiver of the wave is because of relative motion between the source and the receiver. To understand the Doppler effect, first assume that the

frequency of a sound from a source is held constant. The wavelength of the sound will also remain constant. If both the source and the receiver of the sound remain stationary, the receiver will hear the same frequency sound produced by the source. This is because the receiver is receiving the same number of waves per second that the source is producing. Now, if either the source or the receiver or both move toward the other, the receiver will perceive a higher frequency sound. This is because the receiver will receive a greater number of sound waves per second and interpret the greater number of waves as a higher frequency sound. Conversely, if the source and the receiver are moving apart, the receiver will receive a smaller number of sound waves per second and will perceive a lower frequency sound. In both cases, the frequency of the sound produced by the source will have remained constant.

1-46. For example, the frequency of the whistle on a fast-moving train sounds increasingly higher in pitch as the train is approaching than when the train is departing. Although the whistle is generating sound waves of a constant frequency, and though they travel through the air at the same velocity in all directions, the distance between the approaching train and the listener is decreasing. As a result, each wave has less distance to travel to reach the observer than the wave preceding it. Thus, the waves arrive with decreasing intervals of time between them.

1-47. These apparent changes in frequency, called the Doppler effect, affect the operation of equipment used to detect and measure wave energy. In dealing with electromagnetic wave propagation, the Doppler principle is used in equipment such as radar, target detection, weapons control, navigation, and sonar.

SOUND WAVES

1-48. As you know, sound travels through a medium by wave motion. Although sound waves and the electromagnetic waves used in the propagation of radio and radar differ, both types of waves have many of the same characteristics. Studying the principles of sound-wave motion will help you understand the actions of both sound waves and the more complex radio and radar electromagnetic waves. The major differences among sound waves, heat waves, and light waves are as follows:

- Their frequencies.
- Their types.
- The mediums through which they travel.
- The velocities at which they travel.

SOUND—WHAT IS IT?

1-49. The word sound is used in everyday speech to signify a variety of things. One definition of sound is the sensation of hearing. Another definition refers to a stimulus that is capable of producing the sensation of hearing. A third definition limits sound to what is actually heard by the human ear.

1-50. In the study of physics, sound is defined as a range of compression-wave frequencies to which the human ear is sensitive. For the purpose of this chapter, however, we need to broaden the definition of sound to include compression waves that are not always audible to the human ear. To distinguish frequencies in the audible range from those outside that range,

the words sonic, ultrasonic, and infrasonic are used. Sounds capable of being heard by the human ear are called sonics. The normal hearing range extends from about 20 to 20,000 hertz. In the Army to eliminate confusion when referring to different ranges of frequencies, an arbitrary dividing line has been established at 10,000 Hz. Even though the average person can hear sounds above 10,000 hertz, it is standard practice to refer to sounds above that frequency as ultrasonic. Sounds between 15 hertz and 10,000 hertz are called sonic. Sounds below 15 hertz are known as infrasonic (formerly referred to as subsonic) sounds.

REQUIREMENTS FOR SOUND

1-51. Recall that sound waves are compression waves. The existence of compression waves depends on the transfer of energy. To produce vibrations that become sounds, a mechanical device (the source) must first receive an input of energy. Next, the device must be in contact with a medium that will receive the sound energy and carry it to a receiver. If the device is not in contact with a medium, the energy will not be transferred to a receiver, and there will be no sound. Thus, three basic elements for transmission and reception of sound must be present before a sound can be produced. They are as follows:

- The source (or transmitter).
- A medium for carrying the sound (e.g., air, water, metal).
- The detector (or receiver).

1-52. A simple experiment provides convincing evidence that a medium must be present if sound is to be transferred. In figure 1-12, an electric bell is suspended by rubber bands in a bell jar from which the air can be removed. An external switch is connected from a battery to the bell so the bell may be rung intermittently. As the air is pumped out, the sound from the bell becomes weaker and weaker. If a perfect vacuum could be obtained, and if no sound were conducted out of the jar by the rubber bands, the sound from the bell would be completely inaudible. In other words, sound cannot be transmitted through a vacuum. When the air is admitted again, the sound is as loud as it was at the beginning. This experiment shows that when air is in contact with the vibrating bell, it carries energy to the walls of the jar, which in turn are set in vibration. Thus, the energy passes into the air outside of the jar and then on to the ear of the observer. This experiment illustrates that sound cannot exist in empty space (or a vacuum).

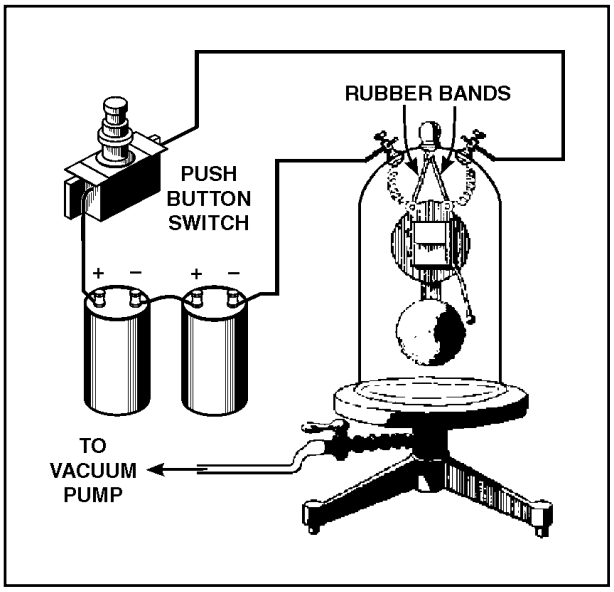

Figure 1-12. No Air, No Sound

1-53. Any object that moves rapidly back and forth, or vibrates, and thus disturbs the medium around it may be considered a source for sound. Bells, speakers, and stringed instruments are familiar sound sources.

1-54. The material through which sound waves travel is called the medium. The density of the medium determines the ease, distance, and speed of sound transmission. The higher the density of the medium, the slower sound travels through it.

1-55. The detector acts as the receiver of the sound wave. Because it does not surround the source of the sound wave, the detector absorbs only part of the energy from the wave and sometimes requires an amplifier to boost the weak signal.

1-56. As an illustration of what happens if one of these three elements is not present, let us refer to our experiment in which a bell was placed in a jar containing a vacuum. You could see the bell being struck, but you could hear no sound because there was no medium to transmit sound from the bell to you. Now let us look at another example in which the third element, the detector, is missing. You see a source (such as an explosion) apparently producing a sound, and you know the medium (air) is present, but you are too far away to hear the noise. Thus, as far as you are concerned, there is no detector and, therefore, no sound. We must assume, then, that sound can exist only when a source transmits sound through a medium, which passes it to a detector. Therefore, in the absence of any one of the basic elements (source, medium, and detector) there can be no sound.

TERMS USED IN SOUND WAVES

1-57. Sound waves vary in length according to their frequency. A sound having a long wavelength is heard at a low pitch (low frequency); one with a short wavelength is heard at a high pitch (high frequency). A complete wavelength is called a cycle. The distance from one point on a wave to the

corresponding point on the next wave is a wavelength. The number of cycles per second (hertz) is the frequency of the sound. The frequency of a sound wave is also the number of vibrations per second produced by the sound source.

CHARACTERISTICS OF SOUND

1-58. Sound waves travel at great distances in a very short time, but as the distance increases the waves tend to spread out. As the sound waves spread out, their energy simultaneously spreads through an increasingly larger area. Thus, the wave energy becomes weaker as the distance from the source is increased.

1-59. Sounds may be broadly classified into two general groups. One group is noise, which includes sounds such as the pounding of a hammer or the slamming of a door. The other group is musical sounds, or tones. The distinction between noise and tone is based on the regularity of the vibrations, the degree of damping, and the ability of the ear to recognize components having a musical sequence. You can best understand the physical difference between these kinds of sound by comparing the waveshape of a musical note, depicted in view A of figure 1-13, and the waveshape of noise, shown in view B. You can see by the comparison of the two waveshapes that noise makes a very irregular and haphazard curve and a musical note makes a uniform and regular curve.

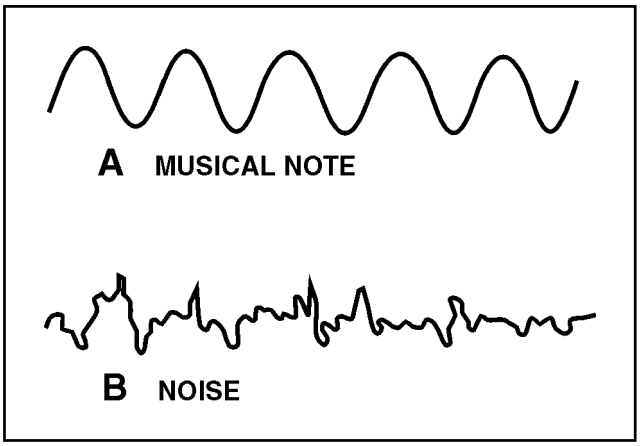

Figure 1-13. Musical Sound Versus Noise

1-60. Sound has three basic characteristics: pitch, intensity, and quality. Each of these three characteristics is associated with one of the properties of the source or the type of waves that it produces. The pitch depends upon the frequency of the waves, the intensity depends upon the amplitude of the waves, and the quality depends upon the form of the waves. With the proper combination of these characteristics, the tone is pleasant to the ear. With the wrong combination, the sound quality turns into noise.

Sound Pitch

1-61. The term pitch is used to describe the frequency of a sound. An object that vibrates many times per second produces a sound with a high pitch, as with a police whistle. The slow vibrations of the heavier strings of a violin

cause a low-pitched sound. Thus, the frequency of the wave determines pitch. When the frequency is low, sound waves are long; when it is high, the waves are short. A sound can be so high in frequency that the waves reaching the ear cannot be heard. Likewise, some frequencies are so low that the eardrums do not convert them into sound. The range of sound that the human ear can detect varies with each individual.

Sound Intensity

1-62. The intensity of sound, at a given distance, depends upon the amplitude of the waves. Thus, a tuning fork gives out more energy in the form of sound when struck hard than when struck gently. You should remember that when a tuning fork is struck, the sound is omnidirectional (heard in all directions), because the sound waves spread out in all directions, as shown in figure 1-14. You can see from the figure that as the distance between the waves and the sound source increases, the energy in each wave spreads over a greater area; hence, the intensity of the sound decreases. The speaking tubes sometimes used aboard a ship prevent the sound waves from spreading in all directions by concentrating them in one desired direction (unidirectional), producing greater intensity. Therefore, the sound is heard almost at its original intensity at the opposite end of the speaking tube. The unidirectional megaphone and the directional loudspeaker also prevent sound waves from spreading in all directions.

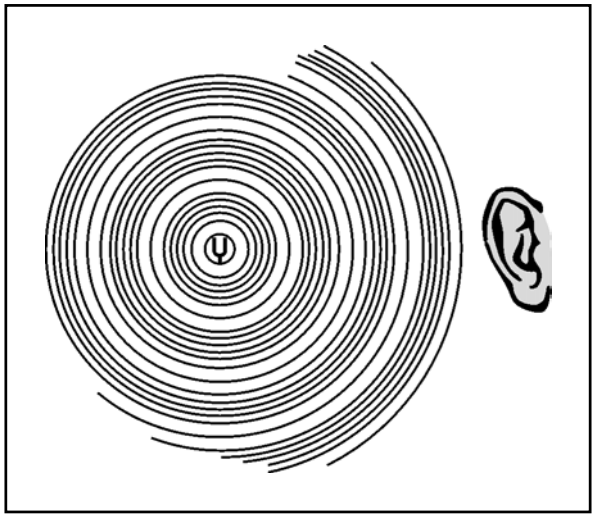

Figure 1-14. Sound Waves Spread in All Directions

1-63. Sound intensity and loudness are often mistakenly interpreted as having the same meaning. Although they are related, they are not the same. Sound intensity is a measure of the sound energy of a wave. Loudness, on the other hand, is the sensation the intensity (and sometimes frequency) the sound wave produces on the ear. Increasing the intensity causes an increase in loudness but not in a direct proportion. For instance, doubling the loudness of a sound requires about a tenfold increase in the intensity of the sound.

Sound Quality

1-64. Most sounds, including musical notes, are not pure tones. They are a mixture of different frequencies (tones). A tuning fork, when struck, produces a pure tone of a specific frequency. This pure tone is produced by regular vibrations of the source (tines of the tuning fork). On the other hand, scraping your fingernails across a blackboard creates only noise, because the vibrations are irregular. Each individual pipe of a pipe organ is similar to a tuning fork, and each pipe produces a tone of a specific frequency. But sounding two or more pipes at the same time produces a complex waveform. A tone that closely imitates any of the vowel sounds can be produced by selecting the proper pipes and sounding them at the same time. Figure 1-15 illustrates the combining of two pure tones to make a complex wave.

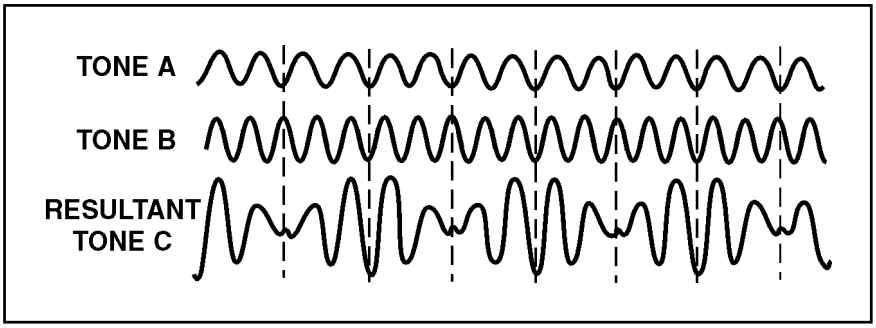

Figure 1-15. Combination of Tones

1-65. The quality of a sound depends on the complexity of its sound waves, such as the waves shown in tone C of figure 1-15. Almost all sounds (musical and vocal included) have complicated (complex) waveforms. Tone A is a simple wave of a specific frequency that can be produced by a tuning fork, piano, organ, or other musical instrument. Tone B is also a simple wave but at a different frequency. When the two tones are sounded together, the complex waveform in tone C is produced. Note that tone C has the same frequency as tone A with an increase in amplitude. The human ear could easily distinguish between tones A and tone C because of the quality. Therefore, we can say that quality distinguishes tones of like pitch and loudness when sounded on different types of musical instruments. It also distinguishes the voices of different persons.

VELOCITY OF TRANSMISSION

1-66. Sound waves travel through any medium to a velocity that is controlled by the medium. Varying the frequency and intensity of the sound waves will not affect the speed of propagation. The elasticity and density of a medium are the two basic physical properties that govern the velocity of sound through the medium.

1-67. Elasticity is the ability of a strained body to recover its shape after deformation, as from a vibration or compression. The measure of elasticity of a body is the force it exerts to return to its original shape.

1-68. The density of a medium or substance is the mass per unit volume of the medium or substance. Raising the temperature of the medium (which

decreases its density) has the effect of increasing the velocity of sound through the medium.

1-69. The velocity of sound in an elastic medium is expressed by the formula:

$$V = \sqrt{\frac{E}{d}}$$

1-70. Even though solids such as steel and glass are far denser than air, their elasticities are so much greater that the velocities of sound in them are 15 times greater than the velocity of sound in air. Using elasticity as a rough indication of the speed of sound in a given medium, we can state as a general rule that sound travels faster in harder materials (such as steel), slower in liquids, and slowest in gases. Density has the opposite effect on the velocity of sound, that is, with other factors constant, a denser material (such as lead) passes sound more slowly.

1-71. At a given temperature and atmospheric pressure, all sound waves travel in air at the same speed. Thus the velocity that sound will travel through air at 32°F (0°C) is 1,087 feet per second. But for practical purposes, the speed of sound in air may be considered as 1,100 feet per second. Table 1-1 gives a comparison of the velocity of sound in various mediums.

Table 1-1. Comparison of Velocity of Sound in Various Mediums

MEDIUM	*TEMPERATURE*		*VELOCITY (Ft/Sec)*
	ºF	*ºC*	
Air	32	0	1,087
Air	68	20	1,127
Aluminum	68	20	16,700
Carbon Dioxide	32	0	856
Fresh Water	32	0	4,629
Fresh Water	68	20	4,805
Hydrogen	32	0	4,219
Lead	32	20	4,030
Salt Water	32	0	4,800
Salt Water	68	20	4,953
Steel	32	0	16,410
Steel	68	20	16,850

ACOUSTICS

1-72. The science of sound is called acoustics. This subject could fill volumes of technical books, but we scratch only the surface in this chapter. We present the important points that you need for a better understanding of sound waves. Acoustics, like sound, relates to the sense of hearing. It also deals with the production, control, transmission, reception, and effects of sound. For the present, we are concerned only with the last relationship—the effects of sound. These same effects will be used throughout your study of wave propagation.

Echo

1-73. An echo is the reflection of the original sound wave as it bounces off a distant surface. Just as a rubber ball bounces back when it is thrown against a hard surface, sound waves also bounce off most surfaces. As you have learned from the study of the law of conservation of energy, a rubber ball never bounces back with as much energy as the initial bounce. Similarly, a reflected sound wave is not as loud as the original sound wave. In both cases, some of the energy is absorbed by the reflecting surface. Only a portion of the original sound is reflected, and only a portion of the reflected sound returns to the listener. For this reason, an echo is never as loud as the original sound. Sound reflections (echoes) have many applications. The most important of these applications can be found in the use of depth-finding equipment (the fathometer) and sonar. The fathometer sends sound-wave pulses from the bottom of a ship and receives echoes from the ocean floor to indicate the depth of the ocean beneath the ship. The sonar transmits a pulse of sound energy and receives the echo to indicate range and bearing of objects or targets in the ocean depths.

Refraction

1-74. When sound waves traveling at different velocities pass obliquely (at an angle) from one medium into another, the waves are refracted; that is, their line of travel is bent. Refraction occurs gradually when one part of a sound wave is traveling faster than the other parts. For example, the wind a few feet above the surface of the earth has a greater velocity than that near the surface because friction retards the lower layers (see figure 1-16). The velocity of the wind is added to the velocity of the sound through the air. The result is that the upper portion of the sound wave moves faster than the lower portion and causes a gradual change in the direction of travel of the wave. Refraction causes sound to travel farther with the wind than against it.

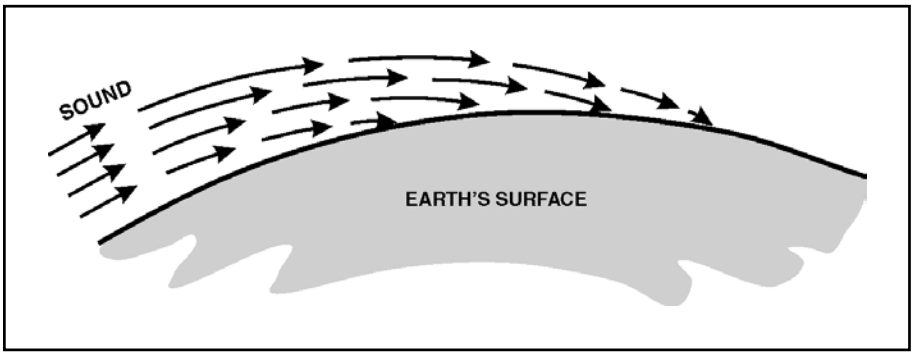

Figure 1-16. Refraction of Sound

Reverberation

1-75. In empty rooms or other confined spaces, sound may be reflected several times to cause what is known as reverberation. Reverberation is the multiple reflections of sound waves. Reverberations seem to prolong the time during which a sound is heard. Examples of this effect often occur in nature. For instance, the discharge of lightning causes a sharp, quick sound. By the time this sound has reached the ears of a distant observer, it is usually drawn out into a prolonged roar by reverberations that we call thunder. A similar case often arises with underwater sound equipment. Reverberations

from nearby points may continue for such a long time that they interfere with the returning echoes from targets.

Interference

1-76. Any disturbance, man-made or natural, that causes an undesirable response or the degradation of a wave is referred to as interference. Two sound waves moving simultaneously through the same medium will advance independently, each producing a disturbance as if the other were not present. If the two waves have the same frequency—are in phase with each other and are moving in the same direction—they are additive and are said to interfere constructively. If the two waves have the same frequency and are moving in the same direction, but out of phase with each other, they are subtractive and are said to interfere destructively. If these two subtractive waves have equal amplitudes, the waves cancel each other. This addition or subtraction of waves is often called interference.

Resonance

1-77. At some time during your life you probably observed someone putting his or her head into an empty barrel or other cavity and making noises varying in pitch. When that person's voice reached a certain pitch, the tone produced seemed much louder than the others. The reason for this phenomenon is that at that a certain pitch the frequency of vibrations of the voice matched the resonant (or natural) frequency of the cavity. The resonant frequency of a cavity is the frequency at which the cavity body will begin to vibrate and create sound waves. When the resonant frequency of the cavity was reached, the sound of the voice was reinforced by the sound waves created by the cavity, resulting in a louder tone. This phenomenon occurs whenever the frequency of vibrations is the same as the natural frequency of a cavity, and is called resonance.

Noise

1-78. The most complex sound wave that can be produced is noise. Noise has no tonal quality. It distracts and distorts the sound quality that was intended to be heard. Noise is generally an unwanted disturbance caused by spurious waves originating from man-made or natural sources, such as a jet breaking the sound barrier, or thunder.

LIGHT WAVES

1-79. The concepts used to describe the behavior of waves—including reflection, refraction, and diffraction—can help you understand the behavior of light and light waves described below. The relationship between light and light waves (rays) is the same as for sound and sound waves.

1-80. Light is a form of electromagnetic energy. It can be produced by various means (e.g., mechanical, electrical, and chemical). We can see objects because the light waves (rays) they give off or reflect reach our eyes.

PROPAGATION OF LIGHT

1-81. The exact nature of light is not fully understood, although scientists have been studying the subject for many centuries. Some experiments seem to show that light is composed of tiny particles, and some suggest that it is made up of waves.

1-82. One theory after another attracted the approval and acceptance of physicists. Today, some scientific phenomena can be explained only by the wave theory and others only by the particle theory. Physicists, constantly searching for some new discovery that would bring these two theories into agreement, gradually have come to accept a theory that combines the principles of the two theories.

1-83. According to the view now generally accepted, light is a form of electromagnetic radiation; that is, light and similar forms of radiation are made up of moving electric and magnetic fields. These two fields are explained thoroughly later in this chapter.

ELECTROMAGNETIC THEORY OF LIGHT

1-84. James Clark Maxwell, a brilliant Scottish scientist of the mid-nineteenth century, constructed an oscillating electrical circuit, which he used to show that electromagnetic waves could move through empty space. Light eventually was proved to be electromagnetic.

1-85. Current light theory says that light is made up of very small packets of electromagnetic energy called photons (the smallest unit of radiant energy). These photons move at a constant speed in the medium through which they travel. Photons move at a faster speed through a vacuum than they do in the atmosphere, and at a slower speed through water than air.

1-86. The electromagnetic energy of light is a form of electromagnetic radiation. Light and similar forms of radiation are made up of moving electric and magnetic forces and move as waves. Electromagnetic waves move in a manner similar to the waves produced by the pebble dropped in the pool of water discussed earlier in this chapter. The transverse waves of light from a light source spread out in expanding circles much like the waves in the pool. However, the waves in the pool are very slow and clumsy in comparison with light, which travels approximately 186,000 miles per second.

1-87. Light radiates from its source in all directions until absorbed or diverted by some substance (figure 1-17). The lines drawn from the light source (a light bulb in the example in figure 1-17) to any point on one of these waves indicate the direction in which the waves are moving. These lines, called radii of the spheres, are formed by the waves and are called light rays. Although single rays of light do not exist, light “rays” are used in illustrations as a convenient method to show the direction in which light is traveling at any point.

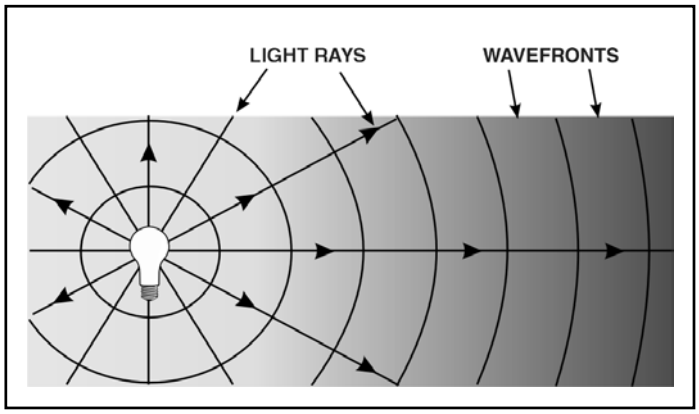

Figure 1-17. Waves and Radii from a Nearby Light Source

1-88. A large volume of light is called a beam; a narrow beam is called a pencil; and the smallest portion of a pencil is called a light ray. A ray of light can be illustrated as a straight line. This straight line drawn from a light source represents an infinite number of rays radiating in all directions from the source.

FREQUENCIES AND WAVELENGTHS

1-89. Compared to sound waves, the frequency of light waves is very high and the wavelength is very short. To measure these wavelengths conveniently, a special unit of measure called an angstrom unit, or more usually, an angstrom (Å), was devised. Another common unit used to measure these waves is the millimicron (mm), which is one millionth of a millimeter. One mF equals ten angstroms. One angstrom equals 10^{-10} meters.

FREQUENCIES AND COLOR

1-90. For our discussion of light wave waves, we use the millimicron measurement. The wavelength of a light determines the color of the light. Figure 1-18 indicates that light with a wavelength of 700 millimicrons is red, and that light with a wavelength of 500 millimicrons is blue-green. This illustration shows approximate wavelengths of the different colors in the visible spectrum. In fact, the color of light depends on its frequency, not its wavelength. However, light is measured in wavelengths. When the wavelength of 700 millimicrons is measured in a medium such as air, it produces the color red, but the same wave measured in a different medium will have a different wavelength. When red light that has been traveling in air enters glass, it loses speed. Its wavelength becomes shorter or compressed, but it continues to be red. This phenomenon indicates that the color of light depends on frequency and not on wavelength. The color scale in figure 1-18 is based on the wavelengths in air.

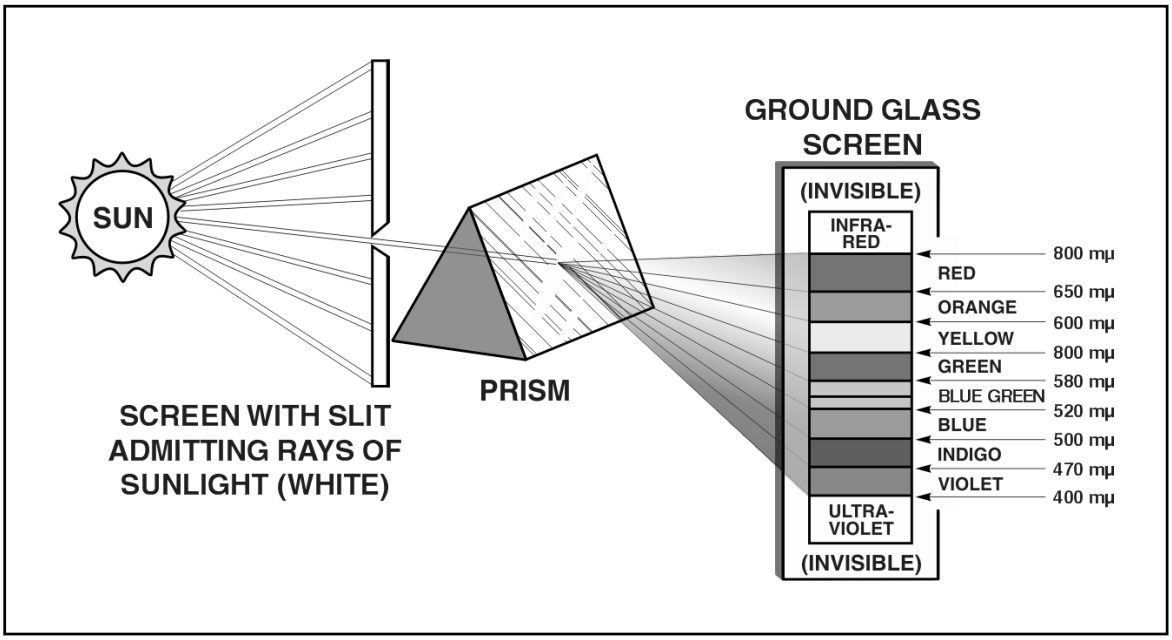

Figure 1-18. Use of a Prism to Split White Light into Different Colors

1-91. When a beam of white light (sunlight) is passed through a prism, as shown in figure 1-18, it is refracted and broken down into its component wavelengths. (This phenomenon of breaking light down into its component wavelengths is known as dispersion.) Each of these wavelengths causes a different reaction of the eye, which sees the various colors that compose the visible spectrum. The visible spectrum is recorded as a mixture of red, orange, yellow, green, blue, indigo, and violet. White light results when the primaries (red, green, and blue) are mixed together in overlapping beams of light. (These are not the primary colors used in mixing pigments, such as in paint.) Furthermore, the complementary or secondary colors (magenta, yellow, and cyan) may be shown with equal ease by mixing any two of the primary colors in overlapping beams of light. Thus, red and green light mixed in equal intensities make yellow light; green and blue produce cyan (blue-green light); and blue and red correctly mixed produce magenta (a purplish red light).

LIGHT AND COLOR

1-92. All objects absorb some of the light that falls on them. An object appears to be a certain color because it absorbs all of the light waves except those whose frequency corresponds to that particular color. Those waves are reflected from the surface, strike your eye, and cause you to see the particular color. The color of an object therefore depends on the frequency of the electromagnetic wave reflected.

LUMINOUS BODIES

1-93. If an object is the source of light energy, it is called luminous. If the object is not the source of light but reflects light, it is called an illuminated body.

1-94. Certain bodies, such as the sun, a gas flame, and an electric light filament are visible because they are light sources. They are called self-luminous bodies. Objects other than self-luminous bodies become visible only when they are in the presence of light from luminous bodies.

1-95. Most nonluminous bodies are visible because they diffuse or reflect the light that falls on them. A good example of a nonluminous diffusing body is the moon, which shines only because the sunlight falling onto its surface is diffused.

1-96. Black objects do not diffuse or reflect light. They are visible only when outlined against a background of light from a luminous or diffusing body.

PROPERTIES OF LIGHT

1-97. When light waves, which travel in straight lines, encounter any substance, they are transmitted, reflected, or absorbed. These effects are illustrated in figure 1-19. When light strikes a substance, some absorption and some reflection always take place. No substance completely transmits, reflects, or absorbs all of the light rays that reach its surface. Substances that transmit almost all the light waves that fall upon them are said to be transparent. A transparent substance is one through which you can see clearly. Clear glass is transparent because it transmits light rays without diffusing them (figure 1-20, view A). There is no known perfectly transparent substance, but many substances are nearly so. Substances through which some light rays can pass but through which objects cannot be seen clearly because the rays are diffused are called translucent (figure 1-20, view B). The frosted glass of a light bulb and a piece of oiled paper are examples of translucent materials. Substances that do not transmit any light rays are called opaque (figure 1-20, view C). Opaque substances can either reflect or absorb virtually all of the light rays that fall upon them.

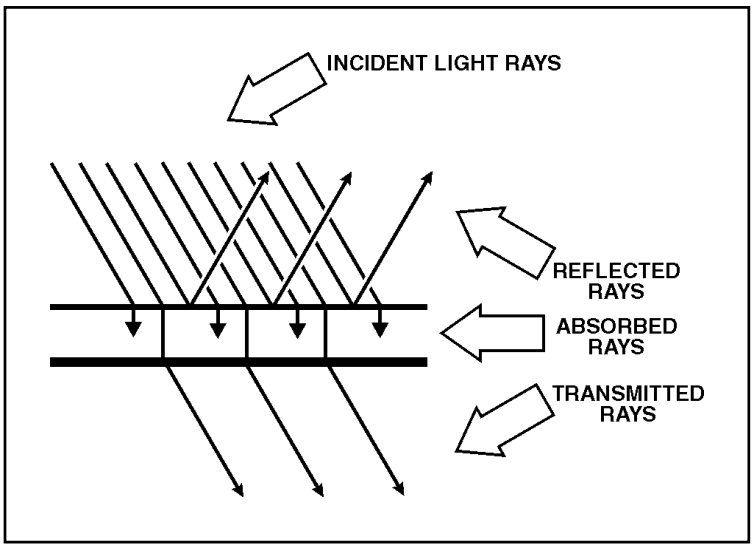

Figure 1-19. Light Waves Reflected, Absorbed, and Transmitted

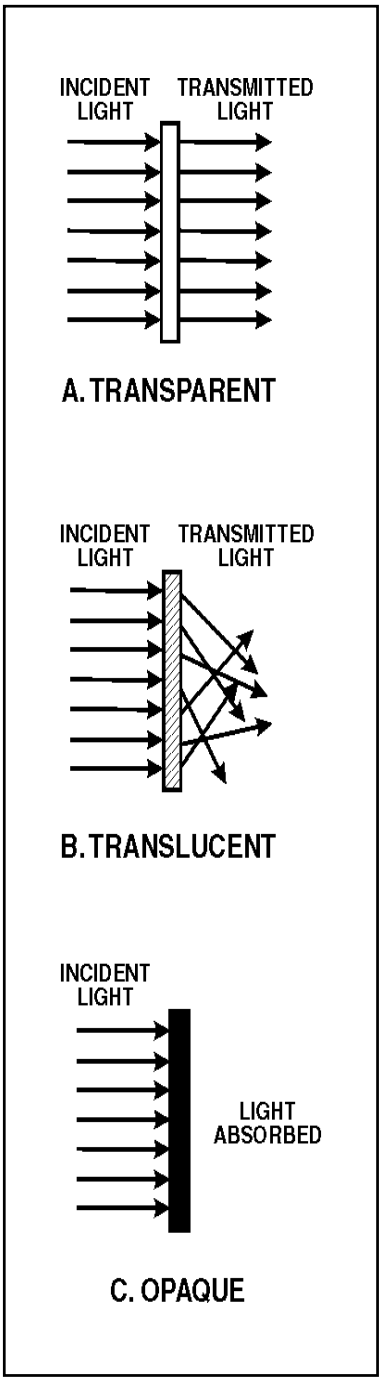

Figure 1-20. Transparent, Translucent, and Opaque Substances

Speed of Light

1-98. You probably have heard people say, "quick as lightning" or "fast as light" to describe rapid motion; nevertheless, it is difficult to realize how fast light actually travels. Not until recent years have scientists been able to measure accurately the speed of light.

1-99. Prior to the mid-seventeenth century, scientists thought that light required no time at all to pass from the source to the observer. Then, in 1675, Ole Roemer, a Danish astronomer, discovered that light travels approximately 186,000 miles per second in space. At this velocity, a light beam can circle the earth 7 1/2 times in one second.

1-100. The speed of light depends on the medium through which the light travels. In empty space, the speed is 186,000 (1.86×10^5) miles per second. It is almost the same in air. In water, it slows down to approximately 140,000 (1.4×10^5) miles per second. In glass, the speed of light is 124,000 (1.24×10^5) miles per second. In other words, the speed of light decreases as the density of the substance through which the light passes increases.

1-101. The velocity of light, which is the same as the velocity of other electromagnetic waves, is considered to be constant, at 186,000 miles per second. If expressed in meters, the velocity of light is 300,000,000 meters per second.

Reflection of Light

1-102. Light waves obey the law of reflection in the same manner as other types of waves. Consider the straight path of a light ray admitted through a narrow slit into a darkened room. The straight path of the beam is made visible by illuminated dust particles suspended in the air. If the light beam is made to fall onto the surface of a mirror or other reflecting surface, however, the direction of the beam changes sharply. The light can be reflected in almost any direction, depending on the angle at which the mirror is held.

1-103. As shown earlier in figure 1-9, if a light beam strikes a mirror, the angle at which the beam is reflected depends on the angle at which it strikes the mirror. The beam approaching the mirror is the incident or striking beam, and the beam leaving the mirror is the reflected beam.

1-104. The term "reflected light" simply refers to light waves that are neither transmitted nor absorbed, but are thrown back from the surface of the medium they encounter. This phenomenon is described more fully in the discussions of radio waves (chapter 2) and antennas (chapter 4).

Refraction of Light

1-105. The change of direction that occurs when a ray of light passes from one transparent substance into another of different density is called refraction. Refraction is due to the fact that light travels at various speeds in different transparent substances. For example, water never appears as deep as it really is, and objects under water appear to be closer to the surface than they really are. A bending of the light rays causes these impressions.

1-106. Another example of refraction is the apparent bending of a spoon when it is immersed in a cup of water. The bending seems to take place at the surface of the water, or exactly at the point where there is a change of density. Obviously, the spoon does not bend from the pressure of the water. The light forming the image of the spoon is bent as it passes from the water (a medium of high density) to the air (a medium of comparatively low density).

1-107. Without refraction, light waves would pass in straight lines through transparent substances without any change of direction. Refer back to figure 1-10, which shows refraction of a wave. As you can see, all rays striking the glass at any angle other than perpendicular are refracted. However, the perpendicular ray, which enters the glass normal to the surface, continues through the glass and into the air in a straight line—no refraction takes place.

Diffusion of Light

1-108. When light is reflected from a mirror, the angle of reflection of each ray equals the angle of incidence. When light is reflected from a piece of plain white paper, however, the reflected beam is scattered, or diffused, as shown in figure 1-21. Because the surface of the paper is not smooth, the reflected light is broken up into many light beams that are reflected in all directions.

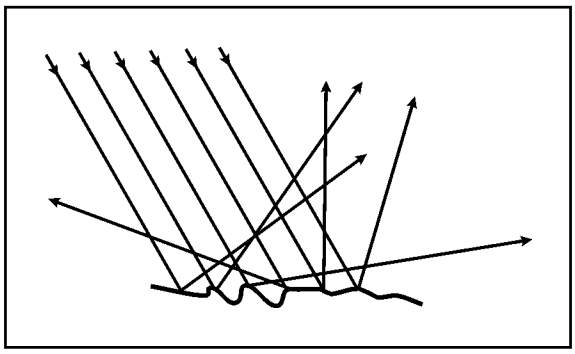

Figure 1-21. Diffusion of Light

Absorption of Light

1-109. As illustrated in figure 1-21, a light beam is reflected and diffused when it falls onto a piece of white paper. If a light beam falls onto a piece of black paper, the black paper absorbs most of the light rays and very little light is reflected from the paper. If the surface on which the light beam falls is perfectly black, there is no reflection; that is, the light is totally absorbed. No matter what kind of surface light falls on, however, some of the light is absorbed.

COMPARISON OF LIGHT WAVES WITH SOUND WAVES

1-110. There are two main differences between sound waves and light waves. The first difference is in velocity. Sound waves travel through air at the speed of approximately 1,100 feet per second; light waves travel through air and empty space at a speed of approximately 186,000 miles per second (300,000,000 meters per second). The second difference is that sound is composed of longitudinal waves (alternate compressions and expansions of matter) and light is composed of transverse waves in an electromagnetic field.

1-111. Although both are forms of wave motion, sound requires a solid, liquid, or gaseous medium, whereas light can travel through empty space. The denser the medium, the greater the speed of sound. The opposite is true of light. Light travels approximately one-third slower in water than in air. Sound travels through all substances, but light cannot pass through opaque materials.

1-112. Frequency affects both sound and light. A certain range of sound frequencies produces sensations that you can hear. A slow vibration (low frequency) in sound gives the sensation of a low note. A more rapid sound vibration (higher frequency) produces a higher note. Likewise, a certain range of light frequencies produces sensations that you can see. Violet light is produced at the high-frequency end of the light spectrum, while red light is produced at the low-frequency end of the light spectrum. A change in frequency of sound waves causes an audible sensation—a difference in pitch. A change in the frequency of a light wave causes a visual sensation—a difference in color. For a comparison of light waves with sound waves, see Table 1-2.

Table 1-2. Comparison of Light Waves and Sound Waves

	SOUND WAVES	***LIGHT WAVES***
Velocity in air	Approximately 1,100 feet per second.	Approximately 186,000 miles per second (300,000,000 meters per second).
Form	A form of wave motion.	A form of wave motion.
Wave composition	Longitudinal.	Transverse.
Transmitting medium	All substances.	Empty space and all substances except opaque materials.
Relation of transmitting medium velocity to velocity	The denser the medium, the greater the speed.	The denser the medium, the slower the speed.
Sensations produced	Hearing.	Seeing.
Variations in sensations produced	A low frequency causes a low note; a high frequency causes a high note.	A low frequency causes red light; a high frequency causes violet light.

ELECTROMAGNETIC SPECTRUM

1-113. Light is one kind of electromagnetic energy. There are many other types of electromagnetic energy, including heat energy and radio energy. The only difference between the various types of electromagnetic energy is the frequency of their waves (rate of vibration). The term spectrum is used to designate the entire range of electromagnetic waves arranged in order of their frequencies. The visible spectrum contains only those waves that stimulate the sense of sight. As a technician, you might be expected to maintain equipment that uses electromagnetic waves within, above, and below the visible spectrum.

1-114. There are neither sharp dividing lines nor gaps in the electromagnetic spectrum. Figure 1-22 illustrates how portions of the electromagnetic spectrum overlap. Notice that only a small portion of the electromagnetic spectrum contains visible waves, or light, that can be seen by the human eye.

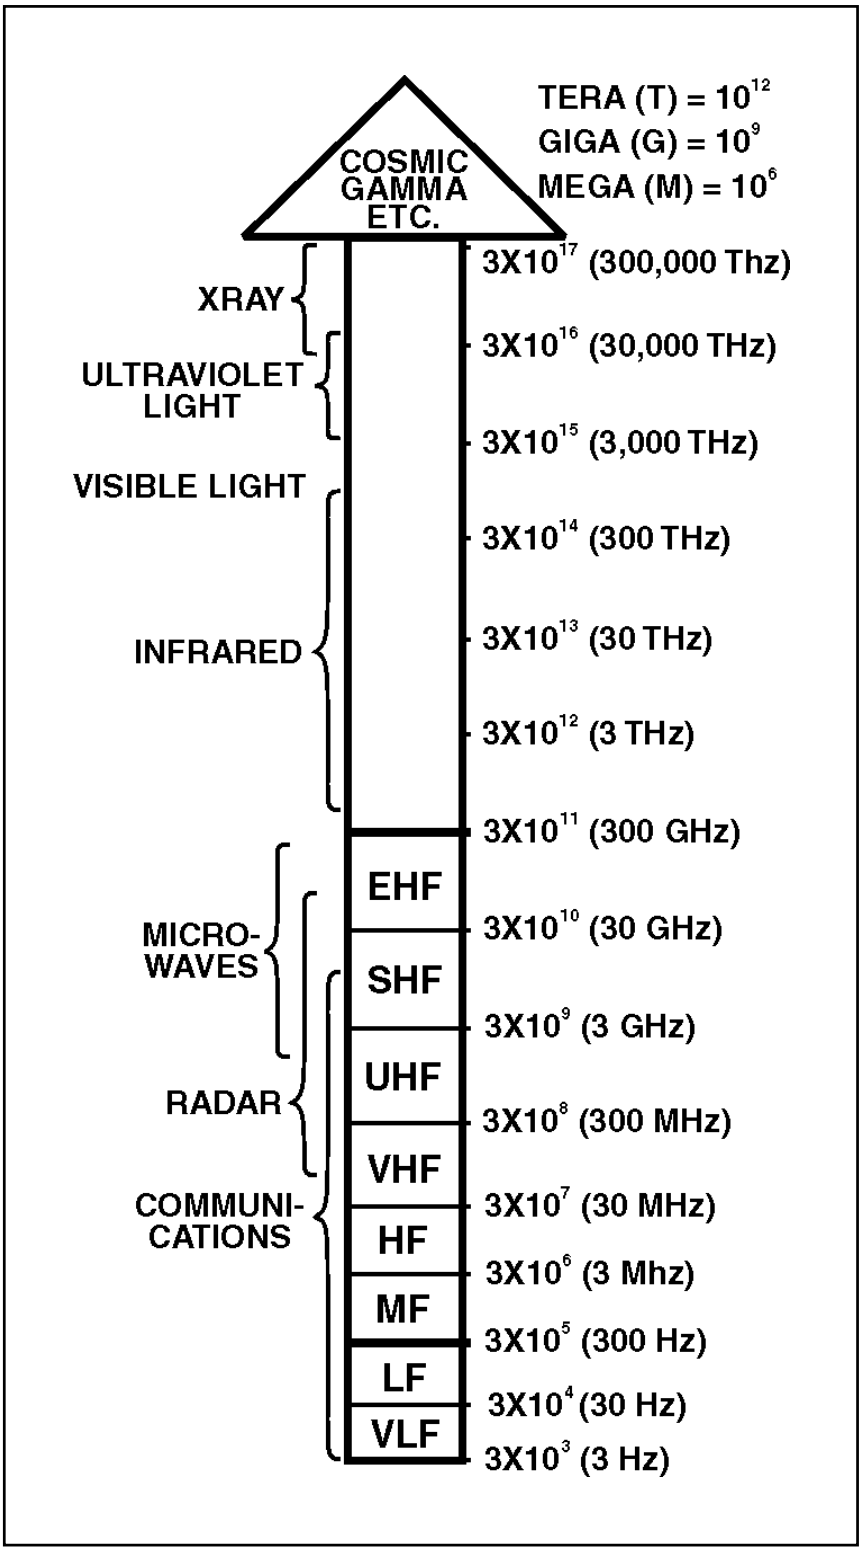

Figure 1-22. Electromagnetic Spectrum

ELECTROMAGNETIC WAVES

1-115. In general, the same principles and properties of light waves apply to the communications electromagnetic waves you are about to study. The electromagnetic field is used to transfer energy (as communications) from point to point. The basic antenna is a propagation source of these electromagnetic waves.

THE BASIC ANTENNA

1-116. The study of antennas and electromagnetic wave propagation is essential to a complete understanding of radio communication, radar, loran, and other electronic systems. Figure 1-23 shows a simple radio communication system. In the illustration, the transmitter is an electronic device that generates radio-frequency energy. The energy travels through a transmission line (discussed in chapter 3) to an antenna. The antenna converts the energy into radio waves that radiate into space from the antenna at the speed of light. The radio waves travel through the atmosphere or space until they are either reflected by an object or absorbed. If another antenna is placed in the path of the radio waves, it absorbs part of the waves and converts them to energy. This energy travels through another transmission line and is fed to a receiver. From this example, you can see that the requirements for a simple communications system are as follows:

- Transmitting equipment.
- Transmission line.
- Transmitting antenna.
- Medium.
- Receiving antenna.
- Receiving equipment.

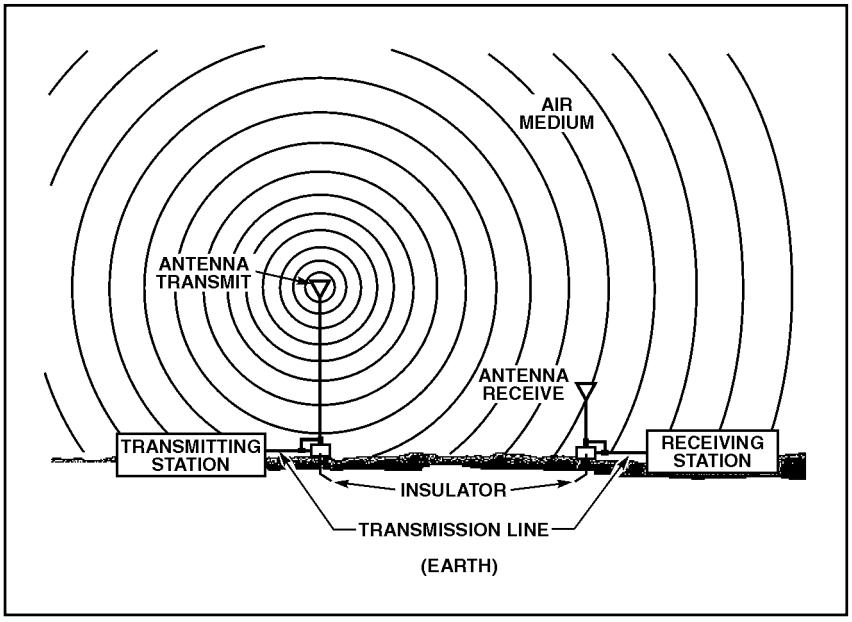

Figure 1-23. Simple Radio Communication System

1-117. An antenna is a conductor or a set of conductors used either to radiate electromagnetic energy into space or to collect this energy from space. Figure 1-24 shows an antenna. View A is a drawing of an actual antenna; view B is a cut-away view of the antenna; and view C is a simplified diagram of the antenna.

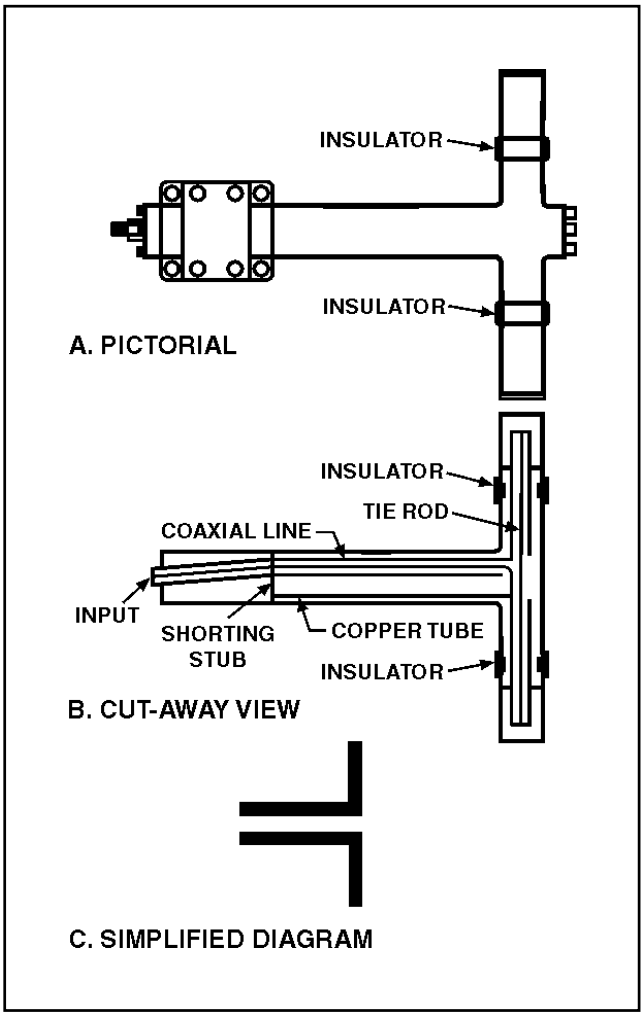

Figure 1-24. Antenna

COMPONENTS OF THE ELECTROMAGNETIC WAVE

1-118. An electromagnetic wave consists of two primary components—an electric field and a magnetic field. The electric field results from the force of voltage, and the magnetic field results from the flow of current.

1-119. Although electromagnetic fields that are radiated are commonly considered to be waves, under certain circumstances their behavior makes them appear to have some of the properties of particles. In general, however, it is easier to picture electromagnetic radiation in space as horizontal and vertical lines of force oriented at right angles to each other. These lines of force are made up of an electric field (E) and a magnetic field (H), which together make up the electromagnetic field in space.

1-120. The electric and magnetic fields radiated from an antenna form the electromagnetic field. This field is responsible for the transmission and reception of electromagnetic energy through free space. An antenna, however, is also part of the electrical circuit of a transmitter or a receiver and is equivalent to a circuit containing inductance, capacitance, and resistance. Therefore, the antenna can be expected to display definite voltage and current relationships with respect to a given input. A current through the antenna produces a magnetic field, and a charge on the antenna produces an electric field. These two fields combine to form the induction field. To help you gain a better understanding of antenna theory, the following subsections review some basic electrical concepts, including voltage and its electric field, current and its magnetic field, and their relationship to the propagation of electrical energy.

Electric Field

1-121. Around every electrically charged object is a force field that can be detected and measured. This force field can cause electric charges to move in the field. When an object is charged electrically, there is either a greater or a smaller concentration of electrons than normal. Thus, a difference of potential exists between a charged object and an uncharged object. An electric field is, therefore, associated with a difference of potential, or a voltage.

1-122. Lines that are drawn to show the paths along which the force acts commonly represent this invisible field of force. The lines representing the electric field are drawn in the direction that a single positive charge would normally move under the influence of that field. A large electric force is shown by a large concentration of lines; a few lines indicate a weak force.

1-123. When a capacitor is connected across a source of voltage, such as a battery, it is charged by a particular amount, depending on the voltage and the value of capacitance (see figure 1-25). Because of the EMF (electromotive force) of the battery, negative charges flow to the lower plate, leaving the upper plate positively charged. Along with the growth of charge, the electric field is also building up. The flux lines are directed from the positive to the negative charges and at right angles to the plates. When the capacitor is fully charged, the voltage of the capacitor is equal to the voltage of the source and opposite in polarity. The charged capacitor stores the energy in the form of an electric field. It can be said, therefore, that an electric field indicates voltage.

1-124. If the two plates of the capacitor are spread farther apart, the electric field must curve to meet the plates at right angles (figure 1-26). The straight lines in view A of figure 1-26 become arcs in view B, and approximately semicircles in view C, where the plates are in a straight line. Instead of flat metal plates, as in the capacitor, the two elements can take the form of metal rods or wires and form the basic antenna.

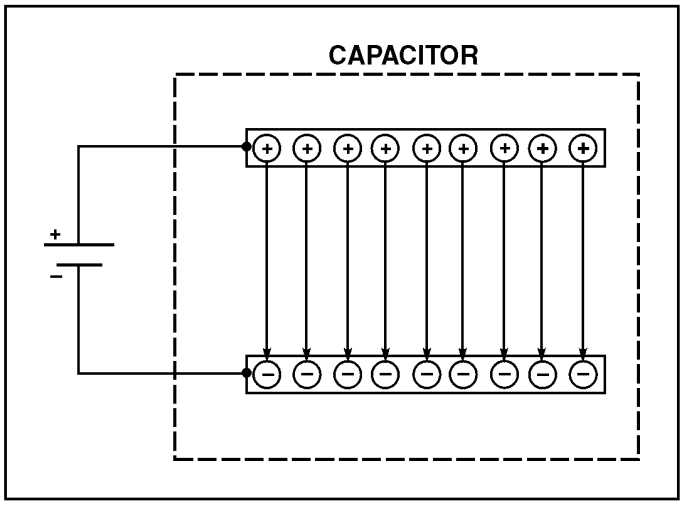

Figure 1-25. Electric Fields between Plates

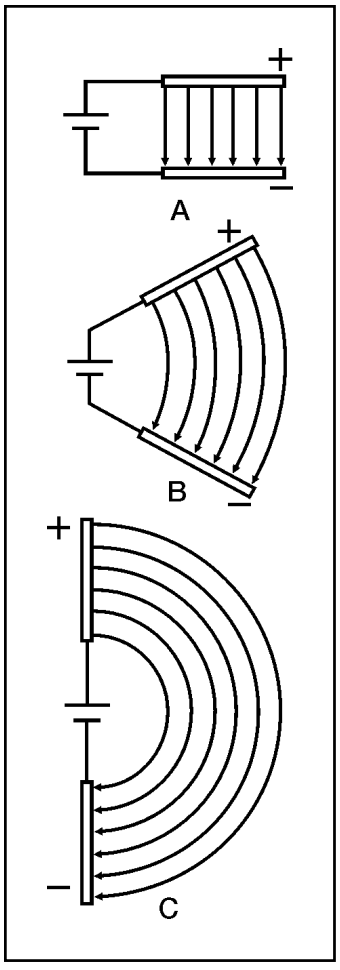

Figure 1-26. Electric Fields between Plates at Different Angles

1-125. In figure 1-27, two rods replace the plates of the capacitor, and the battery is replaced by an AC source generating a 60-hertz signal. On the positive alternation of the 60-hertz generator, the electric field extends from the positively charged rod to the negatively charged rod, as shown. On the negative alternation, the charge is reversed. The previous explanation of electrons moving from one plate to the other of the capacitor in figure 1-25 can also be applied to the rods in figure 1-27.

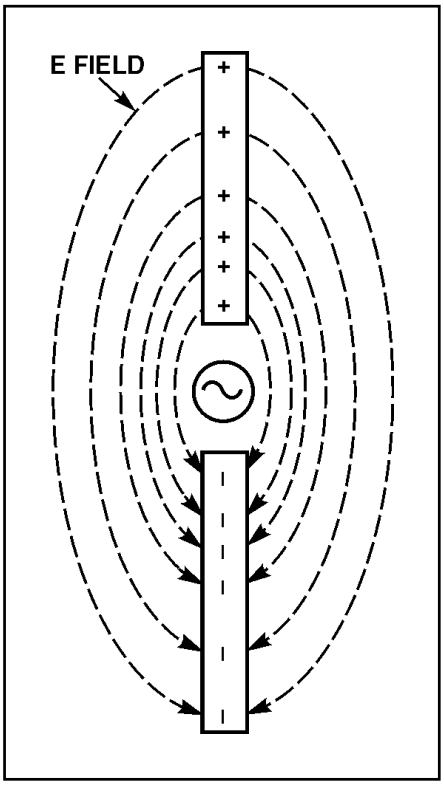

Figure 1-27. Electric Fields between Elements

1-126. The polarity of charges and the direction of the electric fields will reverse polarity and direction periodically at the frequency of the voltage source. The electric field will build up from zero to maximum in one direction and then collapse back to zero. Next, the field will build up to maximum in the opposite direction and then collapse back to zero. This complete reversal occurs during a single cycle of the source voltage. The half-wave dipole antenna (two separate rods in line as illustrated in figure 1-27) is the fundamental element normally used as a starting point of reference in any discussion concerning the radiation of electromagnetic energy into space. If RF energy from the AC generator (or transmitter) is supplied to the element of an antenna, the voltage across the antenna lags the current by 90 degrees. The antenna acts as if it were a capacitor.

Magnetic Field

1-127. When current flows through a conductor, a magnetic field is set up in the area surrounding the conductor. In fact, any moving electrical charge will create a magnetic field. The magnetic field is a region in space where a

magnetic force can be detected and measured. There are two other fields involved—an induction field, which exists close to the conductor carrying the current, and the radiation field, which becomes detached from the current-carrying rod and travels through space.

1-128. To represent the magnetic field, lines of force are again used to illustrate the energy. Magnetic lines are not drawn between the rods, nor between high- and low-potential points, as the E lines that were discussed earlier. The flow of current rather than the force of voltage creates magnetic lines. The magnetic lines of force, therefore, are drawn at right angles to the direction of current flow.

1-129. The magnetic fields that are set up around two parallel rods, as shown in figure 1-28 view A, are in maximum opposition. Rod 1 contains a current flowing from the generator, while rod 2 contains a current flowing toward the generator. As a result, the direction of the magnetic field surrounding rod 1 is opposite the direction of the magnetic field surrounding rod 2. This will cause cancellation of part or all of both magnetic fields with a resultant decrease in radiation of the electromagnetic energy. View B illustrates that if the far ends of rods 1 and 2 are separated from each other while the rods are still connected to the generator at the near ends, more space—and consequently less opposition—will occur between the magnetic fields of the two rods. View C illustrates that placing the rods in line makes the currents through both rods flow in the same direction. Therefore, the two magnetic fields are in the same direction; thus, maximum electromagnetic radiation into space can be obtained.

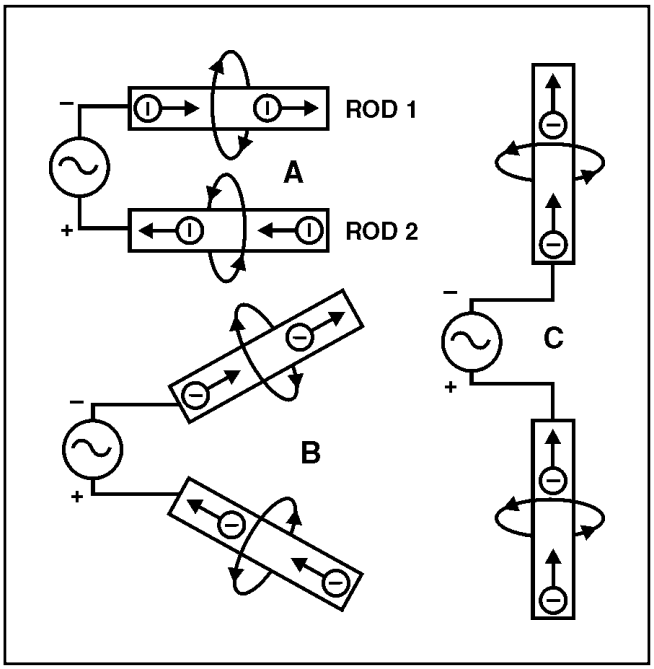

Figure 1-28. Magnetic Fields around Elements

1-130. Magnetic lines of force are indicated by the letter H and are called H lines. The direction of the magnetic lines may be determined by use of the left-hand rule for a conductor: If you grasp the conductor in your left hand

with the thumb extended in the direction of the current flow, your fingers will point in the direction of the magnetic lines of force. In view C of figure 1-28, the direction of current flow is upward along both halves of the elements (conductors). The lines of magnetic force (flux) form concentric loops that are perpendicular to the direction of current flow. The arrowheads on the loops indicate the direction of the field. The left-hand rule, illustrated in figure 1-29, is used to determine the direction of the magnetic field. The direction of the magnetic lines may be determined as follows: If you grasp the conductor in your left hand with the thumb extended in the direction of the current flow, then the rough circles formed by the fingers indicate the direction of the magnetic field.

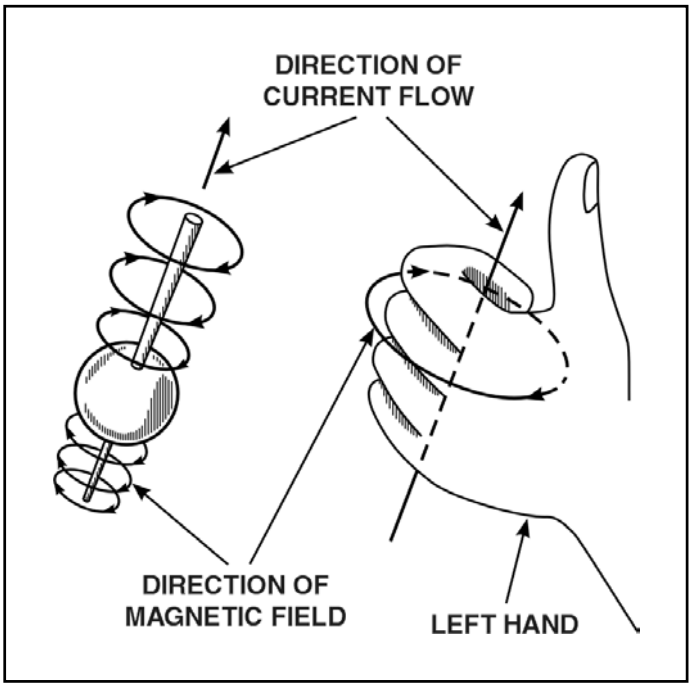

Figure 1-29. Left-Hand Rule for Conducting Elements

Combined Electric and Magnetic Fields

1-131. The generator, shown in figure 1-30, provides the voltage, which creates an electric field, and current, which creates a magnetic field. This source voltage and current build up to maximum values in one direction during one half-cycle, and then build up to maximum values in the other direction during the next half-cycle. Both the electric and magnetic fields alternate from minimum through maximum values in synchronization with the changing voltage and current. The electric and magnetic fields reach their maximum intensity one quarter-cycle apart. These fields form the induction field. Because the current and voltage that produce these E and H fields are 90 degrees out of phase, the fields will also be 90 degrees out of phase.

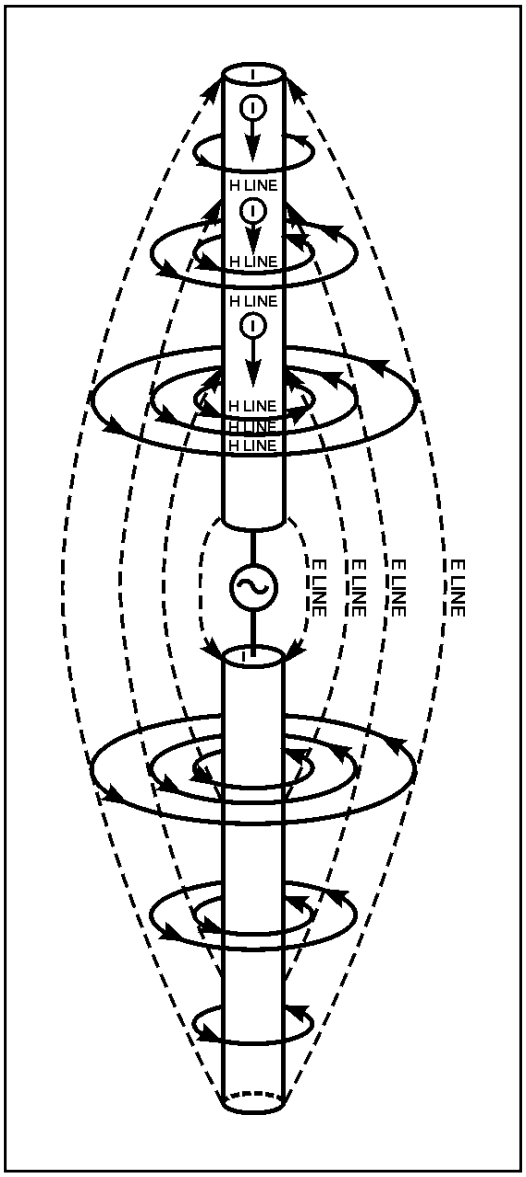

Figure 1-30. Relationship of E-Lines and Current Flow

SUMMARY

Now that you have completed this chapter, let us review some of the new terms, concepts, and ideas you have learned. You should have a thorough understanding of these principles before moving on to chapter 2.

Wave propagation is an invisible force that enables man to communicate over long distances. Wave transmission can take many forms, such as light, sound, and radio.

Light is a form of wave motion that can be seen. Heat cannot normally be seen, but can be felt. Radio waves cannot be seen or felt.

Wave motion can be seen in action by throwing a pebble into a pool of still water. The ripples that move toward the edge of the pool demonstrate the propagation theory.

Figure 1-Sum 1. Formation of Waves in Water

The transverse wave is a type of wave motion. Radio, light, and heat waves are examples of transverse waves.

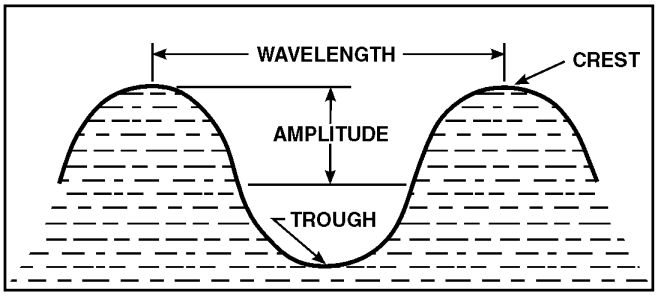

Figure 1-Sum 2. Elements of a Wave

The longitudinal wave is another type of wave motion. The sound wave is the only example of a longitudinal wave given in this text.

Source, medium, and detector (receiver) are the three requirements for all wave motion.

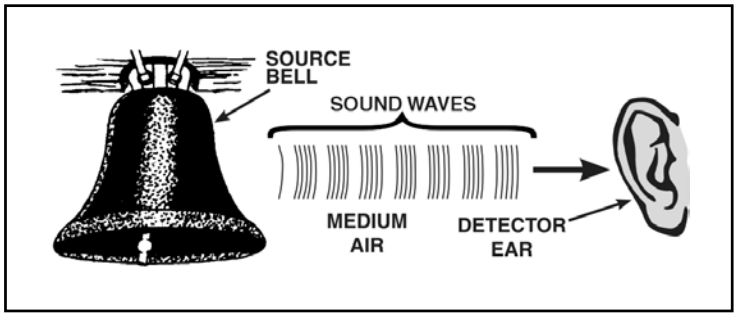

Figure 1-Sum 3. The Three Elements of Sound

A source can be anything that emits or expends energy (waves).

The medium is the vehicle for carrying waves from one point to another. Water, air, metal, and empty space are examples of mediums. Empty space can serve as a medium for electromagnetic waves but not for sound waves.

The sound detector absorbs the waves emitted by the source. The human ear is an example of a detector.

Hertz, which is abbreviated Hz, is used in lieu of "cycle per second" when referring to radio frequencies.

Velocity of propagation is the speed (or rate) at which the crest of a wave moves through a medium. Velocity can be calculated by using the formula:

$$v = \lambda f$$

Where v is velocity of propagation and is expressed in feet (meters) per second, λ is the wavelength in feet (meters), and f is the frequency in hertz.

Reflection occurs when a wave strikes an object and bounces back (toward the source). The wave that moves from the source to the object is called the incident wave, and the wave that moves away from the object is called the reflected wave.

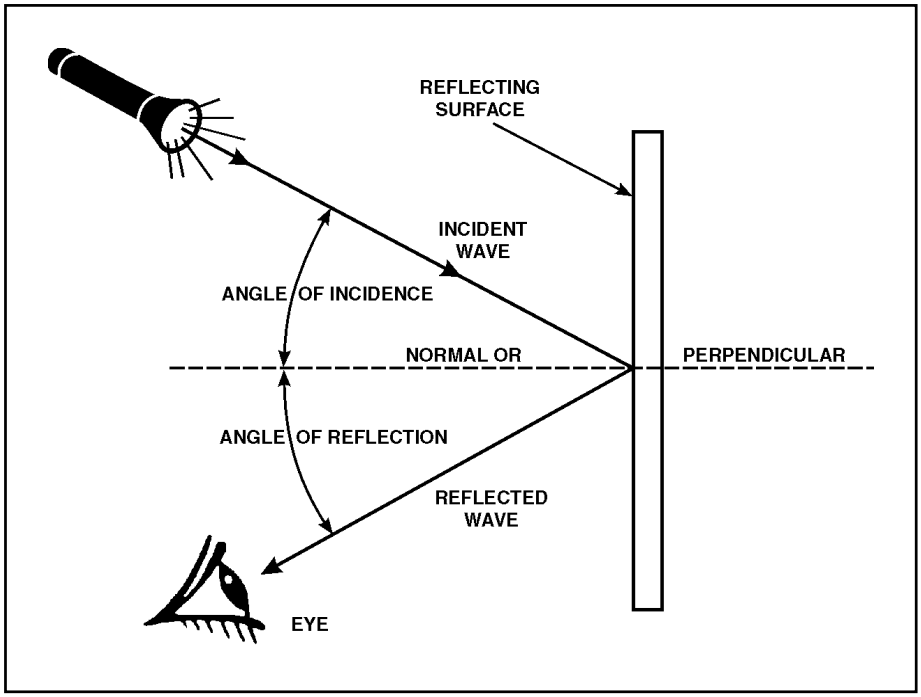

Figure 1-Sum 4. Reflection of a Wave

The law of reflection states that *the angle of incidence is equal to the angle of reflection*.

Refraction occurs when a wave traveling through two different mediums passes through the boundary of the mediums and bends toward or away from the normal.

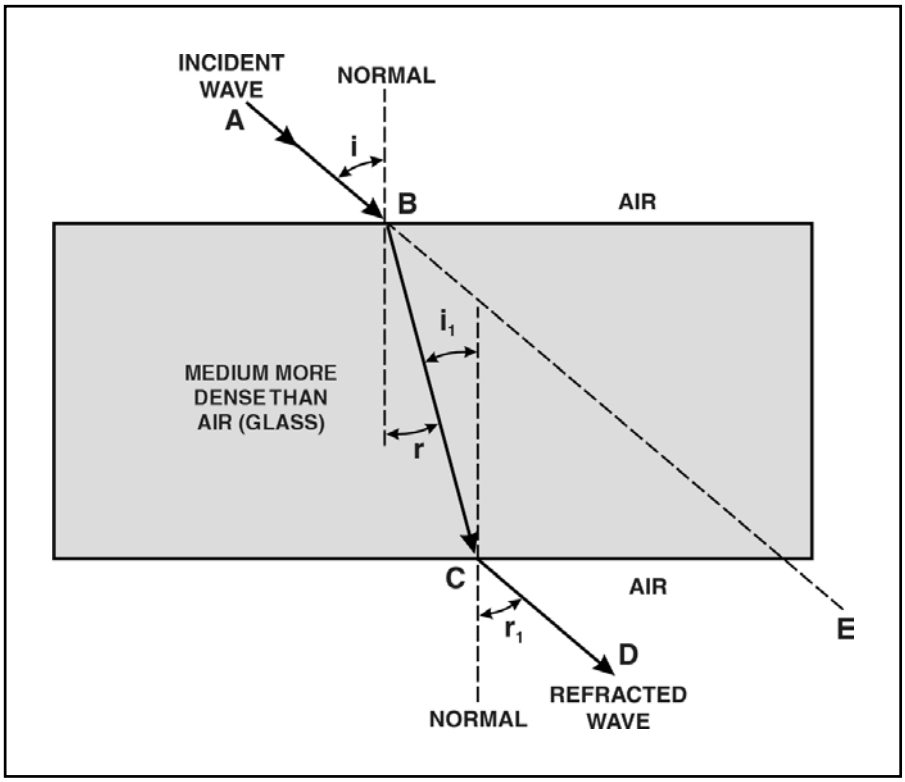

Figure 1-Sum 5. Refraction of a Wave

Diffraction can account for the ability of the AM radio waves (due to their low frequency) to travel over a mountain, while FM and TV signals (due to their higher frequencies) are blocked.

The Doppler effect is the apparent change in frequency of a source as it moves toward or away from a detector. It can affect the operation of equipment used to detect and measure wave energy.

Characteristics of sound can be audible to the human ear or it can be outside the hearing range.

Noise and tones are the two general groups that broadly classify all sounds.

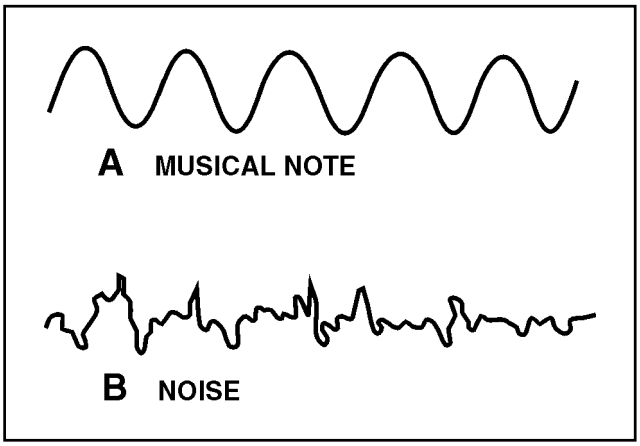

Figure 1-Sum 6. Musical Sound Versus Noise

Pitch, intensity, and quality are the three basic characteristics of sound. Pitch describes the frequency of sound. Intensity describes how much energy is transmitted. Quality enables us to distinguish one sound from another.

The density of a medium, temperature, and atmospheric pressure affect the velocity of sound. If temperature, density, or pressure increases, the velocity of sound increases and vice versa.

Acoustics is the science of sound and relates to the sense of hearing.

Echo is an example of reflection. Sound echoes are used in sonar and depth finders to determine or measure the range of an object or the depth of the ocean bottom.

Reverberation is the multiple reflections of sound waves. The prolonged roar of thunder is caused by reverberations. With underwater sound equipment, reverberations of nearby objects may interfere with returning echoes from actual targets.

Interference occurs when two waves move simultaneously through a medium. They can interfere constructively, destructively, or produce a resultant of zero.

Resonance occurs when an objects vibrates (or resonates) at its natural frequency. When different frequencies are produced inside a cavity, the sound from the cavity sounds louder at its resonant frequency than at all other frequencies.

Noise is any disturbance that distracts from or distorts the quality of sound.

A photon is the smallest unit of radiant energy that makes up light waves and radio waves.

Angstrom (Å) units are used for measuring the wavelength of light. One angstrom = 10^{-10} meters .

The visible spectrum contains all the colors between infrared and ultraviolet. Infrared and ultraviolet are invisible to the human eye.

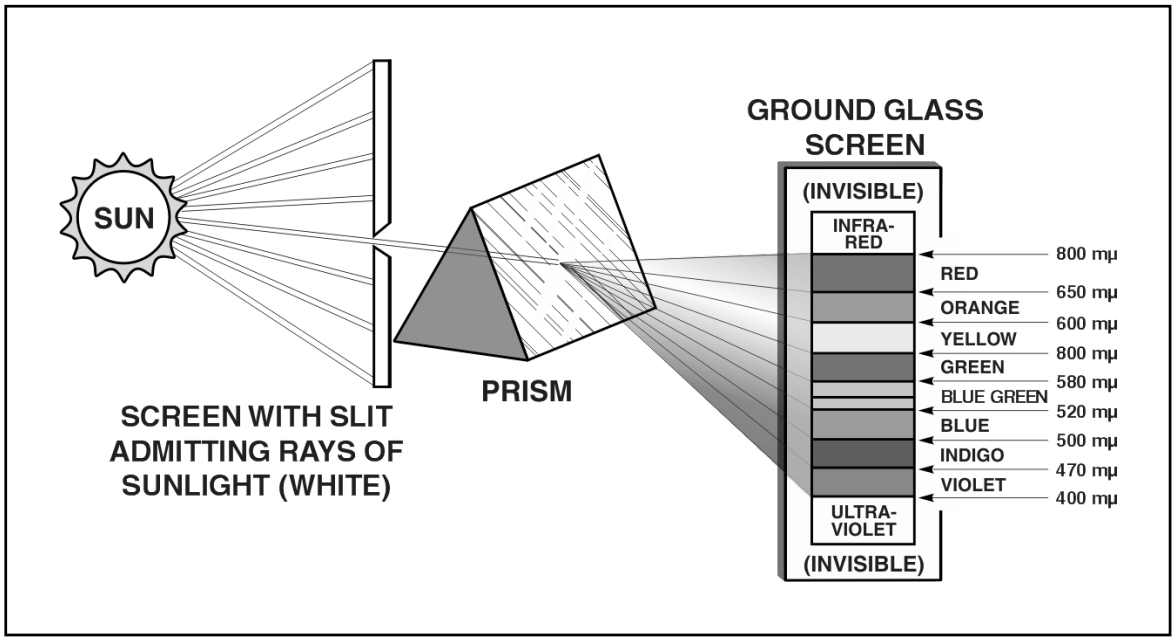

Figure 1-Sum 7. Use of a Prism to Split White Light into Different Colors

The primary colors of light are red, green, and blue. These primaries can be mixed to make any color between red and violet. If the three colors are mixed equally, they produce white light.

The complementary colors of light are magenta, yellow, and cyan. Mixing any two of the primary colors together in overlapping beams produces them.

The speed of light in empty space is considered to be 186,000 miles per second (or 300,000,000 meters per second). This speed varies in different mediums, but the constant of 186,000 miles per second is always used as the speed of light.

The electromagnetic spectrum is the complete range of electromagnetic frequencies from 3 kHz to beyond 300,000 THz. Audio frequencies (15 Hz to 20 kHz) are not electromagnetic energy and are not included in the electromagnetic spectrum. The electromagnetic field consists of an electric field and a magnetic field. These fields are responsible for the transmission and reception of electromagnetic energy through free space.

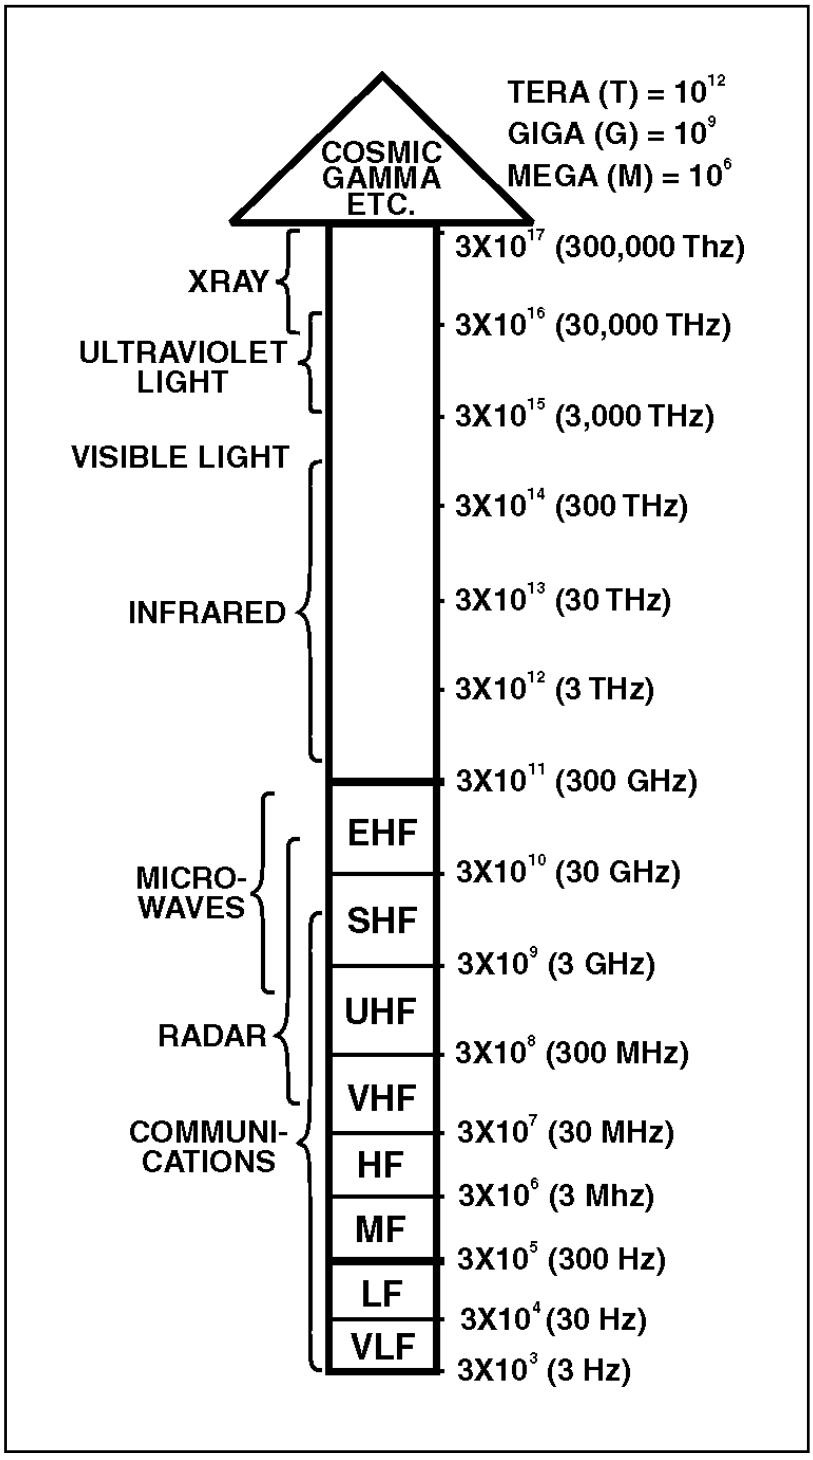

Figure 1-Sum 8. Electromagnetic Spectrum

Check-on-Learning Questions

Wave Propagation

When you are satisfied that you have answered every question to the best of your ability, check your answers using appendix A. If you missed eight or more questions, you should review the chapter, paying particular attention to the areas in which your answers were incorrect.

1. What is propagation?
2. How is a wave defined as it applies to wave propagation?
3. What is wave motion?
4. What are some examples of wave motion?
5. What type of wave motion is represented by the motion of water?
6. What are some examples of transverse waves?
7. What example of a longitudinal wave was given in the text?
8. What are the three requirements for a wave to be propagated?
9. What is a cycle?
10. What is wavelength (λ)?
11. What is the law of reflection?
12. When a wave is reflected from a surface, energy is transferred. When is the transfer of energy greatest?
13. When is the transfer of energy minimum?
14. A refracted wave occurs when a wave passes from one medium into another medium. What determines the angle of refraction?
15. The apparent change in frequency or pitch because of motion is explained by what effect?
16. What term describes sounds capable of being heard by the human ear?
17. Are all sounds audible to the human ear? Why?
18. Sound waves transmitted from a source are sometimes weak when they reach the detector. What instrument is needed to boost the weak signal?
19. What are the three basic requirements for sound?
20. What are the two general groups of sound?
21. What are the three basic characteristics of sound?
22. What is the normal audible range of the human ear?
23. What is intensity as it pertains to sound?
24. What characteristic of sound enables a person to distinguish one musical instrument from another, if they are all playing the same note?
25. How do density and temperature affect the velocity of sound?
26. What term is used to mean the science of sound?

27. A sound wave that is reflected back toward the source is known as what type of sound?
28. What is the term for multiple reflections of sound waves?
29. A cavity that vibrates at its natural frequency produces a louder sound than at other frequencies. What term is used to describe this phenomenon?
30. What do we call a disturbance that distracts or distorts the quality of sound?
31. What are three means of producing light?
32. What is the smallest unit of radiant energy?
33. What unit is used to measure the different wavelengths of light?
34. What are the three primary colors of light?
35. What are the three secondary colors of light?
36. White light falls upon a dull, rough, dark-brown object. Will the light primarily be reflected, diffused, or absorbed by the object?
37. What color will be emitted by a dull, rough, black object when white light falls upon it?
38. A substance that transmits light but through which an object cannot be seen clearly is known as what kind of substance?
39. At what speed does light travel?
40. A light wave enters a sheet of glass at a perfect right angle to the surface. Is the majority of the wave reflected, refracted, transmitted, or absorbed?
41. When light strikes a piece of white paper, the light is reflected in all directions. What do we call this scattering of light?
42. What three examples of electromagnetic energy are mentioned in the text?
43. What is the main difference between the bulk of the electromagnetic spectrum and the visible spectrum?
44. What are the two components (fields) that make up the electromagnetic wave?
45. What do we call a conductor (or set of conductors) that radiates electromagnetic energy into space?
46. What do we call the field that is created between two rods when a voltage is applied to them?
47. When current flows through a conductor, a field is created around the conductor. What do we call this field?
48. An induction field is created around a conductor when current flows through it. What do we call the field that detaches itself from the conductor and travels through space?

Chapter 2

Radio Wave Propagation

LEARNING OBJECTIVES

2-1. Upon completing this chapter, you should be able to do the following:

- State what the electromagnetic field is and what components make up the electromagnetic field.
- State the difference between the induction field and the radiation field.
- State what radio waves are.
- List the components of a radio wave and define the terms cycle, frequency, harmonics, period, wavelength, and velocity as applied to radio wave propagation.
- Compute the wavelength of radio waves.
- State how radio waves are polarized, vertically and horizontally.
- State what reflection, refraction, and diffraction are as applied to radio waves.
- State what influence the earth's atmosphere has on radio waves and list the different layers of the earth's atmosphere.
- Identify a ground wave and a sky wave, and describe the effects of the ionosphere on the sky wave.
- Identify the structure of the ionosphere.
- Define density of layer, frequency, angle of incidence, skip distance, and skip zone.
- Describe propagation paths.
- Describe fading, multipath fading, and selective fading. Describe propagation paths.
- State how transmission losses affect radio wave propagation.
- State how electromagnetic interference, man-made/natural interference, and ionospheric disturbances affect radio wave propagation. State how transmission losses affect radio wave propagation.
- Identify variations in the ionosphere.
- Identify the maximum, optimum, and lowest usable frequencies of radio waves.
- State what temperature inversion is, how frequency predictions are made, and how weather affects frequency.
- State what tropospheric scatter is and how it affects radio wave propagation.

ELECTROMAGNETIC FIELDS

2-2. The way energy is propagated into free space is a source of great dispute among people concerned with it. Although many theories have been proposed, the following theory adequately explains the phenomena and has been widely accepted. There are two basic fields associated with every antenna; an induction field and a radiation field. The field associated with the energy stored in the antenna is the induction field. This field is said to provide no part in the transmission of electromagnetic energy through free space. However, without the presence of the induction field, there would be no energy radiated.

INDUCTION FIELD

2-3. Figure 2-1, which illustrates a low-frequency generator connected to an antenna, will help you understand how the induction field is produced. Let us follow the generator through one cycle of operation.

2-4. Initially, you can consider that the generator output is zero and that no fields exist about the antenna, as shown in figure 2-1, view A. Now assume that the generator produces a slight potential and has the instantaneous polarity shown in view B. Because of this slight potential, the antenna capacitance acts as a short, allowing a large flow of current (I) through the antenna in the direction shown. This current flow, in turn, produces a large magnetic field about the antenna. Because the flow of current at each end of the antenna is minimum, the corresponding magnetic fields at each end of the antenna are also minimum. As time passes, charges—which oppose antenna current and produce an electrostatic field (E field)—collect at each end of the antenna. Eventually, the antenna capacitance becomes fully charged and stops current flow through the antenna. Under this condition, the electrostatic field is maximum, and the magnetic field (H field) is fully collapsed, as shown in view C.

2-5. As the generator potential decreases back to zero, the potential of the antenna begins to discharge. During the discharging process, the electrostatic field collapses and the direction of current flow reverses, as shown in figure 2-1, view D. When the current again begins to flow, an associated magnetic field is generated. Eventually, the electrostatic field completely collapses, the generator potential reverses, and current is maximum, as shown in view E. As charges collect at each end of the antenna, an electrostatic field is produced and current flow decreases. This causes the magnetic field to begin collapsing. The collapsing magnetic field produces more current flow, a greater accumulation of charge, and a greater electrostatic field. The antenna gradually reaches the condition shown in view F, where current is zero and the collected charges are maximum.

2-6. As the generator potential again decreases toward zero, the antenna begins to discharge and the electrostatic field begins to collapse. When the generator potential reaches zero, discharge current is maximum and the associated magnetic field is maximum. A brief time later, generator potential reverses, and the condition shown in view B recurs.

Note: The electric field (E field) and the electrostatic field (E field) are the same. The terms are used interchangeably throughout this text.

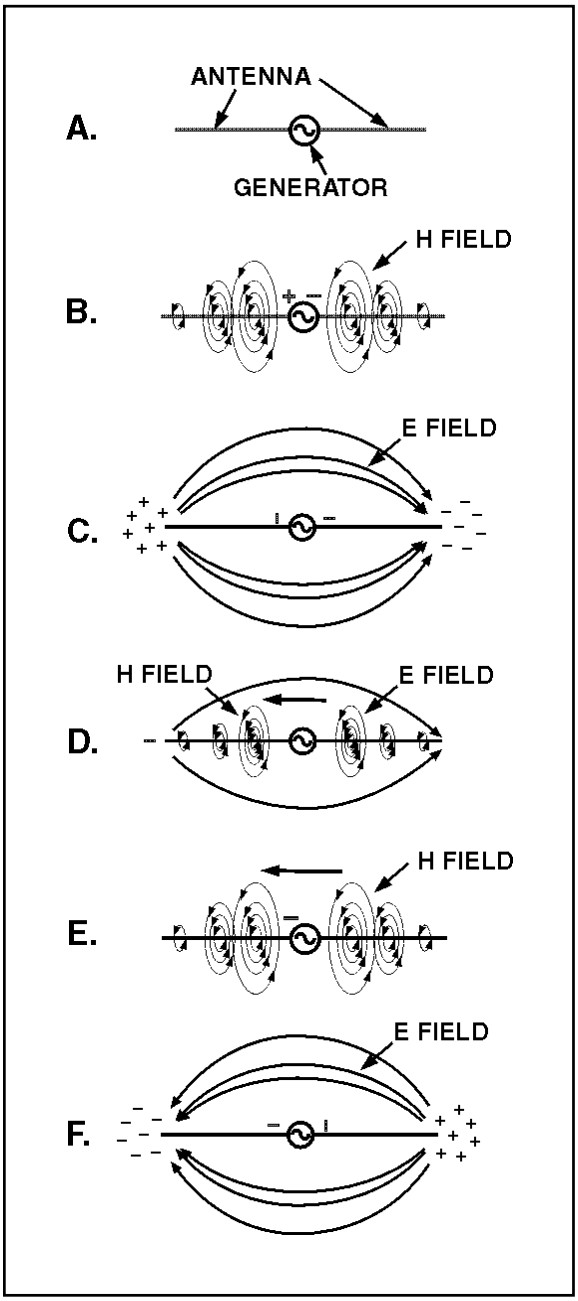

Figure 2-1. Induction Field about an Antenna

2-7. The graph shown in figure 2-2 shows the relationship between the magnetic (H) field and the electric (E) field plotted against time. Note that the two fields are 90 degrees out of phase with each other. If you compare the graph in figure 2-2 with figure 2-1, you will notice that the two fields around the antenna are displaced 90 degrees from each other in space. (The H field exists in a plane perpendicular to the antenna. The E field exists in a plane parallel with the antenna, as shown in figure 2-1.)

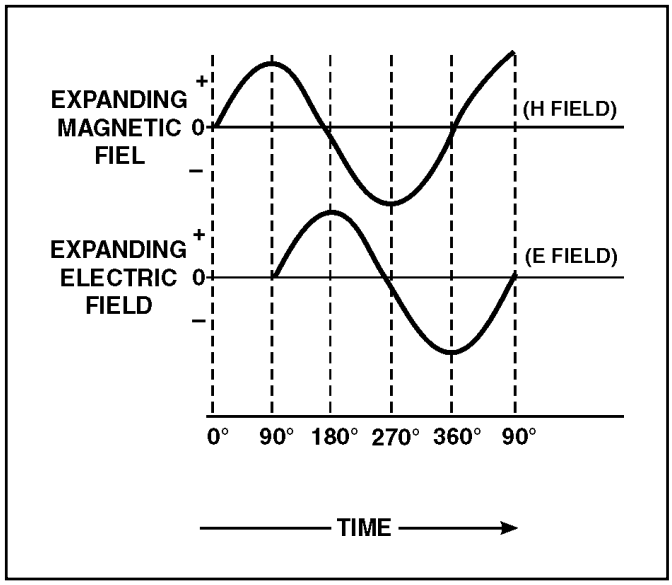

Figure 2-2. Phase Relationship of Induction Field Components

2-8. All the energy supplied to the induction field is returned to the antenna by the collapsing E and H fields. No energy from the induction field is radiated from the antenna. Therefore, the induction field is considered a local field and plays no part in the transmission of electromagnetic energy. The induction field represents only the stored energy in the antenna and is responsible only for the resonant effects that the antenna reflects to the generator.

RADIATION FIELD

2-9. The E and H fields that are set up in the transfer of energy through space are known collectively as the radiation field. This radiation field is responsible for electromagnetic radiation from the antenna. The radiation field decreases as the distance from the antenna is increased. Because the decrease is linear, the radiation field reaches great distances from the antenna.

2-10. Let us look at a half-wave antenna to illustrate how this radiation actually takes place. Simply stated, a half-wave antenna is one that has an electrical length equal to half the wavelength of the signal being transmitted. Assume, for example, that a transmitter is operating at 30 megahertz. If a half-wave antenna is used with the transmitter, the antenna's electrical length would have to be at least 16 feet long. (The formula used to compute the electrical length of an antenna is explained in chapter 4.) When power is delivered to the half-wave antenna, both an induction field and a radiation field are set up by the fluctuating energy. At the antenna, the intensities of these fields are proportional to the amount of power delivered to the antenna from a source such as a transmitter. At a short distance from the antenna and beyond, only the radiation field exists. This radiation field is made up of an electric component and a magnetic component at right angles to each other in space and varying together in intensity.

2-11. With a high-frequency generator (a transmitter) connected to the antenna, the induction field is produced as described in the previous section. However, the generator potential reverses before the electrostatic field has had time to collapse completely. The reversed generator potential neutralizes the remaining antenna charges, leaving a resultant E field in space.

2-12. Figure 2-3 is a simple picture of an E field detaching itself from an antenna. (The H field is not considered in this example, although it is present.) In view A, the voltage is maximum and the electric field has maximum intensity. The lines of force begin at the end of the antenna that is positively charged and extend to the end of the antenna that is negatively charged. Note that the outer E lines are stretched away from the inner lines. This is because of the repelling force that takes place between lines of force in the same direction. As the voltage drops (view B), the separated charges come together, and the ends of the lines move toward the center of the antenna. However, because lines of force in the same direction repel each other, the centers of the lines are still being held out.

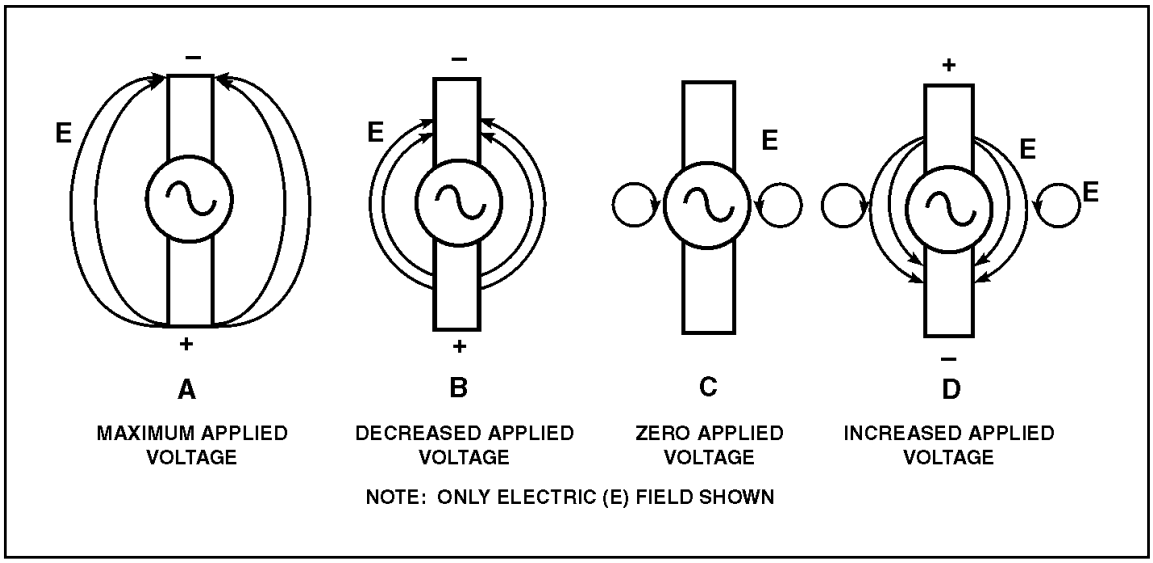

Figure 2-3. Radiation from an Antenna

2-13. As the voltage approaches zero (view B), some of the lines collapse back into the antenna. At the same time, the ends of other lines begin to come together to form a complete loop. Notice the direction of these lines of force next to the antenna in view C. At this point the voltage on the antenna is zero. As the charge starts to build up in the opposite direction (view D), electric lines of force again begin at the positive end of the antenna and stretch to the negative end of the antenna. These lines of force, being in the same direction as the sides of the closed loops next to the antenna, repel the closed loops and force them out into space at the speed of light. As these loops travel through space, they generate a magnetic field in phase with them.

2-14. Because each successive E field is generated with a polarity that is opposite the preceding E field (that is, the lines of force are opposite), an oscillating electric field is produced along the path of travel. When an electric field oscillates, a magnetic field having an intensity that varies directly with

that of the E field is produced. The variations in magnetic field intensity, in turn, produce another E field. Thus, the two varying fields sustain each other, resulting in electromagnetic wave propagation.

2-15. During this radiation process, the E and H fields are in phase in time but physically displaced 90 degrees in space. Thus, the varying magnetic field produces a varying electric field; and the varying electric field, in turn, sustains the varying magnetic field. Each field supports the other, and neither can be propagated by itself. Figure 2-4 shows a comparison between the induction field and the radiation field.

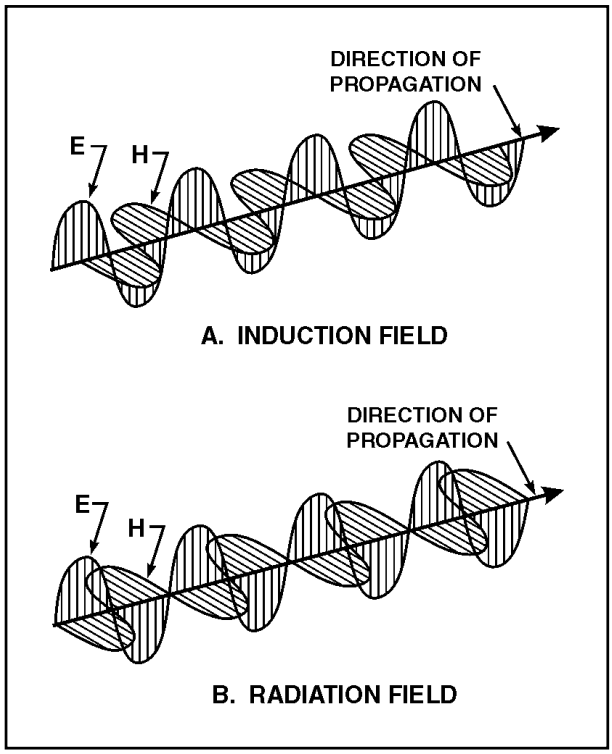

Figure 2-4. E and H Components of Induction and Radiation Fields

RADIO WAVES

2-16. An energy wave generated by a transmitter is called a radio wave. The radio wave radiated into space by the transmitting antenna is a very complex form of energy containing both electric and magnetic fields. Because of this combination of fields, radio waves are also referred to as electromagnetic radiation. The discussion that follows explains the earth's atmosphere and its effect on radio waves. All the principles of wave motion that were discussed in chapter 1 also apply to radio waves.

Note. The term radio wave is not limited to communications equipment alone. The term applies to all equipment that generates signals in the form of electromagnetic energy.

CHARACTERISTICS OF RADIO WAVES

2-17. **Shape**. The basic shape of the wave generated by a transmitter is that of a sine wave. The wave radiated out into space, however, may or may not retain the characteristics of the sine wave.

2-18. A sine wave can be one cycle or many cycles. Recall from chapter 1 that the number of cycles of a sine wave that are completed in 1 second is known as the frequency of the sine wave. For example, 60 cycles of ordinary house current occur each second, so house current is said to have a frequency of 60 cycles per second or 60 hertz.

2-19. **Frequency**. The frequencies falling between 3000 hertz (3 kHz) and 300,000,000,000 hertz (300 GHz) are called radio frequencies (abbreviated RF) because they are commonly used in radio communications. This part of the radio frequency spectrum is divided into bands, each band being 10 times higher in frequency than the one immediately below it. This arrangement serves as a convenient way to remember the range of each band. The RF bands are shown in Table 2-1. The usable radio-frequency range is roughly 10 kilohertz to 100 gigahertz.

Table 2-1. Radio Frequency Bands

DESCRIPTION	*ABBREVIATION*	*FREQUENCY*
Very low	VLF	3 to 30 kHz
Low	LF	30 to 300 kHz
Medium	MF	300 to 3000 kHz
High	HF	3 to 30 MHz
Very high	VHF	30 to 300 MHz
Ultrahigh	UHF	300 to 3000 MHz
Superhigh	SHF	3 to 30 GHz
Extremely high	EHF	30 to 300 GHz

2-20. **Harmonics**. Any frequency that is a whole number multiple of a smaller basic frequency is known as a harmonic of that basic frequency. The basic frequency itself is called the first harmonic or, more commonly, the fundamental frequency. A frequency that is twice as great as the fundamental frequency is called the second harmonic; a frequency three times as great is the third harmonic; and so on. For example:

- First harmonic (fundamental frequency) 3000 kHz
- Second harmonic 6000 kHz
- Third harmonic 9000 kHz

2-21. **Period**. The period of a radio wave is simply the amount of time required to complete one full cycle. If a sine wave has a frequency of 2 hertz, each cycle has a duration, or period, of one-half second. If the frequency is 10 hertz, the period of each cycle is one-tenth of a second. Because the frequency of a radio wave is the number of cycles that are completed in one second, you should be able to see that as the frequency of a radio wave increases, its period decreases.

2-22. **Wavelength**. A wavelength is the space occupied by one full cycle of a radio wave at any given instant. Wavelengths are expressed in meters (1 meter is equal to 3.28 feet). You need to have a good understanding of frequency and wavelength to be able to select the proper antenna(s) to use for successful communications. The relationship between frequency, wavelength, and antennas are discussed in chapter 4.

2-23. **Velocity**. The velocity (or speed) of a radio wave radiated into free space by a transmitting antenna is equal to the speed of light, which is 186,000 miles per second or 300,000,000 meters per second. Because of various factors, such as barometric pressure, humidity, and molecular content, radio waves travel inside the earth's atmosphere at a speed slightly less than the speed of light. Normally, in discussions of the velocity of radio waves, the velocity referred to is the speed at which radio waves travel in free space.

2-24. The frequency of a radio wave has nothing to do with its velocity. A 5-megahertz wave travels through space at the same velocity as a 10-megahertz wave. However, the velocity of radio waves is an important factor in making wavelength-to-frequency conversions, the subject of our next discussion.

WAVELENGTH-TO-FREQUENCY CONVERSIONS

2-25. Radio waves are often referred to by their wavelength in meters rather than by frequency. For example, most people have heard commercial radio stations make announcements similar to the following: "Station WXYZ operating on 240 meters." To tune receiving equipment that is calibrated by frequency to such a station, you must first convert the designated wavelength to its equivalent frequency.

2-26. As discussed earlier, a radio wave travels 300,000,000 meters per second (speed of light); therefore, a radio wave of 1 hertz would have traveled a distance (or wavelength) of 300,000,000 meters. Obviously then, if the frequency of the wave is increased to 2 hertz, the wavelength will be cut in half to 150,000,000 meters. This illustrates the principle that the higher the frequency, the shorter the wavelength.

2-27. Wavelength-to-frequency conversions of radio waves are really quite simple because wavelength and frequency are reciprocals: Either one divided into the velocity of a radio wave yields the other. Remember, the formula for wavelength is:

$$\lambda = \frac{v}{f} \quad \text{or} \quad f = \frac{v}{\lambda}$$

Where:

λ = wavelength in meters

v = velocity of radio of radio wave (in Hz, kHz, or MHz)

f = frequency of radio wave (in Hz, kHz, or MHz)

2-28. The wavelength in meters divided into 300,000,000 yields the frequency of a radio wave in hertz. Likewise, the wavelength divided into 300,000 yields the frequency of a radio wave in kilohertz, and the wavelength divided into 300 yields the frequency in megahertz.

2-29. Now, let us apply the formula to determine the frequency to which the receiving equipment must be tuned to receive station WXYZ operating on 240 meters. Radio wave frequencies are normally expressed in kilohertz or megahertz.

2-30. To find the frequency in hertz, use the formula:

$$f = \frac{v}{\lambda}$$

Given:

$v = 300{,}000{,}000$ meters per second

$\lambda = 240$ meters

Solution:

$$f = \frac{300{,}000{,}000 \text{ meters per second}}{240 \text{ meters}}$$

$f = 1{,}250{,}000$ Hz

2-31. To find the frequency in kilohertz, use the formula:

$$f\,(\text{kHz}) = \frac{300{,}000}{\lambda}$$

Given:

$\lambda = 240$ meters

Solution:

$$f\,(\text{kHz}) = \frac{300{,}000}{240 \text{ meters}}$$

$f = 1{,}250$ kHz

2-32. To find the frequency in megahertz, use the formula:

$$f\,(\text{MHz}) = \frac{300}{\lambda}$$

Given:

$\lambda = 240$ meters

Solution:

$$f\,(\text{MHz}) = \frac{300}{240 \text{ meters}}$$

$f = 1.25$ MHz

POLARIZATION

2-33. For maximum absorption of energy from the electromagnetic fields, the receiving antenna must be located in the plane of polarization. This places the conductor of the antenna at right angles to the magnetic lines of force moving through the antenna and parallel to the electric lines, causing maximum induction.

2-34. Normally, the plane of polarization of a radio wave is the plane in which the E field propagates with respect to the earth. If the E field component of the radiated wave travels in a plane perpendicular to the earth's surface (vertical), the radiation is said to be vertically polarized, as shown in figure 2-5, view A. If the E field propagates in a plane parallel to the earth's surface (horizontal), the radiation is said to be horizontally polarized, as shown in view B.

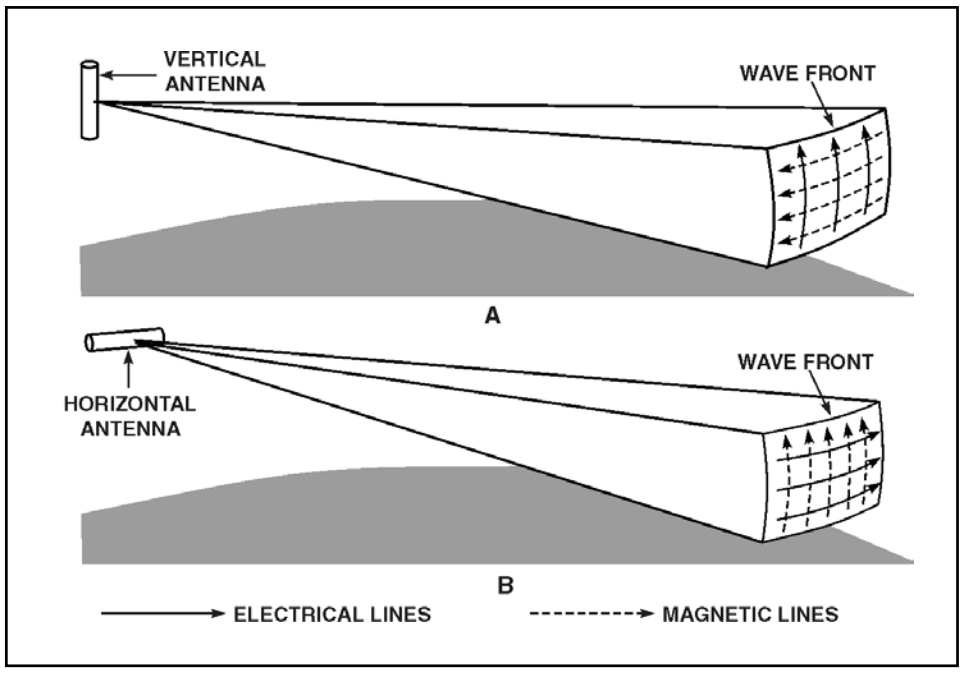

Figure 2-5. Vertical and Horizontal Polarization

2-35. The position of the antenna in space is important because it affects the polarization of the electromagnetic wave. When the transmitting antenna is close to the ground, vertically polarized waves cause greater signal strength along the earth's surface. On the other hand, antennas high above the ground should be horizontally polarized to get the greatest possible signal strength to the earth's surface. Vertically and horizontally polarized antennas are discussed in more detail in chapter 4.

2-36. The radiated energy from an antenna is in the form of an expanding sphere. Any small section of this sphere is perpendicular to the direction the energy travels and is called a wavefront. All energy on a wavefront is in phase. Usually all points on the wavefront are at equal distances from the antenna. The farther the wavefront is from the antenna, the less spherical

the wave appears. At a considerable distance the wavefront can be considered as a plane surface at a right angle to the direction of propagation.

2-37. If you know the directions of the E and H components, you can use the "right-hand rule" to determine the direction of wave propagation (see figure 2-6). This rule states that if the thumb, forefinger, and middle finger of the right hand are extended so they are mutually perpendicular, the middle finger will point in the direction of wave propagation if the thumb points in the direction of the E field and the forefinger points in the direction of the H field. Because both the E and H fields reverse directions simultaneously, propagation of a particular wavefront is always in the same direction (away from the antenna).

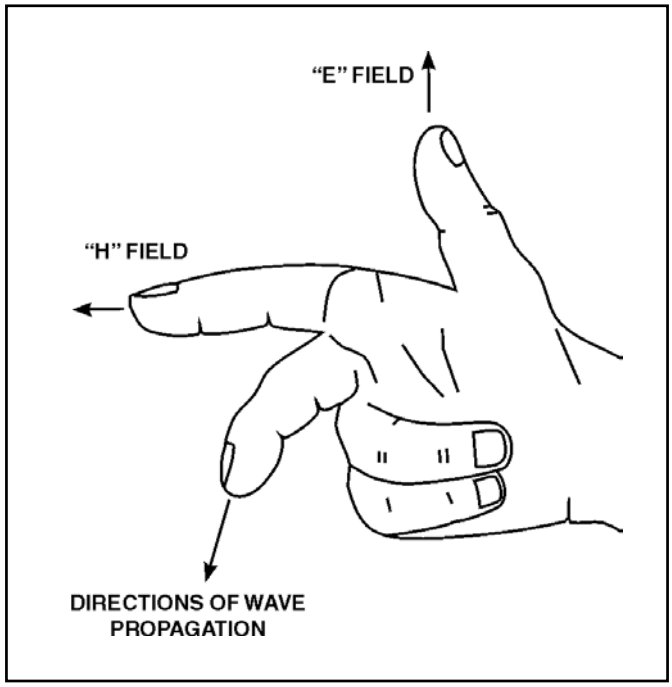

Figure 2-6. Right-Hand Rule for Propagation

ATMOSPHERIC PROPAGATION

2-38. Within the atmosphere, radio waves can be reflected, refracted, and diffracted in the same manner as light and heat waves.

Reflection

2-39. Radio waves may be reflected from various substances or objects they meet during travel between the transmitting and receiving sites. The amount of reflection depends on the reflecting material. Smooth metal surfaces of good electrical conductivity are efficient reflectors of radio waves. The surface of the earth itself is a fairly good reflector. The radio wave is not reflected from a single point on the reflector but rather from an area on its surface. The size of the area required for reflection to take place depends on the wavelength of the radio wave and the angle at which the wave strikes the reflecting substance.

2-40. When radio waves are reflected from flat surfaces, a phase shift in the alternations of the wave occurs. Figure 2-7 shows two radio waves being reflected from the earth's surface. Notice that the positive and negative alternations of radio waves (A) and (B) are in phase with each other in their paths toward the earth's surface. After reflection takes place, however, the waves are approximately 180 degrees out of phase. The amount of phase shift that occurs is not constant. It depends on the polarization of the wave and the angle at which the wave strikes the reflecting surface. Radio waves that keep their phase relationships after reflection normally produce a stronger signal at the receiving site. Those that are received out of phase produce a weak or fading signal. The shifting in the phase relationships of reflected radio waves is one of the major reasons for fading. Fading is discussed in more detail later in this chapter.

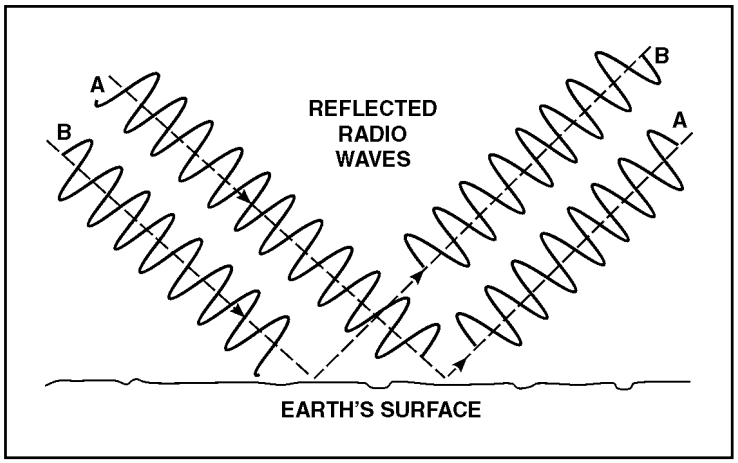

Figure 2-7. Phase Shift of Reflected Radio Waves

Refraction

2-41. Another phenomenon common to most radio waves is the bending of the waves as they move from one medium into another in which the velocity of propagation is different. This bending of the waves is called refraction. For example, suppose you are driving down a smoothly paved road at a constant speed and suddenly one wheel goes off onto the soft shoulder. The car tends to veer off to one side. The change of medium, from hard surface to soft shoulder, causes a change in speed or velocity. The tendency is for the car to change direction. This same principle applies to radio waves as changes occur in the medium through which they are passing. As an example, the radio wave shown in figure 2-8 is traveling through the earth's atmosphere at a constant speed. As the wave enters the dense layer of electrically charged ions, the part of the wave that enters the new medium first travels faster than the parts of the wave that have not yet entered the new medium. This abrupt increase in velocity of the upper part of the wave causes the wave to bend back toward the earth. This bending, or change of direction, is always toward the medium that has the lower velocity of propagation.

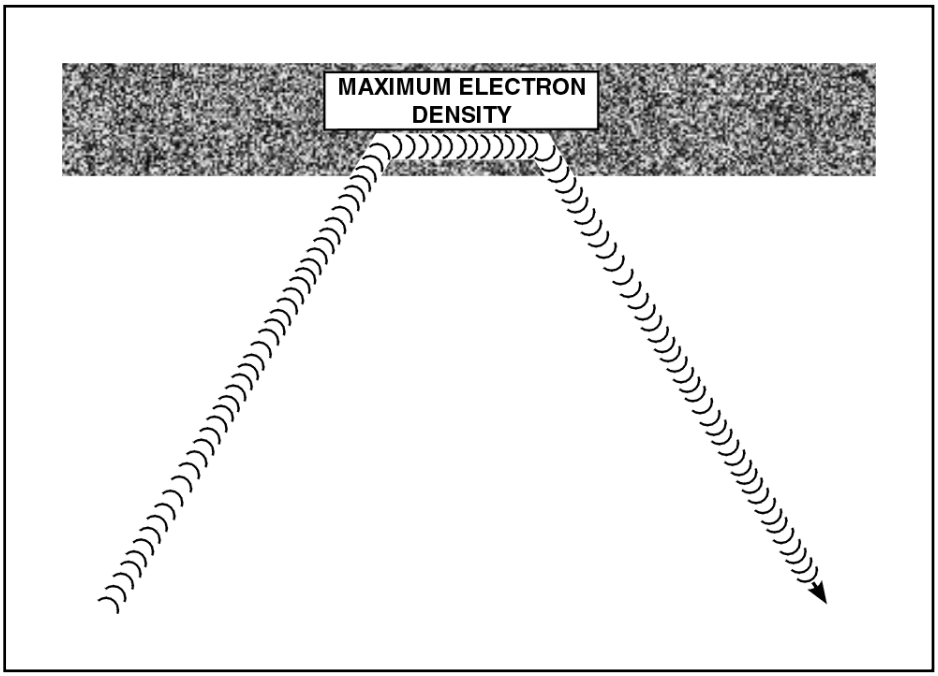

Figure 2-8. Radio Wave Refraction

2-42. Radio waves passing through the atmosphere are affected by certain factors, such as temperature, pressure, humidity, and density. These factors can cause the radio waves to be refracted. This effect is discussed in greater detail later in this chapter.

Diffraction

2-43. A radio wave that meets an obstacle has a natural tendency to bend around the obstacle, as illustrated in figure 2-9. The bending, called diffraction, results in a change of direction of part of the wave energy from the normal line-of-sight path. This change makes it possible to receive energy around the edges of an obstacle as shown in figure 2-9, view A or at some distances below the highest point of an obstruction, as shown in view B. Although diffracted RF energy usually is weak, it can still be detected by a suitable receiver. The principal effect of diffraction extends the radio range beyond the visible horizon. In certain cases, by using high power and very low frequencies, radio waves can be made to encircle the earth by diffraction.

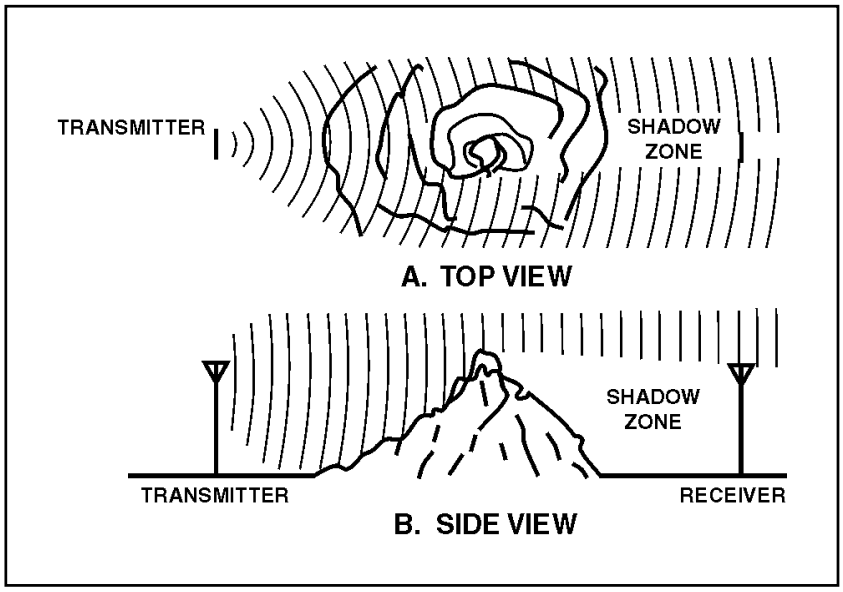

Figure 2-9. Diffraction around an Object

EFFECT OF THE EARTH'S ATMOSPHERE ON RADIO WAVES

2-44. The discussion of electromagnetic wave propagation is concerned mainly with the properties and effects of the medium located between the transmitting antenna and the receiving antenna. While radio waves traveling in free space have little outside influence affecting them, radio waves traveling within the earth's atmosphere are affected by varying conditions. The influence exerted on radio waves by the earth's atmosphere adds many new factors to complicate what at first seems to be a relatively simple problem. These complications are because of a lack of uniformity within the earth's atmosphere. Atmospheric conditions vary with changes in height, geographical location, and even with changes in time (day, night, season, and year). Knowledge of the composition of the earth's atmosphere is extremely important for understanding wave propagation.

2-45. The earth's atmosphere is divided into three separate regions, or layers. They are the troposphere, the stratosphere, and the ionosphere. The layers of the atmosphere are illustrated in figure 2-10.

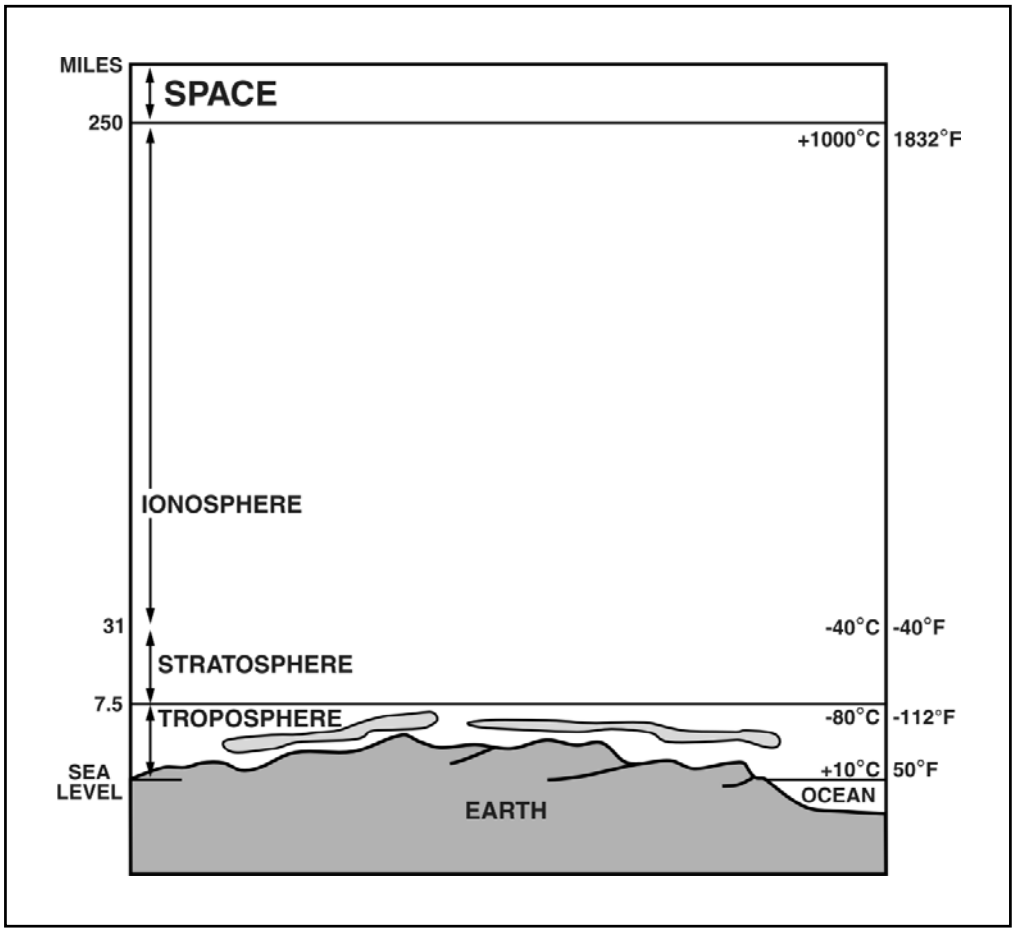

Figure 2-10. Layers of the Earth's Atmosphere

Troposphere

2-46. The troposphere is the portion of the earth's atmosphere that extends from the surface of the earth to a height of about 3.7 miles (6 km) at the North Pole or the South Pole, and 11.2 miles (18 km) at the equator. Virtually all weather phenomena take place in the troposphere. The temperature in this region decreases rapidly with altitude, clouds form, and there may be much turbulence because of variations in temperature, density, and pressure. These conditions have a great effect on the propagation of radio waves, as explained later in this chapter.

Stratosphere

2-47. The stratosphere is located between the troposphere and the ionosphere. The temperature throughout this region is considered to be almost constant and there is little water vapor present. The stratosphere has relatively little effect on radio waves because it is a relatively calm region with little or no temperature changes.

Ionosphere

2-48. The ionosphere extends upward from about 31.1 miles (50 km) to a height of about 250 miles (402 km). It contains four cloud-like layers of electrically charged ions, which enable radio waves to be propagated to great distances around the earth. This is the most important region of the atmosphere for long distance point-to-point communications. This region is discussed in detail later in this chapter.

RADIO WAVE TRANSMISSION PATHS

2-49. There are two principal ways in which electromagnetic (radio) energy travels from a transmitting antenna to a receiving antenna. One way is by ground waves and the other is by sky waves. Ground waves are radio waves that travel near the surface of the earth (surface and space waves). Sky waves are radio waves that are reflected back to Earth from the ionosphere (see figure 2-11).

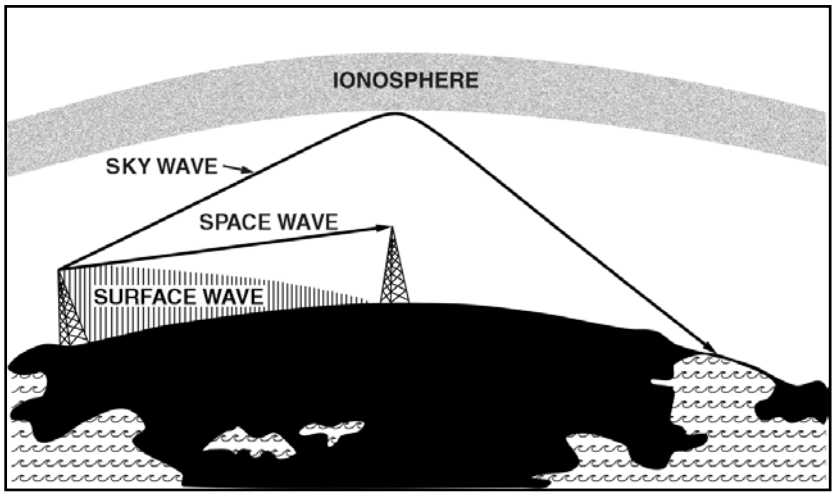

Figure 2-11. Ground Waves and Sky Waves

Ground Waves

2-50. The ground wave is actually composed of two separate component waves. These are known as the surface wave and the space wave (figure 2-11). The determining factor in whether a ground wave component is classified as a space wave or a surface wave is simple. A surface wave travels along the surface of the earth. A space wave travels over the surface.

2-51. **Surface wave**. The surface wave reaches the receiving site by traveling along the surface of the ground as shown in figure 2-12. A surface wave can follow the contours of the earth because of the process of diffraction. When a surface wave meets an object and the dimensions of the object do not exceed its wavelength, the wave tends to curve or bend around the object. The smaller the object, the more pronounced the diffractive action will be.

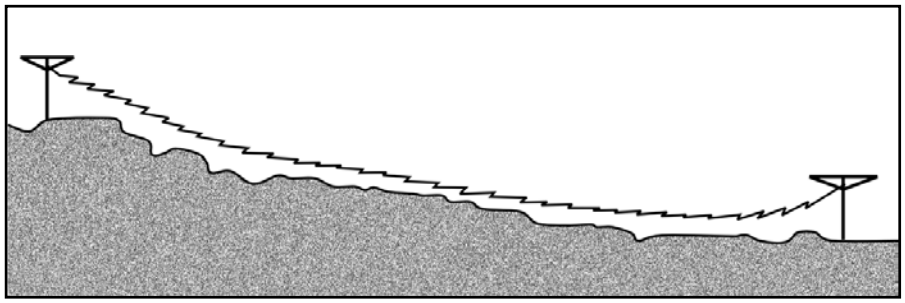

Figure 2-12. Surface Wave Propagation

2-52. As a surface wave passes over the ground, the wave induces a voltage in the earth. The induced voltage takes energy away from the surface wave, thereby weakening, or attenuating, the wave as it moves away from the transmitting antenna. To reduce the attenuation, the amount of induced voltage must be reduced. This is done by using vertically polarized waves that minimize the extent to which the electric field of the wave is in contact with the earth. When a surface wave is horizontally polarized, the electric field of the wave is parallel with the surface of the earth and, therefore, is constantly in contact with it. The wave is then completely attenuated within a short distance from the transmitting site. On the other hand, when the surface wave is vertically polarized, the electric field is perpendicular to the earth and merely dips into and out of the earth's surface. For this reason, vertical polarization is vastly superior to horizontal polarization for surface wave propagation.

2-53. The attenuation that a surface wave undergoes because of induced voltage also depends on the electrical properties of the terrain over which the wave travels. The best type of surface is one that has good electrical conductivity. The better the conductivity, the less the attenuation. Table 2-2 gives the relative conductivity of various Earth surfaces.

Table 2-2. Surface Conductivity

SURFACE	*RELATIVE CONDUCTIVITY*
Sea water	Good
Flat, loamy soil	Fair
Large bodies of fresh water	Fair
Rocky terrain	Poor
Desert	Poor
Jungle	Unusable

2-54. Another major factor in the attenuation of surface waves is frequency. Recall from earlier discussions on wavelength that the higher the frequency of a radio wave, the shorter its wavelength will be. These high frequencies, with their shorter wavelengths, are not normally diffracted but are absorbed by the earth at points relatively close to the transmitting site. You can assume, therefore, that as the frequency of a surface wave is increased, the more rapidly the surface wave will be absorbed, or attenuated, by the earth.

Because of this loss by attenuation, the surface wave is impractical for long-distance transmissions at frequencies above 2 megahertz. On the other hand, when the frequency of a surface wave is low enough to have a very long wavelength, the earth appears to be very small, and diffraction is sufficient for propagation well beyond the horizon. In fact, by lowering the transmitting frequency into the very low frequency (VLF) range and using very high-powered transmitters, the surface wave can be propagated great distances.

2-55. **Space wave**. The space wave follows two distinct paths from the transmitting antenna to the receiving antenna—one through the air directly to the receiving antenna, the other reflected from the ground to the receiving antenna. These paths are illustrated in figure 2-13. The primary or direct path of the space wave is directly from the transmitting antenna to the receiving antenna. So, the receiving antenna must be located within the radio horizon of the transmitting antenna. Because space waves are refracted slightly, even when propagated through the troposphere, the radio horizon is actually about one-third farther than the line-of-sight or natural horizon.

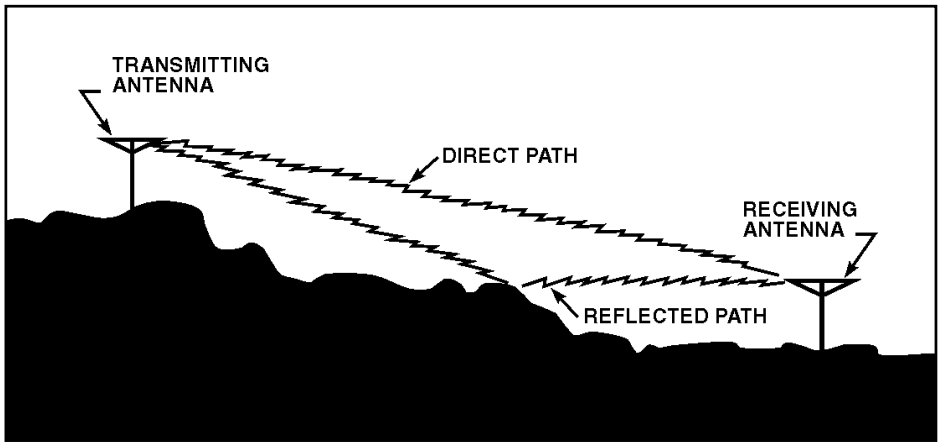

Figure 2-13. Space Wave Propagation

2-56. Although space waves suffer little ground attenuation, they nevertheless are susceptible to fading. This is because space waves actually follow two paths of different lengths (direct path and ground reflected path) to the receiving site and, therefore, may arrive in or out of phase. If these two component waves are received in phase, the result is a reinforced or stronger signal. Likewise, if they are received out of phase, they tend to cancel one another, which results in a weak or fading signal.

Sky Wave

2-57. The sky wave, often called the ionospheric wave, is radiated in an upward direction and returned to Earth at some distant location because of refraction from the ionosphere. This form of propagation is relatively unaffected by the earth's surface and can propagate signals over great distances. Usually the high frequency (HF) band is used for sky wave propagation. The following study of the ionosphere and its effect on sky waves will help you understand the nature of sky wave propagation.

STRUCTURE OF THE IONOSPHERE

2-58. As stated previously, the ionosphere is the region of the atmosphere that extends from about 31.1 miles (50 km) above the surface of the earth to about 250 miles (402 km) above the surface. It is appropriately named the ionosphere because it consists of several layers of electrically charged gas atoms called ions. A process called ionization forms the ions.

Ionization

2-59. Ionization occurs when high-energy ultraviolet light waves from the sun enter the ionospheric region of the atmosphere, strike a gas atom, and literally knock an electron free from its parent atom. A normal atom is electrically neutral because it contains equal numbers of positively charged protons in its nucleus and negatively charged electrons that orbit the nucleus. When an electron is knocked free from the atom, the atom becomes positively charged (called a positive ion) and remains in space along with the free electron, which is negatively charged. This process of upsetting electrical neutrality is known as ionization.

2-60. The free negative electrons subsequently absorb part of the ultraviolet energy, which initially freed them from their atoms. As the ultraviolet light wave continues to produce positive ions and negative electrons, its intensity decreases because of the absorption of energy by the free electrons, and an ionized layer is formed. The rate at which ionization occurs depends on the density of atoms in the atmosphere and the intensity of the ultraviolet light wave, which varies with the activity of the sun.

2-61. Because the atmosphere is bombarded by ultraviolet light waves of different frequencies, several ionized layers are formed at different altitudes. Lower frequency ultraviolet waves penetrate the atmosphere the least; therefore, they produce ionized layers at the higher altitudes. Conversely, ultraviolet waves of higher frequencies penetrate deeper and produce layers at the lower altitudes. An important factor in determining the density of ionized layers is the elevation angle of the sun, which changes frequently. For this reason, the height and thickness of the ionized layers vary, depending on the time of day and even the season of the year.

Recombination

2-62. Recall that the process of ionization involves ultraviolet light waves knocking electrons free from their atoms. A reverse process called recombination occurs when the free electrons and positive ions collide with each other. Because these collisions are inevitable, the positive ions return to their original neutral atom state.

2-63. The recombination process also depends on the time of day. Between the hours of early morning and late afternoon, the rate of ionization exceeds the rate of recombination. During this period, the ionized layers reach their greatest density and exert maximum influence on radio waves. During the late afternoon and early evening hours, however, the rate of recombination exceeds the rate of ionization, and the density of the ionized layers begins to decrease. Throughout the night, density continues to decrease, reaching a low point just before sunrise.

Four Distinct Layers

2-64. The ionosphere is composed of three layers designated D, E, and F, from lowest level to highest level as shown in figure 2-14. The F layer is further divided into two layers designated F1 (the lower layer) and F2 (the higher layer). The presence or absence of these layers in the ionosphere and their height above the earth varies with the position of the sun. At high noon, radiation in the ionosphere directly above a given point is greatest. At night it is minimum. When the radiation is removed, many of the particles that were ionized recombine. The time interval between these conditions finds the position and number of the ionized layers within the ionosphere changing. Because the position of the sun varies daily, monthly, and yearly, with respect to a specified point on the earth, the exact position and number of layers present are extremely difficult to determine. However, the following general statements can be made:

- The D layer ranges from about 30 to 55 miles. Ionization in the D layer is low because it is the lowest region of the ionosphere. This layer has the ability to refract signals of low frequencies. High frequencies pass right through it and are attenuated. After sunset, the D layer disappears because of the rapid recombination of ions.
- The E layer limits are from about 55 to 90 miles. This layer is also known as the Kennelly-Heaviside layer, because these two men were the first to propose its existence. The rate of ionic recombination in this layer is rather rapid after sunset and the layer is almost gone by midnight. This layer has the ability to refract signals as high as 20 megahertz. For this reason, it is valuable for communications in ranges up to about 1500 miles.
- The F layer exists from about 90 to 240 miles. During the daylight hours, the F layer separates into two layers, the F1 and F2 layers. The ionization level in these layers is quite high and varies widely during the day. At noon, this portion of the atmosphere is closest to the sun and the degree of ionization is maximum. Because the atmosphere is rarefied at these heights, recombination occurs slowly after sunset. Therefore, a fairly constant ionized layer is always present. The F layers are responsible for high frequency, long distance transmission.

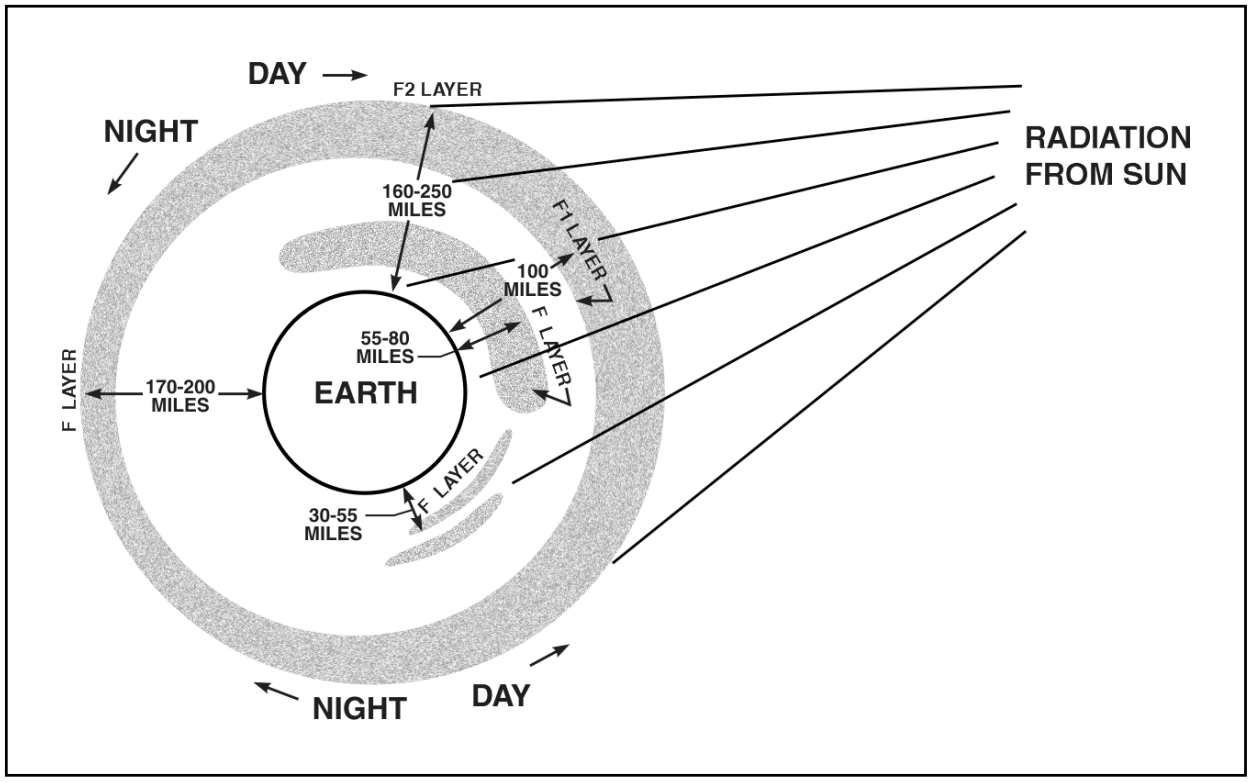

Figure 2-14. Layers of the Ionosphere

REFRACTION IN THE IONOSPHERE

2-65. When a radio wave is transmitted into an ionized layer, refraction, or bending of the wave, occurs. As we discussed earlier, refraction is caused by an abrupt change in the velocity of the upper part of a radio wave as it strikes or enters a new medium. The amount of refraction that occurs depends on three main factors: (1) the density of ionization of the layer, (2) the frequency of the radio wave, and (3) the angle at which the wave enters the layer.

Density of Layer

2-66. Figure 2-15 illustrates the relationship between radio waves and ionization density. Each ionized layer has a central region of relatively dense ionization, which tapers off in intensity both above and below the maximum region. As a radio wave enters a region of increasing ionization, the increase in velocity of the upper part of the wave causes it to be bent back toward the earth. While the wave is in the highly dense center portion of the layer, however, refraction occurs more slowly because the density of ionization is almost uniform. As the wave enters into the upper part of the layer of decreasing ionization, the velocity of the upper part of the wave decreases, and the wave is bent away from the earth. If a wave strikes a thin, very highly ionized layer, the wave may be bent back so rapidly that it appears to have been reflected instead of refracted back to Earth. To reflect a radio wave, the highly ionized layer must be approximately no thicker than one wavelength of the radio wave. Because the ionized layers are often several miles thick, ionospheric reflection is more likely to occur at long wavelengths (low frequencies).

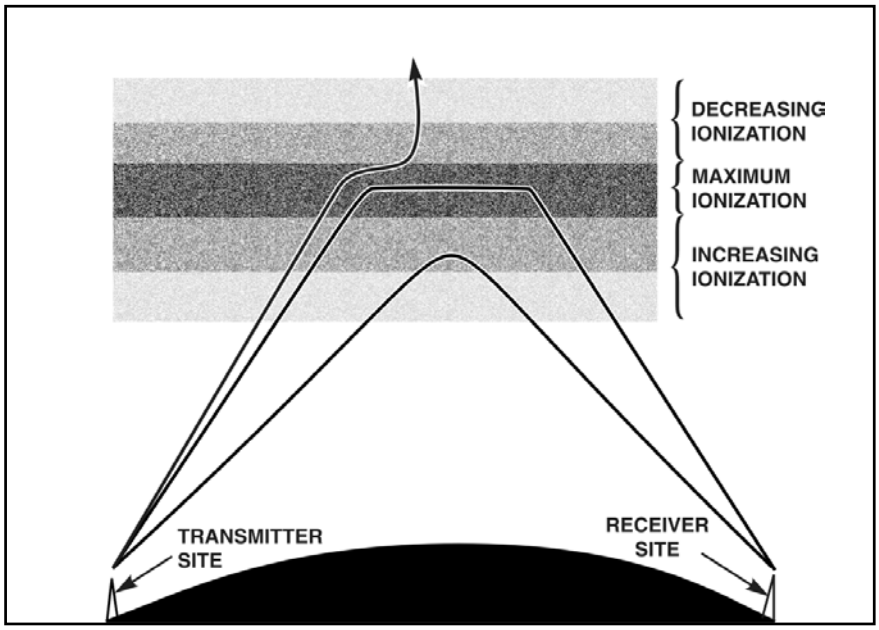

Figure 2-15. Effects of Ionospheric Density on Radio Waves

Frequency

2-67. For any given time, each ionospheric layer has a maximum frequency at which radio waves can be transmitted vertically and refracted back to Earth. This frequency is known as the critical frequency. It is a term that you will hear frequently in any discussion of radio wave propagation. Radio waves transmitted at frequencies higher than the critical frequency of a given layer will pass through the layer and be lost in space; but if these same waves enter an upper layer with a higher critical frequency, they will be refracted back to Earth. Radio waves of frequencies lower than the critical frequency will also be refracted back to Earth unless they are absorbed or have been refracted from a lower layer. The lower the frequency of a radio wave, the more rapidly the wave is refracted by a given degree of ionization. Figure 2-16 shows three separate waves of different frequencies entering an ionospheric layer at the same angle. Notice that the 5-megahertz wave is refracted quite sharply. The 20-megahertz wave is refracted less sharply and returned to Earth at a greater distance. The 100-megahertz wave is obviously greater than the critical frequency for that ionized layer and, therefore, is not refracted but is passed into space.

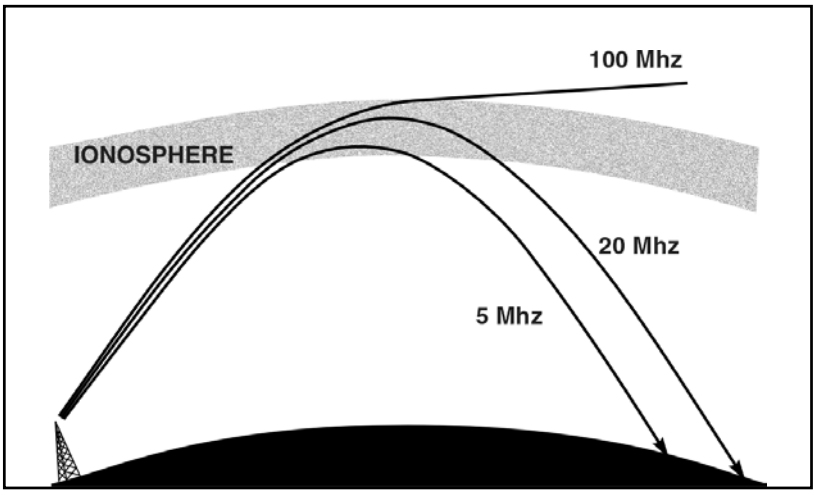

Figure 2-16. Frequency Versus Refraction and Distance

Angle of Incidence

2-68. The rate at which a wave of a given frequency is refracted by an ionized layer depends on the angle at which the wave enters the layer. Figure 2-17 shows three radio waves of the same frequency entering a layer at different angles. The angle at which wave A strikes the layer is too nearly vertical for the wave to be refracted to Earth. As the wave enters the layer, it is bent slightly but passes through the layer and is lost. When the wave is reduced to an angle that is less than vertical (wave B), it strikes the layer and is refracted back to Earth. The angle made by wave B is called the critical angle for that particular frequency. Any wave that leaves the antenna at an angle greater than the critical angle will penetrate the ionospheric layer for that frequency and then be lost in space. Wave C strikes the ionosphere at the smallest angle at which the wave can be refracted and still return to Earth. At any smaller angle, the wave will be refracted but will not return to Earth.

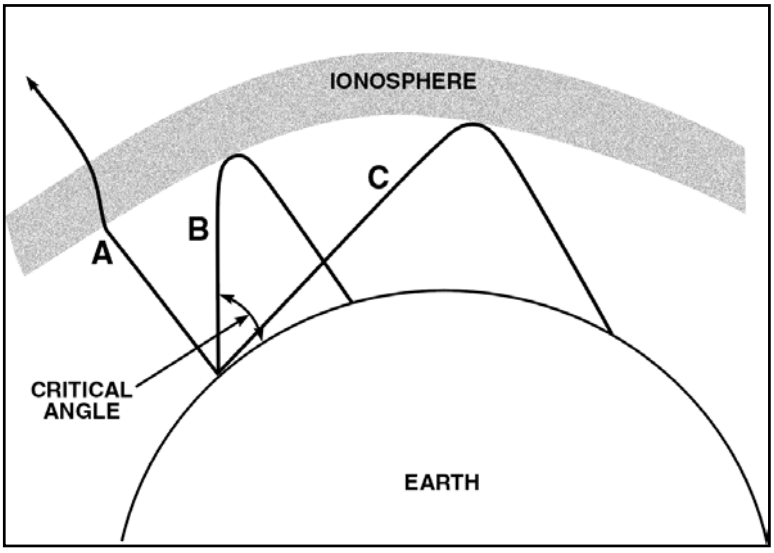

Figure 2-17. Different Incident Angles of Radio Waves

2-69. As the frequency of the radio wave is increased, the critical angle must be reduced for refraction to occur. This point is illustrated in figure 2-18. The 2-megahertz wave strikes the layer at the critical angle for that frequency and is refracted back to Earth. Although the 5-megahertz wave (broken line) strikes the ionosphere at a lesser angle, it nevertheless penetrates the layer and is lost. As the angle is lowered from the vertical, however, a critical angle for the 5-megahertz wave is reached, and the wave is then refracted to Earth.

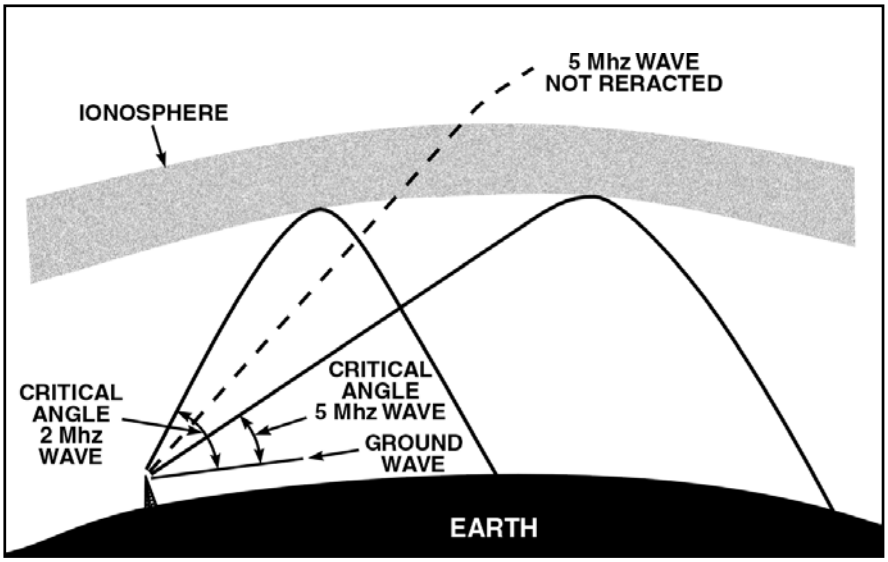

Figure 2-18. Effects of Frequency on the Critical Angle

Skip Distance/Skip Zone

2-70. In figure 2-19, note the relationship between the sky wave skip distance, the skip zone, and the ground wave coverage. The skip distance is the distance from the transmitter to the point where the sky wave is first returned to Earth. The size of the skip distance depends on the frequency of the wave, the angle of incidence, and the degree of ionization present.

2-71. The skip zone is a zone of silence between the point where the ground wave becomes too weak for reception and the point at which the sky wave is first returned to Earth. The size of the skip zone depends on the extent of the ground wave coverage and the skip distance. When the ground wave coverage is great enough or the skip distance is short enough that no zone of silence occurs, there is no skip zone.

2-72. Occasionally, the first sky wave will return to Earth within the range of the ground wave. If the sky wave and ground wave are nearly of equal intensity, the sky wave alternately reinforces and cancels the ground wave, causing severe fading. This fading is caused by the phase difference between the two waves, a result of the longer path traveled by the sky wave.

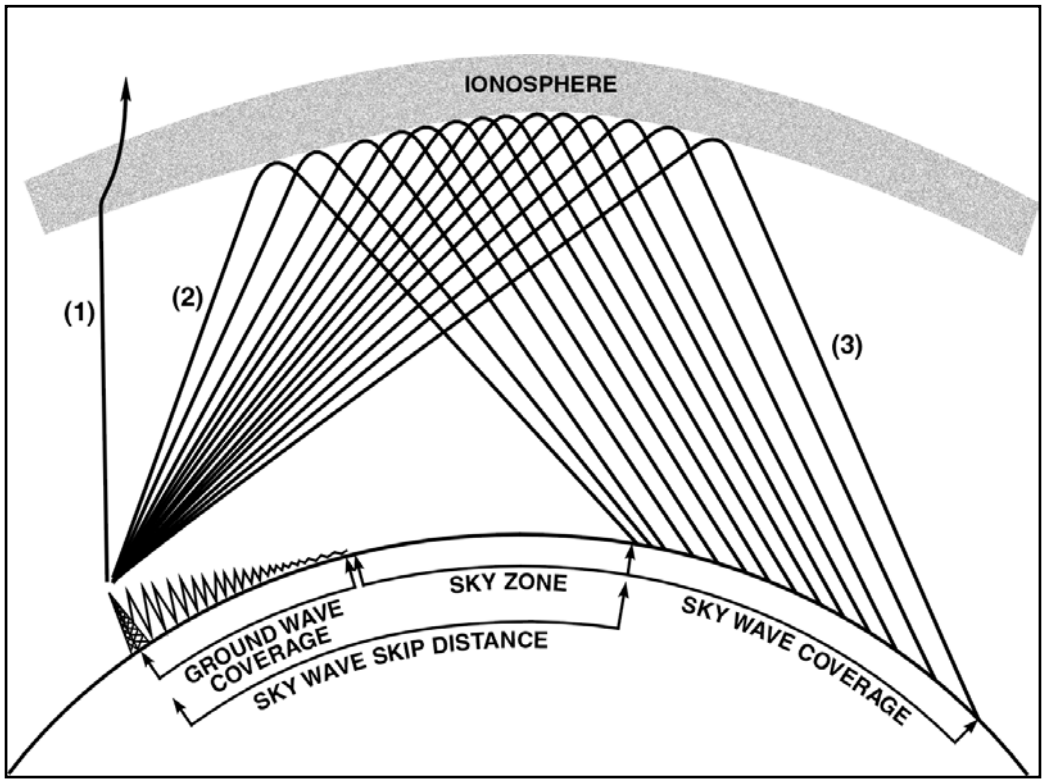

Figure 2-19. Relationship between Skip Zone, Skip Distance, and Ground Wave

Propagation Paths

2-73. The path that a refracted wave follows to the receiver depends on the angle at which the wave strikes the ionosphere. You should remember, however, that the RF energy radiated by a transmitting antenna spreads out with distance. The energy therefore strikes the ionosphere at many different angles rather than a single angle.

2-74. After the RF energy of a given frequency enters an ionospheric region, the paths that this energy might follow are many. It may reach the receiving antenna via two or more paths through a single layer. It may also, reach the receiving antenna over a path involving more than one layer, by multiple hops between the ionosphere and Earth, or by any combination of these paths.

2-75. Figure 2-20 shows how radio waves may reach a receiver via several paths through one layer. The various angles at which RF energy strikes the layer are represented by dark lines and designated as rays 1 through 6.

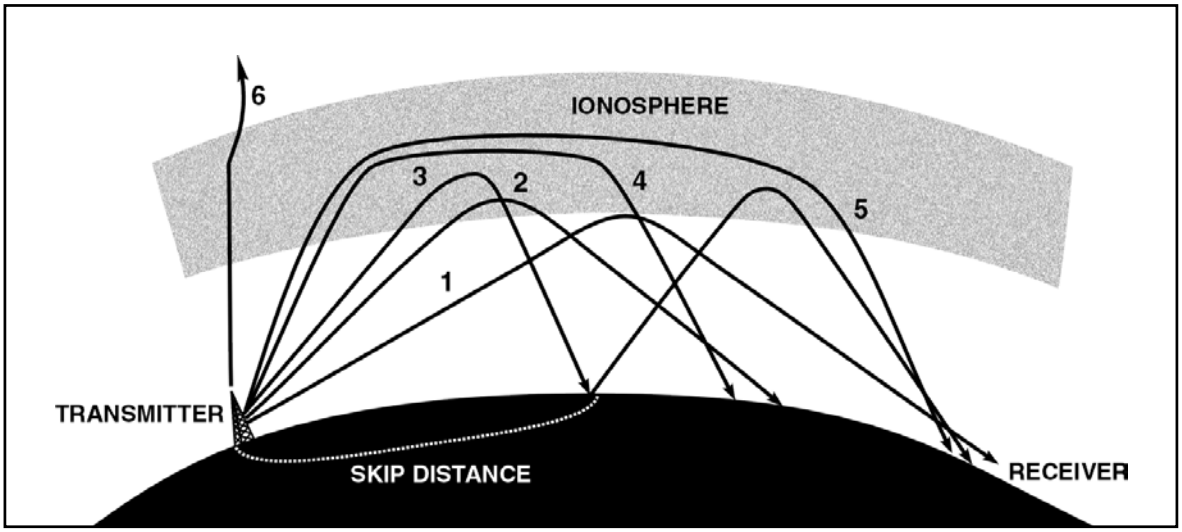

Figure 2-20. Ray Paths for a Fixed Frequency with Varying Angles of Incidence

2-76. When the angle is relatively low with respect to the horizon (ray 1), there is only slight penetration of the layer and the propagation path is long. When the angle of incidence is increased (rays 2 and 3), the rays penetrate deeper into the layer but the range of these rays decreases. When a certain angle is reached (ray 3), the penetration of the layer and rate of refraction are such that the ray is first returned to Earth at a minimal distance from the transmitter. Notice, however, that ray 3 still manages to reach the receiving site on its second refraction (called a hop) from the ionospheric layer.

2-77. As the angle is increased still more (rays 4 and 5), the RF energy penetrates the central area of maximum ionization of the layer. These rays are refracted rather slowly and are eventually returned to Earth at great distances. As the angle approaches vertical incidence (ray 6), the ray is not returned at all, but passes on through the layer.

ABSORPTION IN THE IONOSPHERE

2-78. Many factors affect a radio wave in its path between the transmitting and receiving sites. The factor that has the greatest adverse effect on radio waves is absorption. Absorption results in the loss of energy of a radio wave and has a pronounced effect on both the strength of received signals and the ability to communicate over long distances.

2-79. As discussed previously in the section on ground waves, surface waves suffer most of their absorption losses because of ground-induced voltage. Sky waves, on the other hand, suffer most of their absorption losses because of conditions in the ionosphere. Note that some absorption of sky waves may also occur at lower atmospheric levels because of the presence of water and water vapor. However, this becomes important only at frequencies above 10,000 megahertz.

2-80. Most ionospheric absorption occurs in the lower regions of the ionosphere where ionization density is greatest. As a radio wave passes into the ionosphere, it loses some of its energy to the free electrons and ions. If these high-energy free electrons and ions do not collide with gas molecules of

low energy, most of the energy lost by the radio wave is reconverted into electromagnetic energy, and the wave continues to be propagated with little change in intensity. However, if the high-energy free electrons and ions do collide with other particles, much of this energy is lost, resulting in absorption of the energy from the wave. Because absorption of energy depends on collision of the particles, the greater the density of the ionized layer, the greater the probability of collisions; therefore, the greater the absorption. The highly dense D and E layers provide the greatest absorption of radio waves.

2-81. Because the amount of absorption of the sky wave depends on the density of the ionosphere, which varies with seasonal and daily conditions, it is impossible to express a fixed relationship between distance and signal strength for ionospheric propagation. Under certain conditions, the absorption of energy is so great that communicating over any distance beyond the line of sight is difficult.

FADING

2-82. The most troublesome and frustrating problem in receiving radio signals is variations in signal strength, most commonly known as fading. There are several conditions that can produce fading. When a radio wave is refracted by the ionosphere or reflected from the earth's surface, random changes in the polarization of the wave may occur. Vertically and horizontally mounted receiving antennas are designed to receive vertically and horizontally polarized waves, respectively. Therefore, changes in polarization cause changes in the received signal level because of the inability of the antenna to adjust to the polarization changes.

2-83. Fading also results from absorption of the RF energy in the ionosphere. Absorption fading occurs for a longer period than other types of fading, because absorption takes place slowly. Usually, however, fading on ionospheric circuits is mainly a result of multipath propagation.

Multipath Fading

2-84. Multipath is simply a term used to describe the multiple paths a radio wave may follow between transmitter and receiver. Such propagation paths include the ground wave, ionospheric refraction, reradiation by the ionospheric layers, reflection from the earth's surface or from more than one ionospheric layer, and others. Figure 2-21 shows a few of the paths that a signal can travel between two sites in a typical circuit. One path, XYZ, is the basic ground wave. Another path, XEA, refracts the wave at the E layer and passes it on to the receiver at A. Still another path, XFZFA, results from a greater angle of incidence and two refractions from the F layer. At point Z, the received signal is a combination of the ground wave and the sky wave. These two signals having traveled different paths arrive at point Z at different times. Thus, the arriving waves may or may not be in phase with each other. Radio waves that are received in phase reinforce each other and produce a stronger signal at the receiving site. Conversely, those that are received out of phase produce a weak or fading signal. Small alternations in the transmission path may change the phase relationship of the two signals, causing periodic fading. This condition occurs at point A. At this point, the double-hop F layer signal may be in or out of phase with the signal arriving from the E layer.

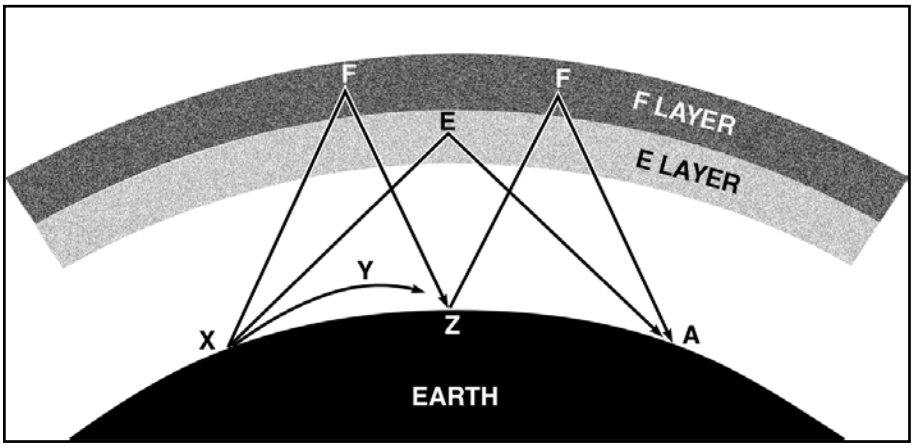

Figure 2-21. Multipath Transmission

2-85. Multipath fading may be minimized by practices called space diversity and frequency diversity. In space diversity, two or more receiving antennas are spaced some distance apart. Fading does not occur simultaneously at both antennas; therefore, enough output is almost always available from one of the antennas to provide a useful signal. In frequency diversity, two transmitters and two receivers are used, each pair tuned to a different frequency, with the same information being transmitted simultaneously over both frequencies. One of the two receivers will almost always provide a useful signal.

Selective Fading

2-86. Fading resulting from multipath propagation varies by frequency because each frequency arrives at the receiving point via a different radio path. When a wide band of frequencies is transmitted simultaneously, each frequency will vary in the amount of fading. This variation is called selective fading. When selective fading occurs, all frequencies of the transmitted signal do not retain their original phases and relative amplitudes. This fading causes severe distortion of the signal and limits the total signal transmitted.

TRANSMISSION LOSSES

2-87. All radio waves propagated over ionospheric paths undergo energy losses before arriving at the receiving site. As discussed earlier, absorption in the ionosphere and lower atmospheric levels account for a large part of these energy losses. There are two other types of losses that also significantly affect the ionospheric propagation of radio waves. These losses are known as ground reflection loss and freespace loss. The combined effects of absorption, ground reflection loss, and freespace loss account for most of the energy losses of radio transmissions propagated by the ionosphere.

Ground Reflection Loss

2-88. When propagation is accomplished via multihop refraction, RF energy is lost each time the radio wave is reflected from the earth's surface. The amount of energy lost depends on the frequency of the wave, the angle of incidence, ground irregularities, and the electrical conductivity of the point of reflection.

Freespace Loss

2-89. Normally, the major loss of energy is because of the spreading out of the wavefront as it travels away from the transmitter. As the distance increases, the area of the wavefront spreads out, much like the beam of a flashlight. This means the amount of energy contained within any unit of area on the wavefront decreases as distance increases. By the time the energy arrives at the receiving antenna, the wavefront is so spread out that the receiving antenna extends into only a very small fraction of the wavefront, as illustrated in figure 2-22.

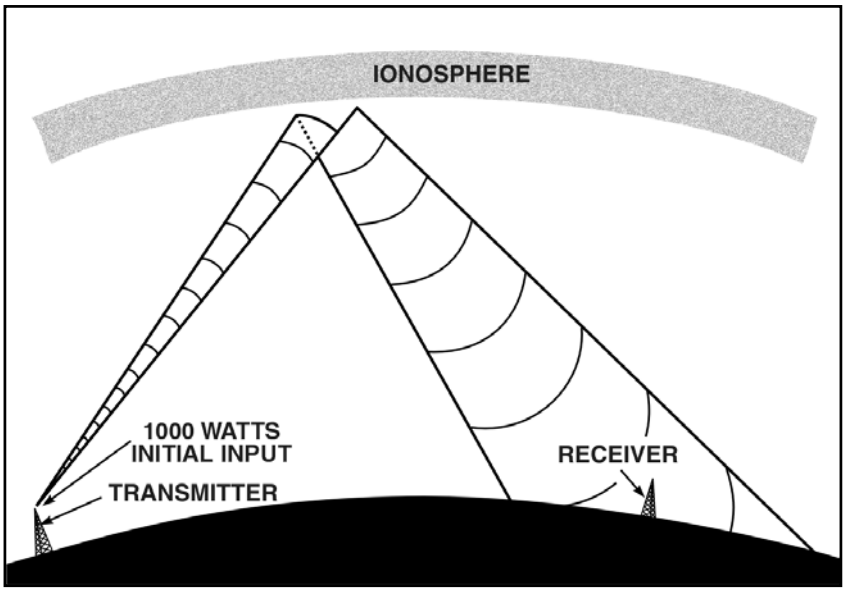

Figure 2-22. Freespace Loss Principle

ELECTROMAGNETIC INTERFERENCE (EMI)

2-90. The transmission losses just discussed are not the only factors that interfere with communications. An additional factor that can interfere with radio communications is the presence of electromagnetic interference (EMI). This interference can result in annoying or impossible operating conditions. Sources of EMI are both man-made and natural.

Man-Made Interference

2-91. Man-made interference may come from several sources. Some of these sources, such as oscillators, communications transmitters, and radio transmitters, may be specifically designed to generate radio frequency energy. Some electrical devices also generate radio frequency energy, although they are not specifically designed for this purpose. Examples are ignition systems, generators, motors, switches, relays, and voltage regulators. The intensity of man-made interference may vary throughout the day and drop off to a low level at night when many of these sources are not being used. Man-made interference may be a critical limiting factor at radio receiving sites located near industrial areas.

Natural Interference

2-92. Natural interference refers to the static that you often hear when listening to a radio. This interference is generated by natural phenomena, such as thunderstorms, snowstorms, cosmic sources, and the sun. The energy released by these sources is transmitted to the receiving site in roughly the same manner as radio waves. As a result, when ionospheric conditions are favorable for the long distance propagation of radio waves, they are likewise favorable for the propagation of natural interference. Natural interference is very erratic, particularly in the HF band, but generally decreases as the operating frequency is increased and wider bandwidths are used. There is little natural interference above 30 megahertz.

Control of EMI

2-93. Electromagnetic interference can be reduced or eliminated by using various suppression techniques. The amount of EMI that is produced by a radio transmitter can be controlled by cutting transmitting antennas to the correct frequency, limiting bandwidth, and using electronic filtering networks and metallic shielding.

2-94. Radiated EMI during transmission can be controlled by the physical separation of the transmitting and receiving antennas, the use of directional antennas, and limiting antenna bandwidth.

VARIATIONS IN THE IONOSPHERE

2-95. Because the existence of the ionosphere is directly related to radiations emitted from the sun, the movement of the earth about the sun or changes in the sun's activity will result in variations in the ionosphere. These variations are of two general types:

- Those that are more or less regular and occur in cycles and, therefore, can be predicted in advance with reasonable accuracy.
- Those that are irregular as a result of abnormal behavior of the sun and, therefore, cannot be predicted in advance. Both regular and irregular variations have important effects on radio wave propagation.

Regular Variations

2-96. The regular variations that affect the extent of ionization in the ionosphere can be divided into four main classes: daily, seasonal, 11-year, and 27-day variations.

2-97. **Daily**. Daily variations in the ionosphere are a result of the 24-hour rotation of the earth about its axis. Daily variations of the different layers (figure 2-14) are summarized as follows:

- The D layer reflects VLF waves, is important for long range VLF communications, refracts LF and MF waves for short-range communications, absorbs HF waves, has little effect on VHF and above, and disappears at night.
- In the E layer, ionization depends on the angle of the sun. The E layer refracts HF waves during the day up to 20 megahertz to distances of about 1200 miles. Ionization is greatly reduced at night.

- The structure and density of the F region depend on the time of day and the angle of the sun. This region consists of one layer during the night and splits into two layers during daylight hours.
- Ionization density of the F1 layer depends on the angle of the sun. Its main effect is to absorb HF waves passing through to the F2 layer.
- The F2 layer is the most important layer for long distance HF communications. It is a particularly variable layer and its height and density change with time of day, season, and sunspot activity.

2-98. **Seasonal**. Seasonal variations are the result of the earth revolving around the sun; the relative position of the sun moves from one hemisphere to the other with changes in seasons. Seasonal variations of the D, E, and F1 layers correspond to the highest angle of the sun; thus the ionization density of these layers is greatest during the summer. The F2 layer, however, does not follow this pattern; its ionization is greatest in winter and least in summer, the reverse of what might be expected. As a result, operating frequencies for F2 layer propagation are higher in the winter than in the summer.

2-99. **Eleven-year sunspot cycle**. One of the most notable phenomena on the surface of the sun is the appearance and disappearance of dark, irregularly shaped areas known as sunspots. The exact nature of sunspots is not known, but scientists believe they are caused by violent eruptions on the sun and are characterized by unusually strong magnetic fields. These sunspots are responsible for variations in the ionization level of the ionosphere. Sunspots can, of course, occur unexpectedly, and the life span of individual sunspots is variable; however, a regular cycle of sunspot activity has also been observed. This cycle has both a minimum and maximum level of sunspot activity that occurs approximately every 11 years.

2-100. During periods of maximum sunspot activity, the ionization density of all layers increases. Because of this, absorption in the D layer increases and the critical frequencies for the E, F1, and F2 layers are higher. At these times, higher operating frequencies must be used for long distance communications.

2-101. **27-Day sunspot cycle**. The number of sunspots in existence at any one time is continually subject to change as some disappear and new ones emerge. As the sun rotates on its own axis, these sunspots are visible at 27-day intervals, the approximate period required for the sun to make one complete rotation.

2-102. The 27-day sunspot cycle causes variations in the ionization density of the layers on a day-to-day basis. The fluctuations in the F2 layer are greater than for any other layer. For this reason, precise predictions on a day-to-day basis of the critical frequency of the F2 layer are not possible. In calculating frequencies for long-distance communications, one must make allowances for the fluctuations of the F2 layer.

Irregular Variations

2-103. Irregular variations in ionospheric conditions also have an important effect on radio wave propagation. Because these variations are irregular and unpredictable, they can drastically affect communications capabilities without any warning. The more common irregular variations are sporadic E, sudden ionospheric disturbances, and ionospheric storms.

2-104. **Sporadic E**. Irregular cloud-like patches of unusually high ionization, called sporadic E, often form at heights near the normal E layer. Exactly what causes this phenomenon is not known, nor can its occurrence be predicted. It is known to vary significantly with latitude, and in the northern latitudes, it appears to be closely related to the aurora borealis or northern lights.

2-105. At times the sporadic E is so thin that radio waves penetrate it easily and are returned to earth by the upper layers. At other times, it extends up to several hundred miles and is heavily ionized.

2-106. These characteristics may be either harmful or helpful to radio wave propagation. For example, sporadic E may blank out the use of higher, more favorable ionospheric layers or cause additional absorption of the radio wave at some frequencies. Also, it can cause additional multipath problems and delay the arrival times of the rays of RF energy.

2-107. On the other hand, the critical frequency of the sporadic E is very high and can be greater than double the critical frequency of the normal ionospheric layers. This condition may permit the long distance transmission of signals at unusually high frequencies. It may also permit short distance communications to locations that would normally be in the skip zone.

2-108. The sporadic E can form and disappear in a short time during either the day or night. However, it usually does not occur at the same time at all transmitting or receiving stations.

2-109. **Sudden ionospheric disturbances**. The most startling of the ionospheric irregularities is known as a sudden ionospheric disturbance (SID). These disturbances may occur without warning and may prevail for any length of time, from a few minutes to several hours. When SID occurs, long distance propagation of HF radio waves is almost totally "blanked out." The immediate effect is that radio operators listening on normal frequencies are inclined to believe that their receivers have gone dead.

2-110. When SID has occurred, examination of the sun has revealed a bright solar eruption. All stations lying wholly, or in part, on the sunward side of the earth are affected. The solar eruption produces an unusually intense burst of ultraviolet light, which is not absorbed by the F2, F1, and E layers, but instead causes a sudden abnormal increase in the ionization density of the D layer. As a result, frequencies above 1 or 2 megahertz are unable to penetrate the D layer and are usually completely absorbed by the layer.

2-111. **Ionospheric storms**. Ionospheric storms are disturbances in the earth's magnetic field. They are associated, in a manner not fully understood, with both solar eruptions and the 27-day intervals, thus corresponding to the rotation of the sun.

2-112. Scientists believe that ionospheric storms result from particle radiation from the sun. Particles radiated from a solar eruption have a slower velocity than ultraviolet light waves produced by the eruption. This would account for the 18-hour or so time difference between a SID and an ionospheric storm. An ionospheric storm that is associated with sunspot activity may begin anytime from 2 days before an active sunspot crosses the central meridian of the sun until four days after it passes the central meridian. At times, however, active sunspots have crossed the central region of the sun without any ionospheric storms occurring. Conversely, ionospheric

storms have occurred when there were no visible spots on the sun and no preceding SID. As you can see, some correlation between ionospheric storms, SID, and sunspot activity is possible, but there are no hard and fast rules. Ionospheric storms can occur suddenly without warning.

2-113. The most prominent effects of ionospheric storms are a turbulent ionosphere and very erratic sky wave propagation. Critical frequencies are lower than normal, particularly for the F2 layer. Ionospheric storms affect the higher F2 layer first, reducing its ion density. Lower layers are not appreciably affected by the storms unless the disturbance is great. The practical effect of ionospheric storms is that the range of frequencies that can be used for communications on a given circuit is much smaller than normal and communications are possible only at the lower working frequencies.

FREQUENCY SELECTION CONSIDERATIONS

2-114. Up to this point, we have covered various factors that control the propagation of radio waves through the ionosphere, such as the structure of the ionosphere, the incidence angle of radio waves, and operating frequencies. There is a very good reason for studying radio wave propagation. One must have a thorough knowledge of radio wave propagation to exercise good judgment when selecting transmitting and receiving antennas and operating frequencies. Selection of a suitable operating frequency (within the bounds of frequency allocations and availability) is of prime importance in maintaining reliable communications.

Note. For successful communications between any two specified locations at any given time of the day, there is a maximum frequency, a lowest frequency, and an optimum frequency that can be used.

Maximum Usable Frequency

2-115. As discussed earlier, the higher the frequency of a radio wave, the lower the rate of refraction by an ionized layer. Therefore, for a given angle of incidence and time of day, there is a maximum frequency that can be used for communications between two given locations. This frequency is known as the maximum usable frequency (MUF).

2-116. Waves at frequencies above the MUF are normally refracted so slowly that they return to Earth beyond the desired location, or pass on through the ionosphere and are lost. You should understand, however, that use of an established MUF certainly does not guarantee successful communications between a transmitting site and a receiving site. Variations in the ionosphere may occur at any time and consequently raise or lower the predetermined MUF. This is particularly true for radio waves being refracted by the highly variable F2 layer. The MUF is highest around noon when ultraviolet light waves from the sun are the most intense. It then drops rather sharply as recombination begins to take place.

Lowest Usable Frequency

2-117. As there is a maximum operating frequency that can be used for communications between two points, there is also a minimum operating frequency. This is known as the lowest usable frequency (LUF). As the frequency of a radio wave is lowered, the rate of refraction increases. So a

wave whose frequency is below the established LUF is refracted back to Earth at a shorter distance than desired, as shown in figure 2-23.

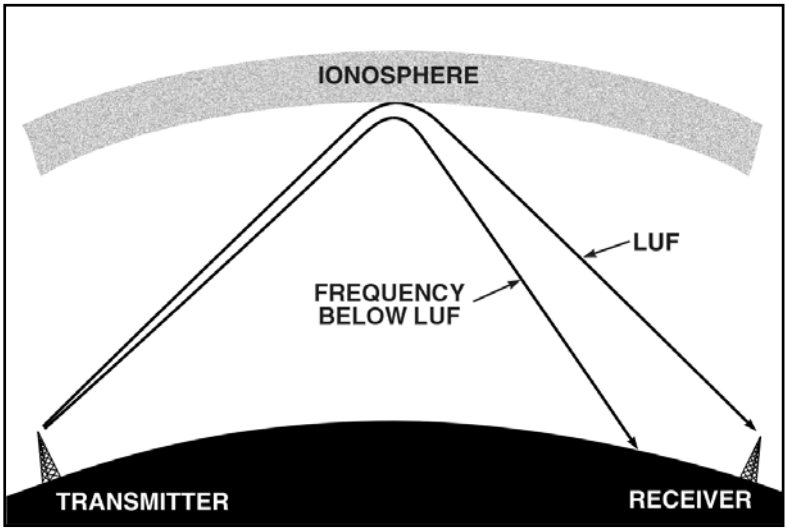

Figure 2-23. Refraction of Frequency below the Lowest Usable Frequency (LUF)

2-118. The transmission path that results from the rate of refraction is not the only factor that determines the LUF. As a frequency is lowered, absorption of the radio wave increases. A wave whose frequency is too low is absorbed to such an extent that it is too weak for reception. Likewise, atmospheric noise is greater at lower frequencies; thus, a low-frequency radio wave may have an unacceptable signal-to-noise ratio.

2-119. For a given angle of incidence and set of ionospheric conditions, the LUF for successful communications between two locations depends on the refraction properties of the ionosphere, absorption considerations, and the amount of atmospheric noise present.

Optimum Working Frequency

2-120. Neither the MUF nor the LUF is a practical operating frequency. While radio waves at the LUF can be refracted back to Earth at the desired location, the signal-to-noise ratio is still much lower than at the higher frequencies, and the probability of multipath propagation is much greater. Operating at or near the MUF can result in frequent signal fading and dropouts when ionospheric variations alter the length of the transmission path.

2-121. The most practical operating frequency is one that you can rely on with the least amount of problems. It should be high enough to avoid the problems of multipath propagation, absorption, and noise encountered at the lower frequencies; but not so high as to result in the adverse effects of rapid changes in the ionosphere.

2-122. A frequency that meets the above criteria has been established and is known as the optimum working frequency. It is abbreviated "FOT" from the initial letters of the French words for optimum working frequency, "frequence optimum de travail." The FOT is roughly about 85 percent of the MUF but the actual percentage varies and may be either considerably more or less than 85 percent.

EFFECTS OF WEATHER ON PROPAGATION

2-123. Weather is an additional factor that affects the propagation of radio waves. In this section, we explain how and to what extent the various weather phenomena affect wave propagation.

2-124. Wind, air temperature, and the water content of the atmosphere can combine in many ways. Certain combinations can cause radio signals to be heard hundreds of miles beyond the ordinary range of radio communications. Conversely, a different combination of factors can cause such attenuation of the signal that it may not be heard even over a normally satisfactory path. Unfortunately, there are no hard and fast rules on the effects of weather on radio transmissions because the weather is extremely complex and subject to frequent change. Therefore, we limit our discussion on the effects of weather on radio waves to general terms.

Precipitation Attenuation

2-125. Calculating the effect of weather on radio wave propagation would be comparatively simple if there were no water or water vapor in the atmosphere. However, some form of water (vapor, liquid, or solid) is always present and must be considered in all calculations. Before we begin discussing the specific effects that individual forms of precipitation (rain, snow, and fog) have on radio waves, you should understand that attenuation because of precipitation is generally proportionate to the frequency and wavelength of the radio wave. For example, rain has a pronounced effect on waves at microwave frequencies. However, rain hardly affects waves with long wavelengths (HF range and below). You can assume, then, that as the wavelength becomes shorter with increases in frequency, precipitation has an increasingly important attenuation effect on radio waves. Conversely, you can assume that as the wavelength becomes longer with decreases in frequency, precipitation has little attenuation effect.

2-126. **Rain**. Attenuation because of raindrops is greater than attenuation because of other forms of precipitation. Attenuation may be caused by absorption, in which the raindrop, acting as a poor dielectric, absorbs power from the radio wave and dissipates the power by heat loss or by scattering (figure 2-24). Raindrops cause greater attenuation by scattering than by absorption at frequencies above 100 megahertz. At frequencies above 6 gigahertz, attenuation by raindrop scatter is even greater.

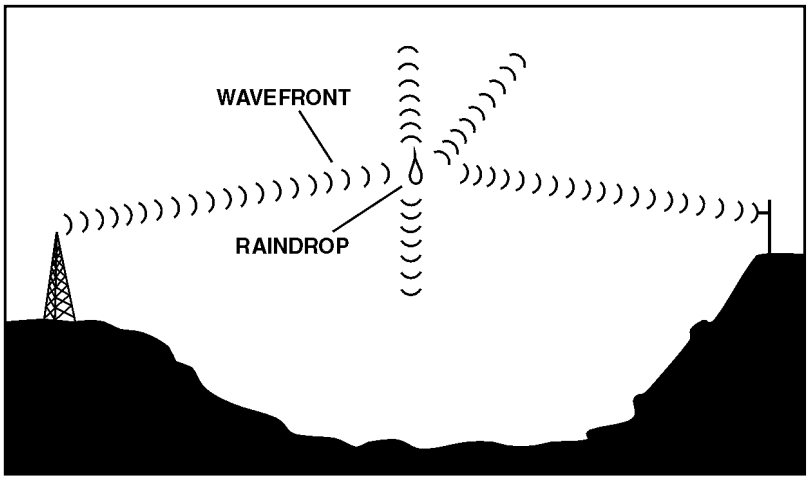

Figure 2-24. RF Energy Losses from Scattering

2-127. **Fog**. In the discussion of attenuation, fog may be considered as another form of rain. Because fog remains suspended in the atmosphere, the attenuation is determined by the quantity of water per unit volume and by the size of the droplets. Attenuation because of fog is of minor importance at frequencies lower than 2 gigahertz. However, fog can cause serious attenuation by absorption at frequencies above 2 gigahertz.

2-128. **Snow**. The scattering effect because of snow is difficult to compute because of irregular sizes and shapes of the flakes. While information on the attenuating effect of snow is limited, scientists assume that attenuation from snow is less than from rain falling at an equal rate. This assumption is borne out by the fact that the density of rain is eight times the density of snow. As a result, rain falling at 1 inch per hour would have more water per cubic inch than snow falling at the same rate.

2-129. **Hail**. Attenuation by hail is determined by the size of the stones and their density. Attenuation of radio waves by scattering because of hailstones is considerably less than by rain.

Temperature Inversion

2-130. Under normal atmospheric conditions, the warmest air is found near the surface of the earth. The air gradually becomes cooler as altitude increases. At times, however, an unusual situation develops in which layers of warm air are formed above layers of cool air. This condition is known as temperature inversion. These temperature inversions cause channels, or ducts, of cool air to be sandwiched between the surface of the earth and a layer of warm air, or between two layers of warm air.

2-131. If a transmitting antenna extends into such a duct of cool air, or if the radio wave enters the duct at a very low angle of incidence, VHF and UHF transmissions may be propagated far beyond normal line-of-sight distances. When ducts are present as a result of temperature inversions, good reception of VHF and UHF television signals from a station located hundreds of miles away is not unusual. These long distances are possible because of the different densities and refractive qualities of warm and cool air. The sudden

change in density when a radio wave enters the warm air above a duct causes the wave to be refracted back toward Earth. When the wave strikes the earth or a warm layer below the duct, it is again reflected or refracted upward and proceeds on through the duct with a multiple-hop type of action. An example of the propagation of radio waves by ducting is shown in figure 2-25.

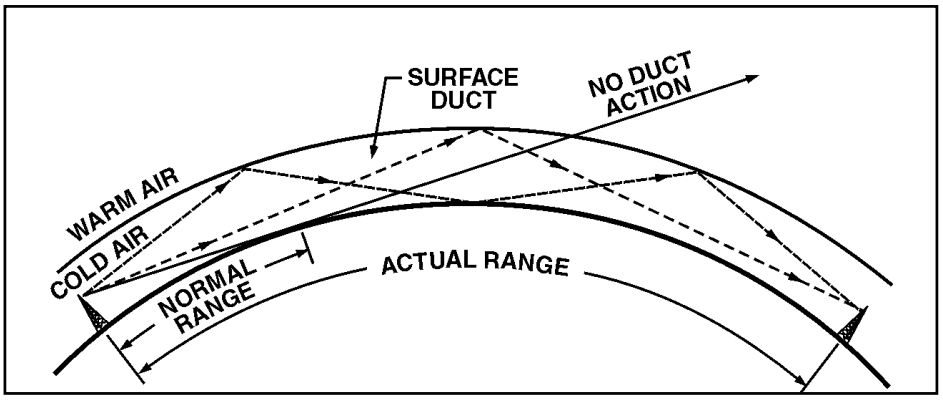

Figure 2-25. Duct Effect Caused by Temperature Inversion

TROPOSPHERIC PROPAGATION

2-132. As the lowest region of the earth's atmosphere, the troposphere extends from the earth's surface to a height of slightly over 7 miles. Virtually all weather phenomena occur in this region. Generally, the troposphere is characterized by a steady decrease in both temperature and pressure as height is increased. However, the many changes in weather phenomena cause variations in humidity and an uneven heating of the earth's surface. As a result, the air in the troposphere is in constant motion. This motion causes small turbulences, or eddies, to be formed, as shown by the bouncing of aircraft entering turbulent areas of the atmosphere. These turbulences are most intense near the earth's surface and gradually diminish with height. They have a refractive quality that permits the refracting or scattering of radio waves with short wavelengths. This scattering provides enhanced communications at higher frequencies.

2-133. Recall that in the relationship between frequency and wavelength, wavelength decreases as frequency increases and vice versa. Radio waves of frequencies below 30 megahertz normally have wavelengths longer than the size of weather turbulences. These radio waves are, therefore, affected very little by the turbulences. On the other hand, as the frequency increases into the VHF range and above, the wavelengths decrease in size, to the point that they become subject to tropospheric scattering. The usable frequency range for tropospheric scattering is from about 100 megahertz to 10 gigahertz.

Tropospheric Scattering

2-134. When a radio wave passing through the troposphere meets turbulence, it makes an abrupt change in velocity. This causes a small amount of the energy to be scattered in a forward direction and returned to Earth at distances beyond the horizon. This phenomenon is repeated as the radio wave meets other turbulences in its path. The total received signal is an accumulation of the energy received from each of the turbulences.

2-135. This scattering mode of propagation enables VHF and UHF signals to be transmitted far beyond the normal line-of-sight. To understand how these signals are transmitted over greater distances, you must first consider the propagation characteristics of the space wave used in VHF and UHF line-of-sight communications. When the space wave is transmitted, it undergoes very little attenuation within the line-of-sight horizon. When it reaches the horizon, the wave is diffracted and follows the earth's curvature. Beyond the horizon, the rate of attenuation increases very rapidly and signals soon become very weak and unusable.

2-136. Tropospheric scattering, on the other hand, provides a usable signal at distances beyond the point where the diffracted space wave drops to an unusable level. This is because of the height at which scattering takes place. The turbulence that causes the scattering can be visualized as a relay station located above the horizon; it receives the transmitted energy and then reradiates it in a forward direction to some point beyond the line-of-sight distance. A high gain-receiving antenna aimed toward this scattered energy can then capture it.

2-137. The magnitude of the received signal depends on the number of turbulences causing scatter in the desired direction and the gain of the receiving antenna. The scatter area used for tropospheric scatter is known as the scatter volume. The angle at which the receiving antenna must be aimed to capture the scattered energy is called the scatter angle. The scatter volume and scatter angles are shown in figure 2-26.

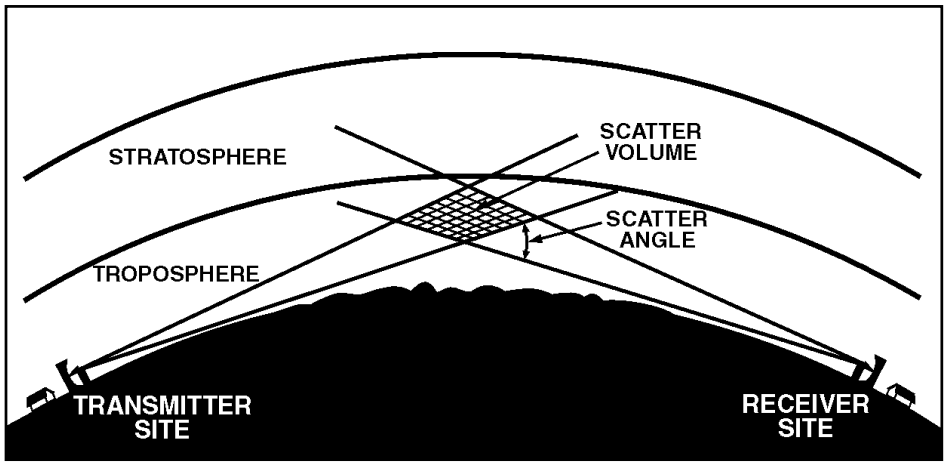

Figure 2-26. Tropospheric Scattering Propagation

2-138. The signal take-off angle (transmitting antenna's angle of radiation) determines the height of the scatter volume and the size of the scatter angle. A low signal take-off angle produces a low scatter volume, which in turn permits a receiving antenna that is aimed at a low angle to the scatter volume to capture the scattered energy.

2-139. As the signal take-off angle is increased, the height of the scatter volume is increased. When this occurs, the amount of received energy decreases. There are two reasons for this: (1) the scatter angle increases as the height of the scatter volume is increased; (2) the amount of turbulence

decreases with height. As the distance between the transmitting and receiving antennas is increased, the height of the scatter volume must also be increased. The received signal level, therefore, decreases as circuit distance is increased.

2-140. The tropospheric region that contributes most strongly to tropospheric scatter propagation lies near the midpoint between the transmitting and receiving antennas and just above the radio horizon of the antennas.

2-141. Because tropospheric scatter depends on turbulence in the atmosphere, changes in atmospheric conditions have an effect on the strength of the received signal. Both daily and seasonal variations in signal strength occur as a result of changes in the atmosphere. These variations are called long-term fading.

2-142. In addition to long-term fading, the tropospheric scatter signal often is characterized by very rapid fading because of multipath propagation. Because the turbulent condition is constantly changing, the path lengths and individual signal levels are also changing, resulting in a rapidly changing signal. Although the signal level of the received signal is constantly changing, the average signal level is stable; therefore, no complete fade-out occurs.

2-143. Another characteristic of a tropospheric scatter signal is its relatively low power level. Because very little of the scattered energy is reradiated toward the receiver, the efficiency is very low and the signal level at the final receiver point is low. Initial input power must be high to compensate for the low efficiency in the scatter volume. This is accomplished by using high-power transmitters and high-gain antennas, which concentrate the transmitted power into a beam, thus increasing the intensity of energy of each turbulence in the volume. The receiver must also be very sensitive to detect the low-level signals.

Application of Tropospheric Scattering

2-144. Tropospheric scatter propagation is used for point-to-point communications. A correctly designed tropospheric scatter circuit will provide highly reliable service for distances ranging from 50 miles to 500 miles. Tropospheric scatter systems may be particularly useful for communications to locations in rugged terrain that are difficult to reach with other methods of propagation. One reason for this is that the tropospheric scatter circuit is not affected by ionospheric and auroral disturbances.

SUMMARY

Now that you have completed this chapter, let us review some of the new terms, concepts, and ideas that you have learned. You should have a thorough understanding of these principles before moving on to chapter 3.

The induction field contains an E field and an H field and is localized near the antenna. The E and H fields of the induction field are 90 degrees out of phase with each other.

The radiation field contains E and H fields that are propagated from the antenna into space in the form of electromagnetic waves. The E and H fields of the radiation field are in phase with each other.

A harmonic frequency is any frequency that is a whole number multiple of a smaller basic frequency. For example, a radio wave transmitted at a fundamental frequency of 3000 hertz can have a second harmonic of 6000 hertz, a third harmonic frequency of 9000 hertz, and so on, transmitted at the same time.

A vertically polarized antenna transmits an electromagnetic wave with the E field perpendicular to the earth's surface. A horizontally polarized antenna transmits a radio wave with the E field parallel to the earth's surface.

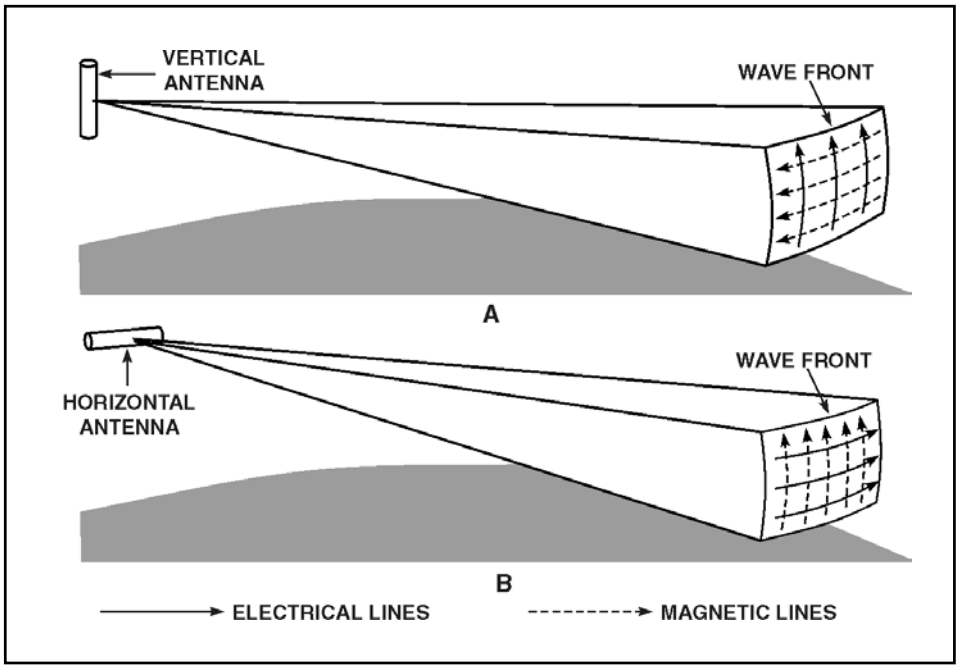

Figure 2-Sum 1. Vertical and Horizontal Polarization

A wavefront is a small section of an expanding sphere of radiated energy and is perpendicular to the direction of travel from the antenna.

Radio waves are electromagnetic waves that can be reflected, refracted, and diffracted in the atmosphere in the same manner as light and heat waves.

Reflected radio waves are waves that have been reflected from a surface and are 180 degrees out of phase with the initial wave.

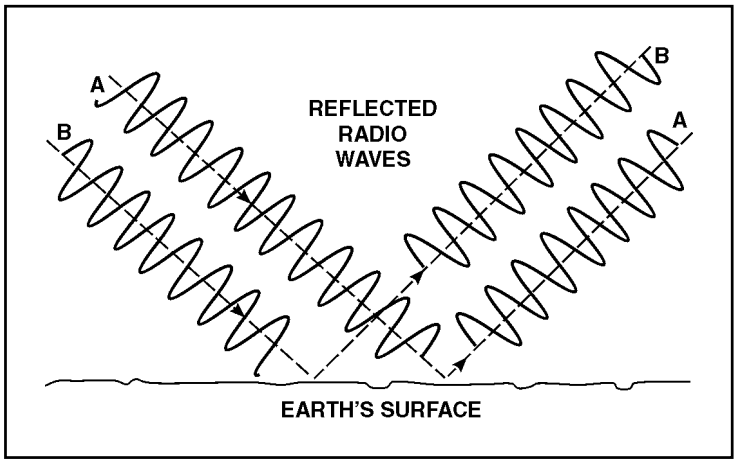

Figure 2-Sum 2. Phase Shift of Reflected Radio Waves

The earth's atmosphere is divided into three separate layers: the troposphere, the stratosphere, and the ionosphere.

The troposphere is the region of the atmosphere where virtually all weather phenomena take place. In this region, RF energy is greatly affected.

The stratosphere has a constant temperature and has little effect on radio waves.

The ionosphere contains four cloud-like layers of electrically charged ions, which aid in long distance communications.

Ground waves and sky waves are the two basic types of radio waves that transmit energy from the transmitting antenna to the receiving antenna.

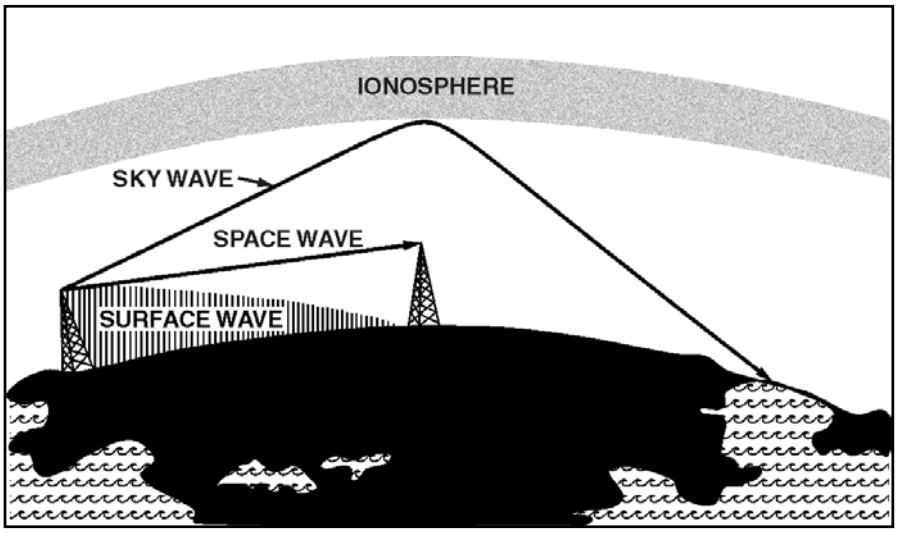

Figure 2-Sum 3. Ground and Sky Waves

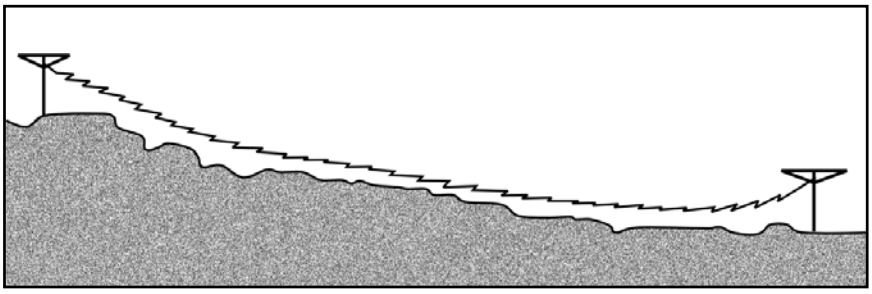

Figure 2-Sum 4. Surface Wave Propagation

Ground waves are composed of two separate component waves: the surface wave and the space wave.

Surface waves travel along the contour of the earth by diffraction.

Space waves can travel through the air directly to the receiving antenna or can be reflected from the surface of the earth.

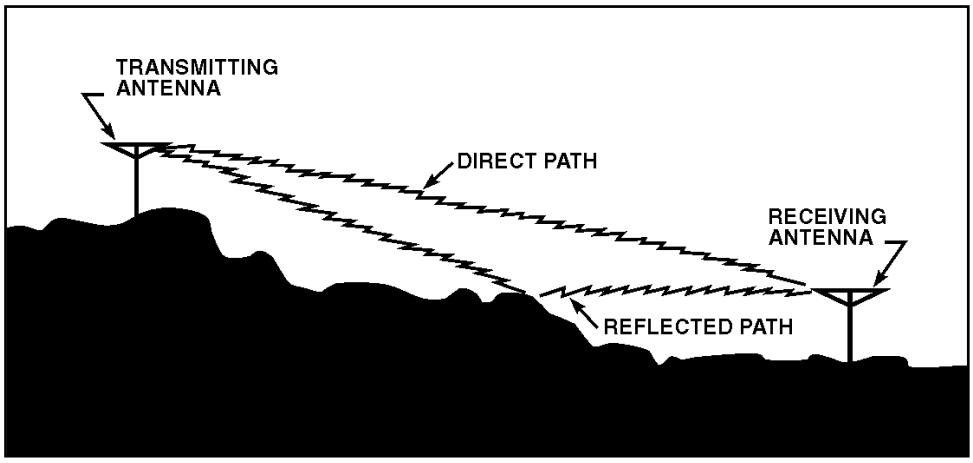

Figure 2-Sum 5. Space Wave Propagation

Sky waves, often called ionospheric waves, are radiated in an upward direction and returned to Earth at some distant location because of refraction.

Natural horizon is the line-of-sight horizon.

Radio horizon is one-third farther than the natural horizon.

The ionosphere consists of several layers of ions, formed by the process called ionization.

Ionization is the process of knocking electrons free from their parent atom, thus upsetting electrical neutrality.

Recombination is the opposite of ionization; that is, the free ions combine with positive ions, causing the positive ions to return to their original neutral atom state.

The D layer is the lowest region of the ionosphere and refracts signals of low frequencies back to Earth.

The E layer is present during the daylight hours, refracts signals as high as 20 megahertz back to Earth; and is used for communications up to 1500 miles.

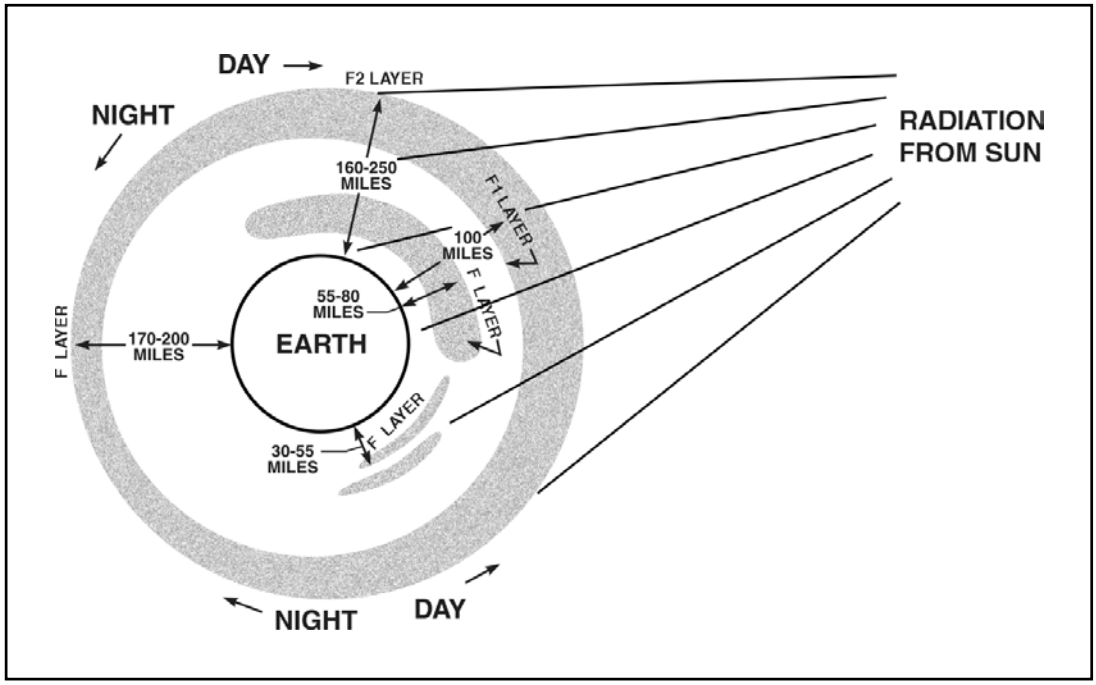

Figure 2-Sum 6. Layers of the Ionosphere

The F layer is divided into the F1 and F2 layers during the day but combine at night to form one layer. This layer is responsible for high frequency, long-range transmission.

The critical frequency is the maximum frequency that a radio wave can be transmitted vertically and still be refracted back to Earth.

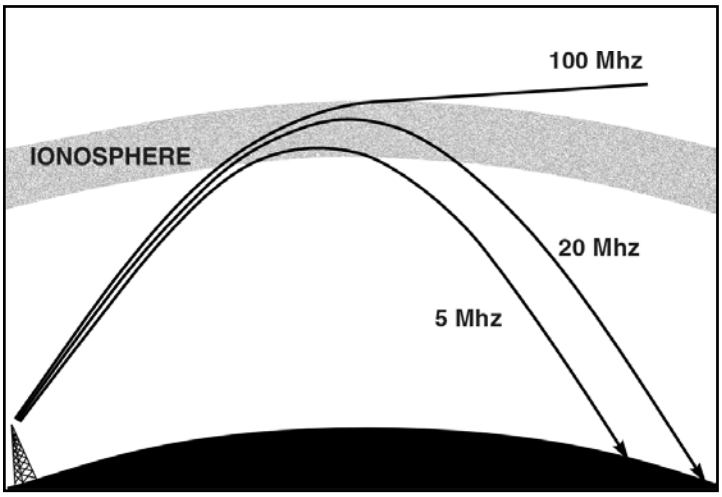

Figure 2-Sum 7. Frequency Versus Refraction and Distance

The critical angle is the maximum and/or minimum angle at which a radio wave can be transmitted and still be refracted back to Earth.

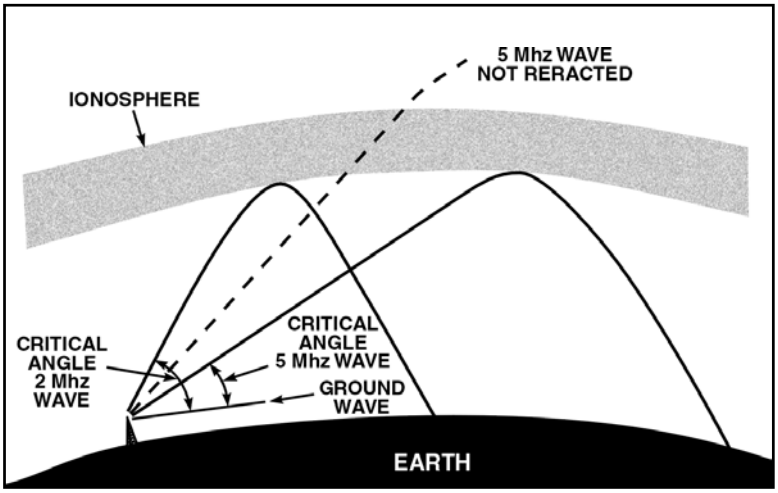

Figure 2-Sum 8. Effects of Frequency on Critical Angle

Skip distance is the distance between the transmitter and the point where the sky wave first returns to Earth.

Skip zone is the zone of silence between the point where the ground wave becomes too weak for reception and the point where the sky wave is first returned to Earth.

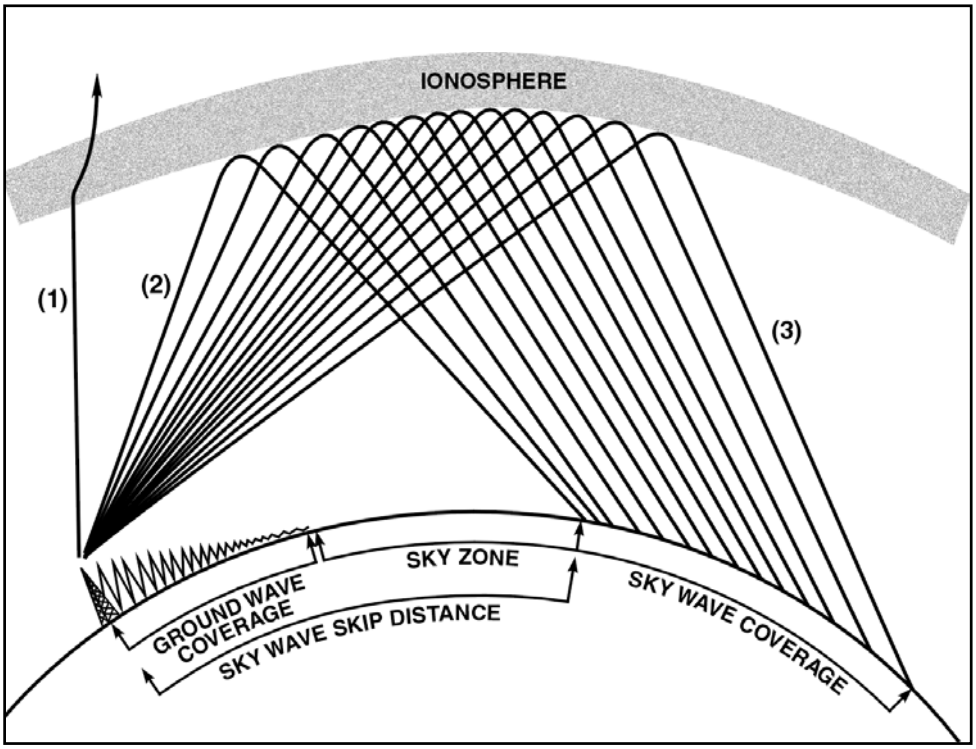

Figure 2-Sum 9. Relationship between Skip Zone, Skip Distance, and Ground Wave

Fading is caused by variations in signal strength, such as absorption of the RF energy by the ionosphere.

Multipath fading occurs when a transmitted signal divides and takes more than one path to a receiver and some of the signals arrive out of phase, resulting in a weak or fading signal.

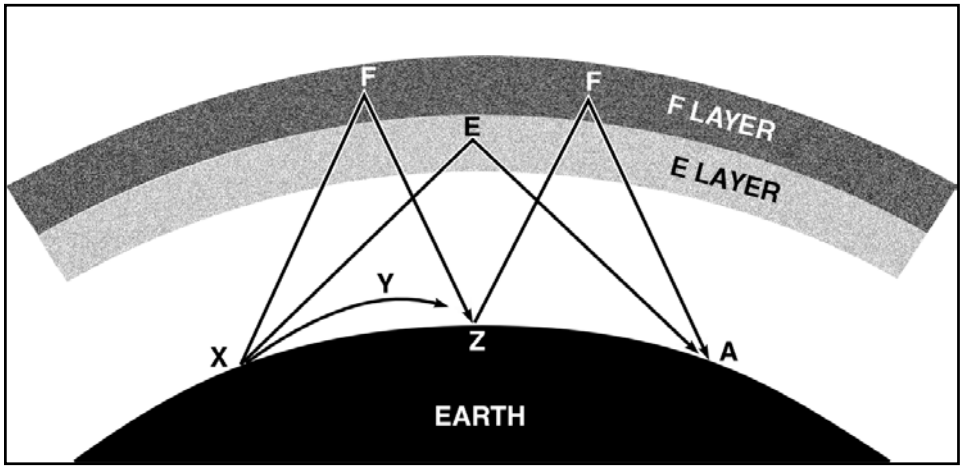

Figure 2-Sum 10. Multipath Transmission

Some transmission losses that affect radio-wave propagation are ionospheric absorption, ground reflection, and free-space losses.

Electromagnetic interference (EMI), both natural and man-made, interferes with radio communications.

The maximum usable frequency (MUF) is the highest frequency that can be used for communications between two locations at a given angle of incidence and time of day.

The lowest usable frequency (LUF) is the lowest frequency that can be used for communications between two locations.

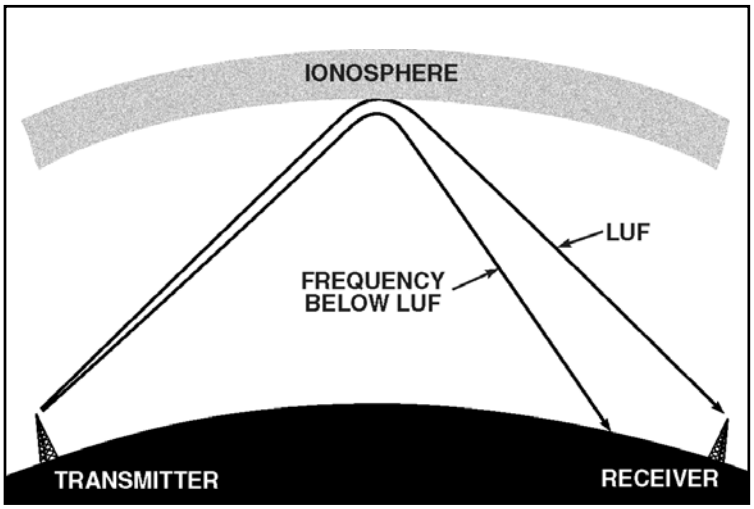

Figure 2-Sum 11. Refraction of Frequency below the Lowest Usable Frequency (LUF)

Optimum working frequency (FOT) is the most practical operating frequency and the one that can be relied on to have the fewest problems.

Precipitation attenuation can be caused by rain, fog, snow, and hail, and can affect overall communications considerably.

Temperature inversion causes channels, or ducts, of cool air to form between layers of warm air, which can cause radio waves to travel far beyond the normal line-of-sight distances.

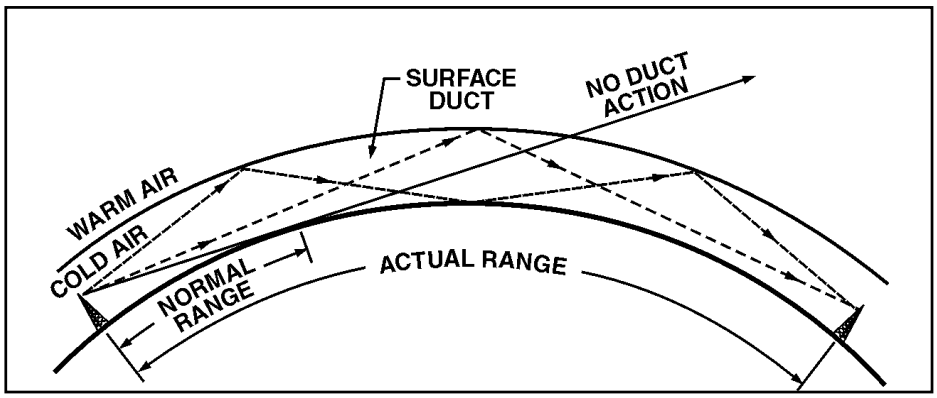

Figure 2-Sum 12. Duct Effect Caused by Temperature Inversion

Tropospheric propagation uses the scattering principle to achieve beyond the line-of-sight radio communications within the troposphere.

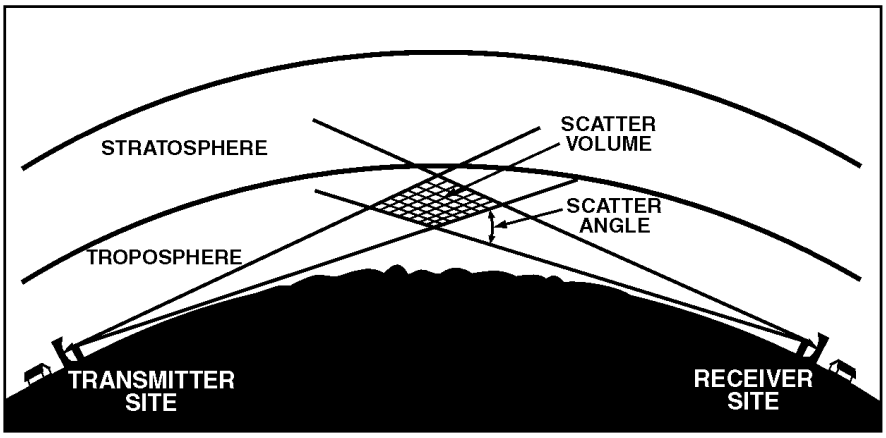

Figure 2-Sum 13. Tropospheric Scattering Propagation

Check-on-Learning Questions

Radio Wave Propagation

1. Which two composite fields (composed of E and H fields) are associated with every antenna?
2. What composite field (composed of E and H fields) is found stored in the antenna?
3. What composite field (composed of E and H fields) is propagated into free space?
4. What is the term used to describe the basic frequency of a radio wave?
5. What is the term used to describe a whole number multiple of the basic frequency of a radio wave?
6. It is known that WWV operates on a frequency of 10 megahertz. What is the wavelength of WWV?
7. A station is known to operate at 60 meters. What is the frequency of the unknown station?
8. If a transmitting antenna is placed close to the ground, how should the antenna be polarized to give the greatest signal strength?
9. In the right-hand rule for propagation, the thumb points in the direction of the E field and the forefinger points in the direction of the H field. In what direction does the middle finger point?
10. What is one of the major reasons for the fading of radio waves that have been reflected from a surface?
11. What are the three layers of the atmosphere?
12. Which layer of the atmosphere has relatively little effect on radio waves?
13. What is the determining factor in classifying whether a radio wave is a ground wave or a space wave?
14. What is the best type of surface or terrain to use for radio wave transmission?
15. What is the primary difference between the radio horizon and the natural horizon?
16. What three factors must be considered in the transmission of a surface wave to reduce attenuation?
17. What causes ionization to occur in the ionosphere?
18. How are the four distinct layers of the ionosphere designated?
19. What is the height of the individual layers of the ionosphere?
20. What factor determines whether a radio wave is reflected or refracted by the ionosphere?
21. There is a maximum frequency at which vertically transmitted radio waves can be refracted back to Earth. What is this maximum frequency called?
22. What three main factors determine the amount of refraction in the ionosphere?
23. What is the skip zone of a radio wave?
24. Where does the greatest amount of ionospheric absorption occur in the ionosphere?
25. What is meant by the term “multipath”?
26. When a wide band of frequencies is transmitted simultaneously, each frequency will vary in the amount of fading. What is this variable fading called?

27. What are the two main sources of electromagnetic interference (EMI) with which radio waves must compete?
28. Thunderstorms, snowstorms, cosmic sources, and the sun are a few examples of EMI sources. What type of EMI comes from these sources?
29. Motors, switches, voltage regulators, and generators are a few examples of EMI sources. What type of EMI comes from these sources?
30. What are three ways of controlling the amount of transmitter-generated EMI?
31. What are three ways of controlling radiated EMI during transmission?
32. What are the two general types of variations in the ionosphere?
33. What is the main difference between these two types of variations?
34. What are the four main classes of regular variation that affect the extent of ionization in the ionosphere?
35. What are the three more common types of irregular variations in the ionosphere?
36. What do the letters MUF, LUF, and FOT stand for?
37. When is MUF at its highest and why?
38. What happens to the radio wave if the LUF is too low?
39. What are some disadvantages of operating transmitters at or near the LUF?
40. What are some disadvantages of operating a transmitter at or near the MUF?
41. What is FOT?
42. How do raindrops affect radio waves?
43. How does fog affect radio waves at frequencies above 2 gigahertz?
44. How is the term “temperature inversion” used when referring to radio waves?
45. How does temperature inversion affect radio transmission?
46. In what layer of the atmosphere does virtually all weather phenomena occur?
47. Which radio frequency bands use the tropospheric scattering principle for propagation of radio waves?
48. Where is the tropospheric region that contributes most strongly to tropospheric scatter propagation?

Chapter 3

Principles of Transmission Lines

LEARNING OBJECTIVES

3-1. Upon completing this chapter, you should be able to do the following:

- State what a transmission line is and how transmission lines are used.
- Explain the operating principles of transmission lines.
- Describe the five types of transmission lines.
- State the length of a transmission line.
- Explain the theory of the transmission line.
- Define the term "lumped constants" in relation to a transmission line.
- Define the term "distributed constants" in relation to a transmission line.
- Define leakage current.
- Describe how the electromagnetic lines of force around a transmission line are affected by the distributed constants.
- Define the term "characteristic impedance" and explain how it affects the transfer of energy along a transmission line.
- State how the energy transfer along a transmission line is affected by characteristic impedance and the infinite line.
- Identify the cause of and describe the characteristics of reflections on a transmission line.
- Define the term "standing waves" as applied to a transmission line.
- Describe how standing waves are produced on a transmission line and identify the types of terminations.
- Describe the types of standing-wave ratios.

INTRODUCTION TO TRANSMISSION LINES

3-2. A transmission line is a device designed to guide electrical energy from one point to another. It is used, for example, to transfer the output RF energy of a transmitter to an antenna. This energy will not travel through normal electrical wire without great losses. Although the antenna can be connected directly to the transmitter, the antenna is usually located some distance away from the transmitter. A transmission line is used to connect the transmitter and the antenna.

3-3. The transmission line has a single purpose for both the transmitter and the antenna. This purpose is to transfer the energy output of the transmitter to the antenna with the least possible power loss. How well this is done depends on the special physical and electrical characteristics (impedance and resistance) of the transmission line.

TERMINOLOGY

3-4. All transmission lines have two ends (see figure 3-1). The end of a two-wire transmission line connected to a source is ordinarily called the input end or the generator end. Other names given to this end are transmitter end, sending end, and source. The other end of the line is called the output end or receiving end. Other names given to the output end are load end and sink.

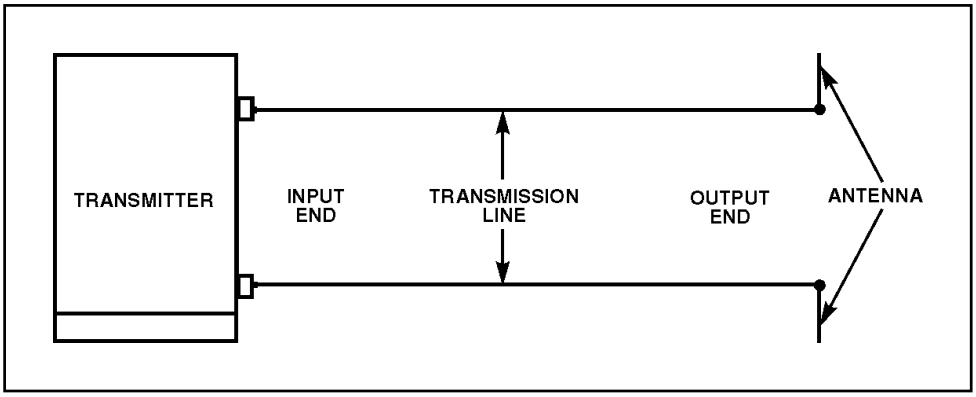

Figure 3-1. Basic Transmission Line

3-5. You can describe a transmission line in terms of its impedance. The ratio of voltage to current (E_{in}/I_{in}) at the input end is known as the input impedance (Z_{in}). This is the impedance presented to the transmitter by the transmission line and its load, the antenna. The ratio of voltage to current at the output (E_{out}/I_{out}) end is known as the output impedance (Z_{out}). This is the impedance presented to the load by the transmission line and its source. If an infinitely long transmission line could be used, the ratio of voltage to current at any point on that transmission line would be some particular value of impedance. This impedance is known as the characteristic impedance.

TYPES OF TRANSMISSION MEDIUMS

3-6. The Army uses many different types of transmission mediums in its electronic applications. Each medium (line or waveguide) has a certain characteristic impedance value, current-carrying capacity, and physical shape and is designed to meet a particular requirement.

3-7. The five types of transmission mediums discussed in this chapter include parallel line, twisted pair, shielded pair, coaxial line, and waveguides. The use of a particular line depends, among other things, on the applied frequency, the power-handling capabilities, and the type of installation.

Note. In the following paragraphs, we mention losses several times. Losses are discussed more thoroughly later in this chapter.

Parallel Line

3-8. One type of parallel line is the two-wire open line illustrated in figure 3-2. This line consists of two wires that are generally spaced from 2 to 6 inches apart by insulating spacers. This type of line is most often used for power lines, rural telephone lines, and telegraph lines. It is sometimes used

as a transmission line between a transmitter and an antenna or between an antenna and a receiver. An advantage of this type of line is its simple construction. The principal disadvantages of this type of line are the high radiation losses and electrical noise pickup because of the lack of shielding. The changing fields created by the changing current in each conductor produce radiation losses.

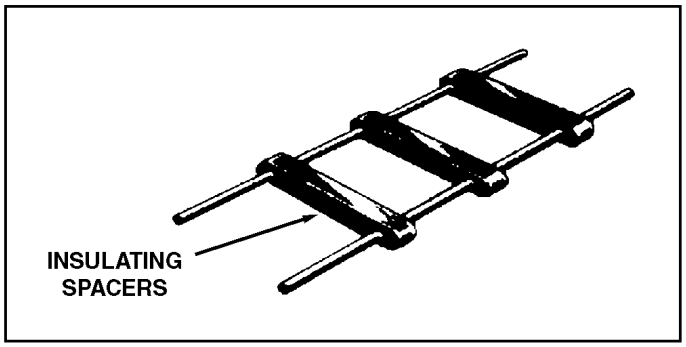

Figure 3-2. Parallel Two-Wire Open Line

3-9. Another type of parallel line is the two-wire ribbon (twin lead) illustrated in figure 3-3. This type of transmission line is commonly used to connect a television-receiving antenna to a home television set. This line is essentially the same as the two-wire open line except that uniform spacing is assured by embedding the two wires in a low-loss dielectric, usually polyethylene. Because the wires are embedded in the thin ribbon of polyethylene, the dielectric space is partly air and partly polyethylene.

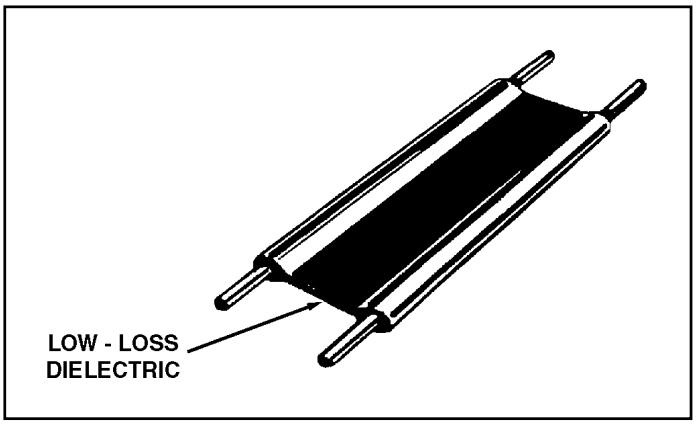

Figure 3-3. Two-Wire Ribbon Line

Twisted Pair

3-10. The twisted pair transmission line is illustrated in figure 3-4. As the name implies, the line consists of two insulated wires twisted together to form a flexible line without the use of spacers. It is not used for transmitting at high frequency because of the high dielectric losses that occur in the rubber insulation. When the line is wet, the losses increase greatly.

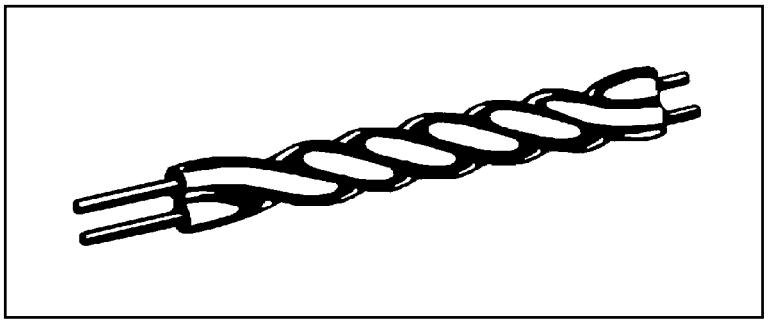

Figure 3-4. Twisted Pair

Shielded Pair

3-11. The shielded pair, shown in figure 3-5 consists of parallel conductors separated from each other and surrounded by a solid dielectric. The conductors are contained within braided copper tubing that acts as an electrical shield. The assembly is covered with a rubber or flexible composition coating that protects the line from moisture and mechanical damage. Outwardly, it looks much like the power cord of a washing machine or refrigerator.

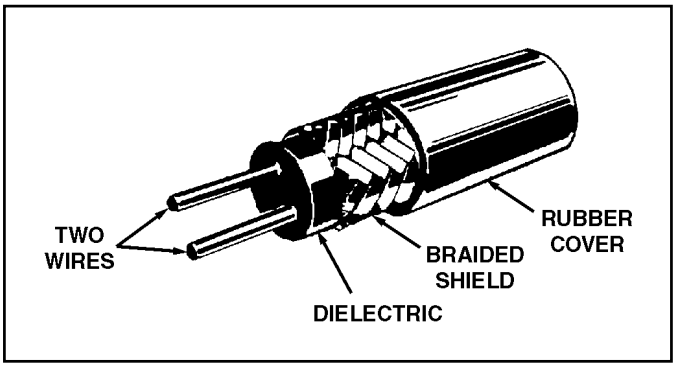

Figure 3-5. Shielded Pair

3-12. The principal advantage of the shielded pair is that the conductors are balanced to ground; that is, the capacitance between the wires is uniform throughout the length of the line. This balance is due to the uniform spacing of the grounded shield that surrounds the wires along their entire length. The braided copper shield isolates the conductors from stray magnetic fields.

Coaxial Lines

3-13. There are two types of coaxial lines: rigid (air) and flexible (solid) coaxial line. The physical construction of both types is basically the same; that is, each contains two concentric conductors.

3-14. The rigid coaxial line consists of a central, insulated wire (inner conductor) mounted inside a tubular outer conductor. This line is shown in figure 3-6. In some applications, the inner conductor is also tubular. Insulating spacers or beads at regular intervals insulates the inner conductor

from the outer conductor. The spacers are made of pyrex, polystyrene, or some other material that has good insulating characteristics and low dielectric losses at high frequencies.

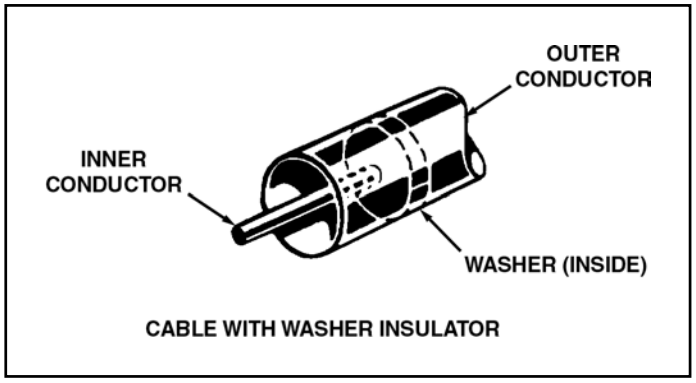

Figure 3-6. Rigid (Air) Coaxial Line

3-15. The chief advantage of the rigid line is its ability to minimize radiation losses. The electric and magnetic fields in a two-wire parallel line extend into space for relatively great distances and radiation losses occur. However, in a coaxial line no electric or magnetic fields extend outside of the outer conductor. The fields are confined to the space between the two conductors, resulting in a perfectly shielded coaxial line. Another advantage is that interference from other lines is reduced.

3-16. The rigid line has the following disadvantages: (1) it is expensive to construct; (2) it must be kept dry to prevent excessive leakage between the two conductors; and (3) although high-frequency losses are somewhat less than in previously mentioned lines, they are still excessive enough to limit the practical length of the line.

3-17. Leakage caused by the condensation of moisture is prevented in some rigid line applications by the use of an inert gas, such as nitrogen, helium, or argon. It is pumped into the dielectric space of the line at a pressure that can vary from 3 to 35 pounds per square inch. The inert gas is used to dry the line when it is first installed and pressure is maintained to ensure that no moisture enters the line.

3-18. Flexible coaxial lines (figure 3-7) are made with an inner conductor that consists of flexible wire insulated from the outer conductor by a solid, continuous insulating material. The outer conductor is made of metal braid, which gives the line flexibility. Early attempts at gaining flexibility involved using rubber insulators between the two conductors. However, the rubber insulators caused excessive losses at high frequencies.

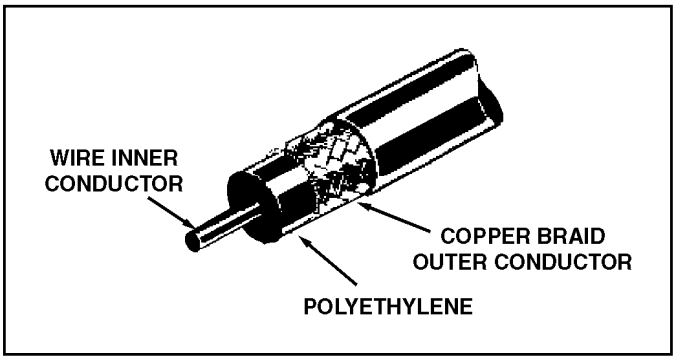

Figure 3-7. Flexible (Solid) Coaxial Line

3-19. Because of the high-frequency losses associated with rubber insulators, polyethylene plastic was developed to replace rubber and eliminate these losses. Polyethylene plastic is a solid substance that remains flexible over a wide range of temperatures. It is unaffected by seawater, gasoline, oil, and most other liquids that may be found aboard ship. The use of polyethylene as an insulator results in greater high-frequency losses than the use of air as an insulator. However, these losses are still lower than the losses associated with most other solid dielectric materials.

Waveguides

3-20. The waveguide is classified as a transmission line. However, the method by which it transmits energy down its length differs from the conventional methods. Waveguides are cylindrical, elliptical, or rectangular (cylindrical and rectangular shapes are shown in figure 3-8). The rectangular waveguide is used more frequently than the cylindrical waveguide.

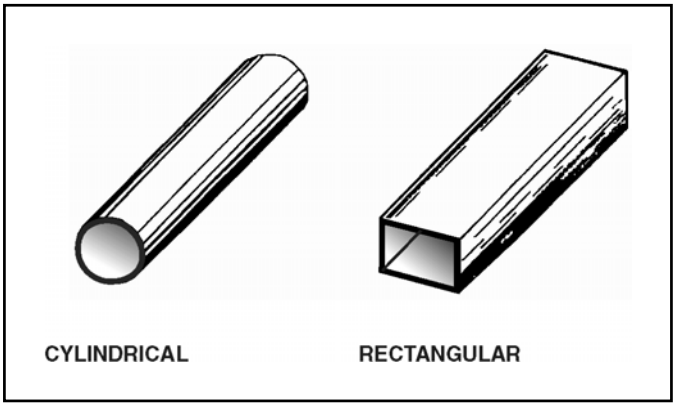

Figure 3-8. Waveguides

3-21. The term waveguide can be applied to all types of transmission lines in the sense that they are all used to guide energy from one point to another. However, usage has generally limited the term to mean a hollow metal tube or a dielectric transmission line. In this chapter, we use the term waveguide only to mean "hollow metal tube." It is interesting to note that the transmission of electromagnetic energy along a waveguide travels at a velocity somewhat slower than electromagnetic energy traveling through free space.

3-22. A waveguide may be classified according to its cross section (rectangular, elliptical, or circular), or according to the material used in its construction (metallic or dielectric). Dielectric waveguides are seldom used because the dielectric losses for all known dielectric materials are too great to transfer the electric and magnetic fields efficiently.

3-23. The installation of a complete waveguide transmission system is somewhat more difficult than the installation of other types of transmission lines. The radius of bends in the waveguide must measure greater than two wavelengths at the operating frequency of the equipment to avoid excessive attenuation. The cross section must remain uniform around the bend. These requirements hamper installation in confined spaces. If the waveguide is dented, or if solder is permitted to run inside the joints, the attenuation of the line is greatly increased. Dents and obstructions in the waveguide also reduce its breakdown voltage, thus limiting the waveguide's power-handling capability because of possible arc-over. Great care must be exercised during installation; one or two carelessly made joints can seriously inhibit the advantage of using the waveguide.

LOSSES IN TRANSMISSION LINES

3-24. The discussion of transmission lines so far has not directly addressed line losses; actually some line losses occur in all lines. Line losses may be any of three types—copper, dielectric, and radiation or induction losses.

Note. Transmission lines are sometimes referred to as RF lines. In this text the terms are used interchangeably.

Copper Losses

3-25. One type of copper loss is I2R loss. In RF lines, the resistance of the conductors is never equal to zero. Whenever current flows through one of these conductors, some energy is dissipated in the form of heat. This heat loss is a power loss. With copper braid, which has a higher resistance than solid tubing, this power loss is higher.

3-26. Another type of copper loss is due to skin effect. When DC flows through a conductor, the movement of electrons through the conductor's cross section is uniform. The situation is somewhat different when AC is applied. The expanding and collapsing fields about each electron encircle other electrons. This phenomenon, called self-induction, retards the movement of the encircled electrons. The flux density at the center is so great that electron movement at this point is reduced. As frequency is increased, the opposition to the flow of current in the center of the wire increases. Current in the center of the wire becomes smaller and most of the electron flow is on the wire surface. When the frequency applied is 100 megahertz or higher, the electron movement in the center is so small that the center of the wire could be removed without any noticeable effect on current. You should be able to see that the effective cross-sectional area decreases as the frequency increases.

3-27. Because resistance is inversely proportional to the cross-sectional area, the resistance will increase as the frequency is increased. Also, because power loss increases as resistance increases, power losses increase with an increase in frequency because of skin effect. Skin effect is a tendency for

alternating current (AC) to flow mostly near the outer surface of a solid electrical conductor, such as metal wire, at frequencies above the audio range. The effect becomes more and more apparent as the frequency increases.

3-28. Copper losses can be minimized and conductivity increased in an RF line by plating the line with silver. Because silver is a better conductor than copper, most of the current will flow through the silver layer. The tubing then serves primarily as a mechanical support.

Dielectric Losses

3-29. Dielectric losses result from the heating effect on the dielectric material between the conductors. Power from the source is used in heating the dielectric. The heat produced is dissipated into the surrounding medium. When there is no potential difference between two conductors, the atoms in the dielectric material between them are normal and the orbits of the electrons are circular. When there is a potential difference between two conductors, the orbits of the electrons change. The excessive negative charge on one conductor repels electrons on the dielectric toward the positive conductor and thus distorts the orbits of the electrons. A change in the path of electrons requires more energy, introducing a power loss.

3-30. The atomic structure of rubber is more difficult to distort than the structure of some other dielectric materials. The atoms of materials, such as polyethylene, distort easily. Therefore, polyethylene is often used as a dielectric because less power is consumed when its electron orbits are distorted.

Radiation and Induction Losses

3-31. Radiation and induction losses are similar in that the fields surrounding the conductors cause both. Induction losses occur when the electromagnetic field about a conductor cuts through any nearby metallic object and a current is induced in that object. As a result, power is dissipated in the object and is lost.

3-32. Radiation losses occur because some magnetic lines of force about a conductor do not return to the conductor when the cycle alternates. These lines of force are projected into space as radiation and this results in power losses. That is, power is supplied by the source, but is not available to the load.

LENGTH OF A TRANSMISSION LINE

3-33. A transmission line is considered to be electrically short when its physical length is short compared to a quarter-wavelength (¼λ) of the energy it is to carry.

Note. In this document, for ease of reading, the value of the wavelength is spelled out in some cases, and in other cases, the numerical value is used.

3-34. A transmission line is electrically long when its physical length is long compared to a quarter-wavelength of the energy it is to carry. You must understand that the terms “short” and “long” are relative ones. For example, a line that has a physical length of 3 meters (approximately 10 feet) is considered quite short electrically if it transmits a radio frequency of

30 kilohertz. On the other hand, the same transmission line is considered electrically long if it transmits a frequency of 30,000 megahertz.

3-35. To show the difference in physical and electrical lengths of the lines mentioned above, compute the wavelength of the two frequencies, taking the 30-kilohertz example first—

Given:

$$\lambda = \frac{v}{f}$$

Where:

λ = wavelength

v = velocity of RF in free space

f = frequency of transmission

Hz = cycles per second

Solution:

$$\lambda = \frac{300 \times 10^6 \text{ meters/second}}{30 \times 10^3 \text{ cycles/second (Hz)}}$$

$$\lambda = 10 \times 10^3 \text{ meters/cycle}$$

λ = 10,000 meters, or approximately 6 miles for a complete wavelength

3-36. Now, computing the wavelength for the line carrying 30,000 megahertz—

$$\lambda = \frac{v}{f}$$

$$\lambda = \frac{300 \times 10^6 \text{ meters/second}}{30{,}000 \times 10^6 \text{ cycles/second (Hz)}}$$

$$\lambda = \frac{1}{100} \text{ meter/cycle}$$

λ = .01 meter or approximately .03 foot for a complete wavelength

3-37. Thus, you can see that a 3-meter line is electrically very short for a frequency of 30 kilohertz. Also, the 3-meter line is electrically very long for a frequency of 30,000 megahertz.

3-38. When power is applied to a very short transmission line, practically all of it reaches the load at the output end of the line. This very short transmission line is usually considered to have practically no electrical properties of its own, except for a small amount of resistance.

3-39. However, the picture changes considerably when a long line is used. Because most transmission lines are electrically long (because of the distance from transmitter to antenna), the properties of such lines must be considered. Frequently, the voltage necessary to drive a current through a long line is

considerably greater than the amount that can be accounted for by the impedance of the load in series with the resistance of the line.

TRANSMISSION LINE THEORY

3-40. The electrical characteristics of a two-wire transmission line depend primarily on the construction of the line. The two-wire line acts like a long capacitor. The change of its capacitive reactance is noticeable as the frequency applied to it is changed. Because the long conductors have a magnetic field about them when electrical energy is being passed through them, they also exhibit the properties of inductance. The values of inductance and capacitance presented depend on the various physical factors that we discussed earlier in this chapter. For example, the type of line used, the dielectric in the line, and the length of the line must be considered. The effects of the inductive and capacitive reactances of the line depend on the frequency applied. Because no dielectric is perfect, electrons manage to move from one conductor to the other through the dielectric. Each type of two-wire transmission line also has a conductance value. This conductance value represents the value of the current flow that may be expected through the insulation. If the line is uniform (all values equal at each unit length), then one small section of the line may represent several feet. This illustration of a two-wire transmission line is used throughout the following discussion of transmission lines; but keep in mind that the principles presented here apply to all transmission lines. We explain the theories using lumped constants and distributed constants to simplify these principles further.

LUMPED CONSTANTS

3-41. A transmission line has the properties of inductance, capacitance, and resistance, just as the more conventional circuits have. Usually, however, the constants in conventional circuits are lumped into a single device or component. For example, a coil of wire has the property of inductance. When a certain amount of inductance is needed in a circuit, a coil of the proper dimensions is inserted. The inductance of the circuit is lumped into the one component. Two metal plates separated by a small space can be used to supply the required capacitance for a circuit. In such a case, most of the capacitance of the circuit is lumped into this one component. Similarly, a fixed resistor can be used to supply a certain value of circuit resistance as a lumped sum. Ideally, a transmission line would also have its constants of inductance, capacitance, and resistance lumped together, as shown in figure 3-9. Transmission line constants are distributed, as described below.

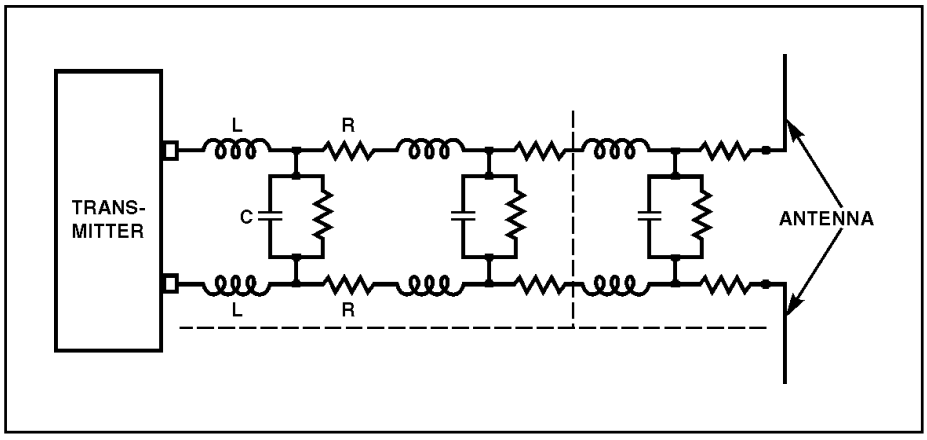

Figure 3-9. Equivalent Circuit of a Two-Wire Transmission Line

DISTRIBUTED CONSTANTS

3-42. Transmission line constants, called distributed constants, are spread along the entire length of the transmission line and cannot be distinguished separately. The amount of inductance, capacitance, and resistance depends on the length of the line, the size of the conducting wires, the spacing between the wires, and the dielectric (air or insulating medium) between the wires.

Inductance of a Transmission Line

3-43. When current flows through a wire, magnetic lines of force are set up around the wire. As the current increases and decreases in amplitude, the field around the wire expands and collapses accordingly. The energy produced by the magnetic lines of force collapsing back into the wire tends to keep the current flowing in the same direction. This represents a certain amount of inductance, which is expressed in microhenrys per unit length. Figure 3-10 illustrates the inductance and magnetic fields of a transmission line.

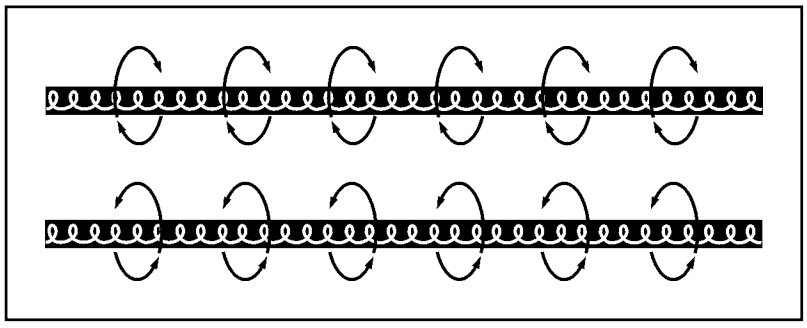

Figure 3-10. Distributed Inductance

Capacitance of a Transmission Line

3-44. Capacitance also exists between the transmission line wires, as illustrated in figure 3-11. Notice that the two parallel wires act as plates of a capacitor and that the air between them acts as a dielectric. The capacitance between the wires is usually expressed in picofarads per unit length. This electric field between the wires is similar to the field that exists between the two plates of a capacitor.

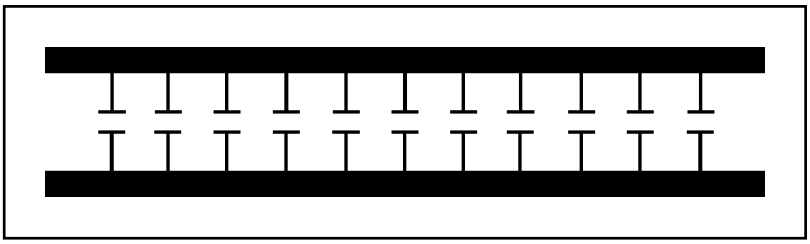

Figure 3-11. Distributed Capacitance

Resistance of a Transmission Line

3-45. The transmission line shown in figure 3-12 has electrical resistance along its length. This resistance is usually expressed in ohms per unit length and is shown as existing continuously from one end of the line to the other.

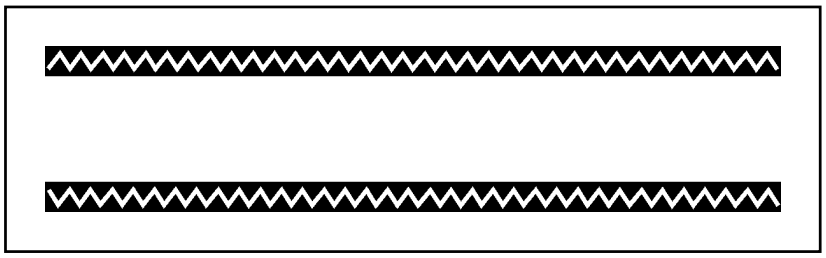

Figure 3-12. Distributed Resistance

Leakage Current

3-46. Because any dielectric, even air, is not a perfect insulator, a small current known as leakage current flows between the two wires. In effect, the insulator acts as a resistor, permitting current to pass between the two wires. Figure 3-13 shows this leakage path as resistors in parallel connected between the two lines. This property is called conductance (G) and is the opposite of resistance. Conductance in transmission lines is expressed as the reciprocal of resistance and is usually given in micromhos per unit length.

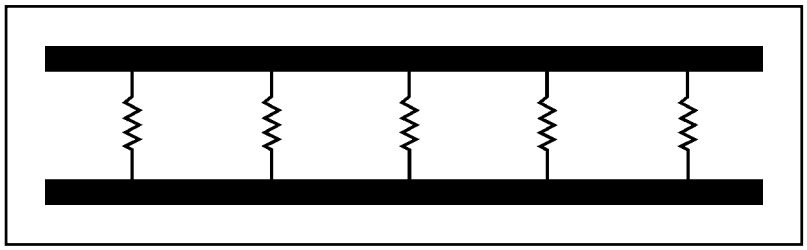

Figure 3-13. Leakage in a Transmission Line

ELECTROMAGNETIC FIELDS ABOUT A TRANSMISSION LINE

3-47. The distributed constants of resistance, inductance, and capacitance are basic properties common to all transmission lines and exist whether or not any current flow exists. As soon as current flow and voltage exist in a transmission line, another property becomes quite evident. This is the presence of an electromagnetic field, or lines of force, about the wires of the transmission line. The lines of force themselves are not visible; however, understanding the force that an electron experiences while in the field of these lines is very important to your understanding of energy transmission.

3-48. There are two kinds of fields; one is associated with voltage and the other with current. The field associated with voltage is called the electric (E) field. It exerts a force on any electric charge placed in it. The field associated with current is called a magnetic (H) field, because it tends to exert a force on any magnetic pole placed in it. Figure 3-14 illustrates the way in which the E fields and H fields tend to orient themselves between conductors of a typical two-wire transmission line. The illustration shows a cross section of the transmission lines. The E field is represented by solid lines and the H field by dotted lines. The arrows indicate the direction of the lines of force. Both fields normally exist together and are spoken of collectively as the electromagnetic field.

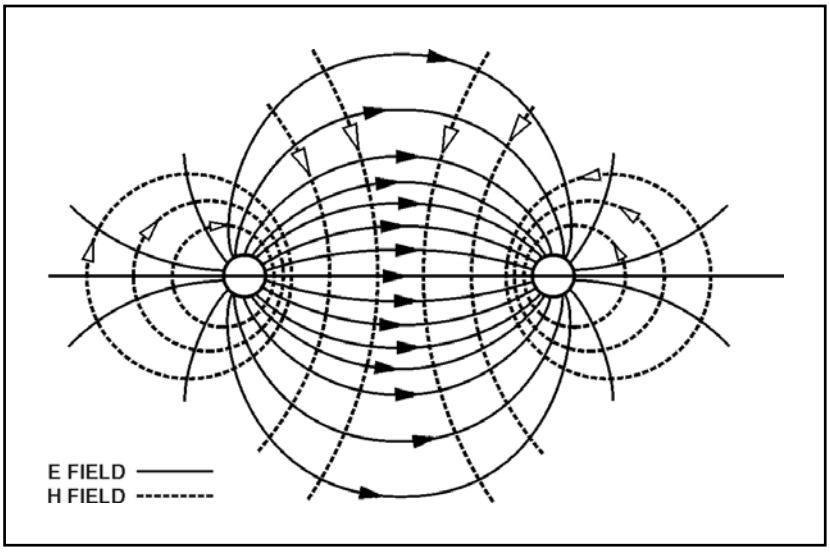

Figure 3-14. Fields between Conductors

CHARACTERISTIC IMPEDANCE OF A TRANSMISSION LINE

3-49. You learned earlier that the maximum (and most efficient) transfer of electrical energy takes place when the source impedance is matched to the load impedance. This fact is very important in the study of transmission lines and antennas. If the characteristic impedance of the transmission line and the load impedance are equal, energy from the transmitter will travel down the transmission line to the antenna with no power loss caused by reflection.

Definition and Symbols

3-50. Every transmission line possesses certain characteristic impedance, usually designated as Z_0. Z_0 is the ratio of E to I at every point along the line. If a load equal to the characteristic impedance is placed at the output end of any length of line, the same impedance will appear at the input terminals of the line. The characteristic impedance is the only value of impedance for any given type and size of line that acts in this way. The characteristic impedance determines the amount of current that can flow when a given voltage is applied to an infinitely long line. Characteristic impedance is comparable to the resistance that determines the amount of current that flows in a DC circuit.

3-51. Lumped and distributed constants were explained earlier in this chapter. Figure 3-15, view A, shows the properties of resistance (R), inductance (L), capacitance (C), and conductance (G) combined in a short section of two-wire transmission line. The illustration shows the evenly distributed capacitance as a single lumped capacitor and the distributed conductance as a lumped leakage path. Lumped values may be used for transmission line calculations if the physical length of the line is very short compared to the wavelength of energy being transmitted. Figure 3-15, view B, shows all four properties lumped together and represented by their conventional symbols.

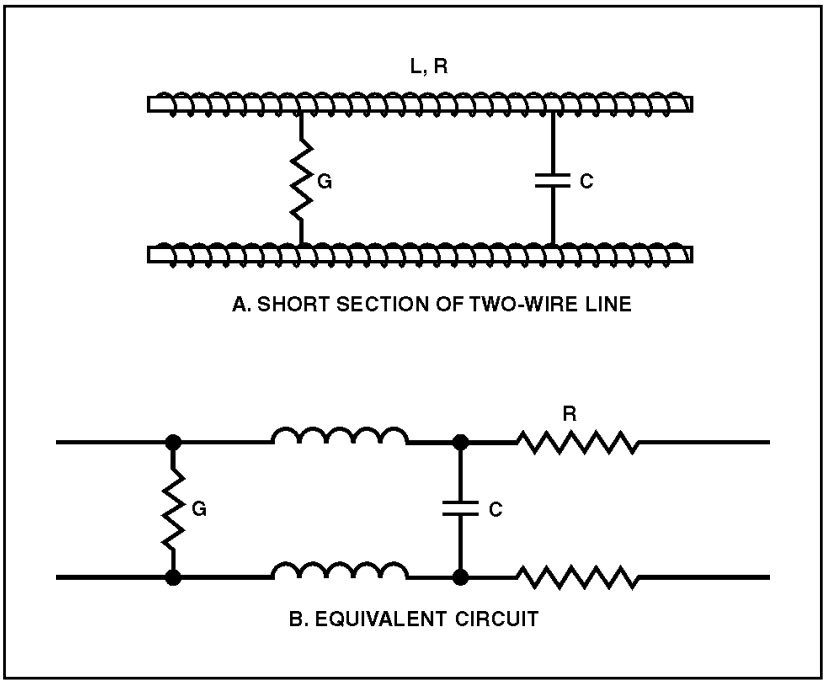

Figure 3-15. Short Section of Two-Wire Transmission Line and Equivalent Circuit

Characteristic Impedance and the Infinite Line

3-52. Like those shown in figure 3-15, several short sections can be combined to form a large transmission line, as shown in figure 3-16. Current will flow if voltage is applied across points K and L. In fact, any circuit, such as that represented in figure 3-16, view A, has a certain current flow for each value of applied voltage. The ratio of the voltage to the current is the impedance (Z), as expressed in the following formula:

$$Z = \frac{E}{I}$$

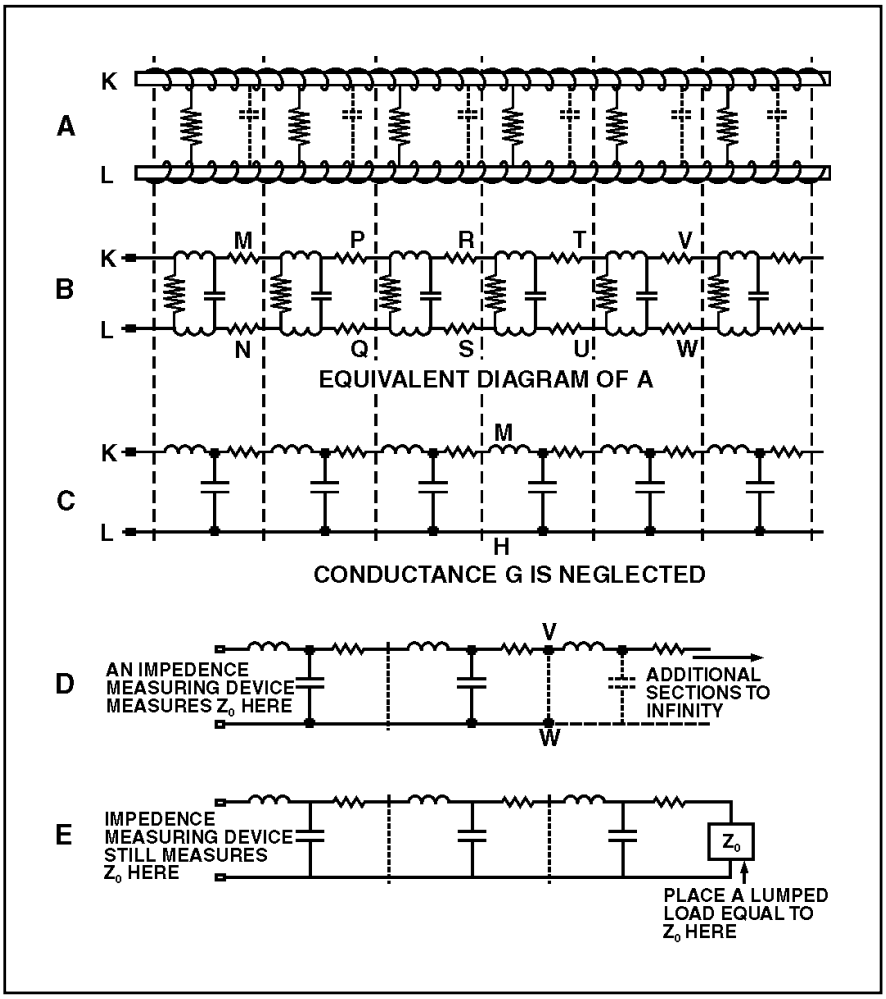

Figure 3-16. Characteristic Impedance

3-53. The impedance presented to the input terminals of the transmission line is not merely the resistance of the wire in series with the impedance of the load. The effects of series inductance and shunt capacitance of the line itself may overshadow the resistance, and even the load, as far as the input terminals are concerned.

3-54. To find the input impedance of a transmission line, determine the impedance of a single section of line. The impedance between points K and L, in figure 3-16, view B, can be calculated by the use of series-parallel impedance formulas, provided the impedance across points M and N is known. But because this section is merely one small part of a longer line, another similar section is connected to points M and N. Again, the impedance across points K and L of the two sections can be calculated, provided the impedance of the third section is known. This process of adding one section to another can be repeated endlessly. The addition of each section produces an impedance across points K and L of a new and lower value. However, after many sections have been added, each successive added section has less and less effect on the impedance across points K and L. If sections are added to

the line endlessly, the line is infinitely long, and a certain finite value of impedance across points K and L is finally reached.

3-55. In this discussion of transmission lines, the effect of conductance (G) is minor compared to that of inductance (L) and capacitance (C), and is frequently neglected. In figure 3-16, view C, G is omitted and the inductance and resistance of each line can be considered as one line.

3-56. Let us assume that the sections of figure 3-16, view C continue to the right with an infinite number of sections. When an infinite number of sections extends to the right, the impedance appearing across K and L is Z_0. If the line is cut at R and S, an infinite number of sections still extends to the right because the line is endless in that direction. Therefore, the impedance now appearing across points R and S is also Z_0, as illustrated in view D. You can see that if only the first three sections are taken and a load impedance of Z_0 is connected across points R and S, the impedance across the input terminals K and L is still Z_0. The line continues to act as an infinite line, as illustrated in view E.

3-57. Figure 3-17, view A illustrates how the characteristic impedance of an infinite line can be calculated. Resistors are added in series parallel across terminals K and L in eight steps, and the resultant impedances are noted. In step 1 the impedance is infinite; in step 2 the impedance is 110 ohms. In step 3 the impedance becomes 62.1 ohms, a change of 47.9 ohms. In step 4 the impedance is 48.5 ohms, a change of only 13.6 ohms. The resultant changes in impedance from each additional increment become progressively smaller. Eventually, practically no change in impedance results from further additions to the line. The total impedance of the line at this point is said to be at its characteristic impedance; which, in this case, is 37 ohms. This means that an infinite line constructed as indicated in step 8 could be effectively replaced by a 37-ohm resistor. View B shows a 37-ohm resistor placed in the line at various points to replace the infinite line of step 8 in view A. There is no change in total impedance.

3-58. In figure 3-17, resistors were used to show impedance characteristics for the sake of simplicity. Figuring the actual impedance of a line having reactance is very similar, with inductance taking the place of the series resistors and capacitance taking the place of the shunt resistors. The characteristic impedance of lines in actual use normally lies between 50 and 600 ohms.

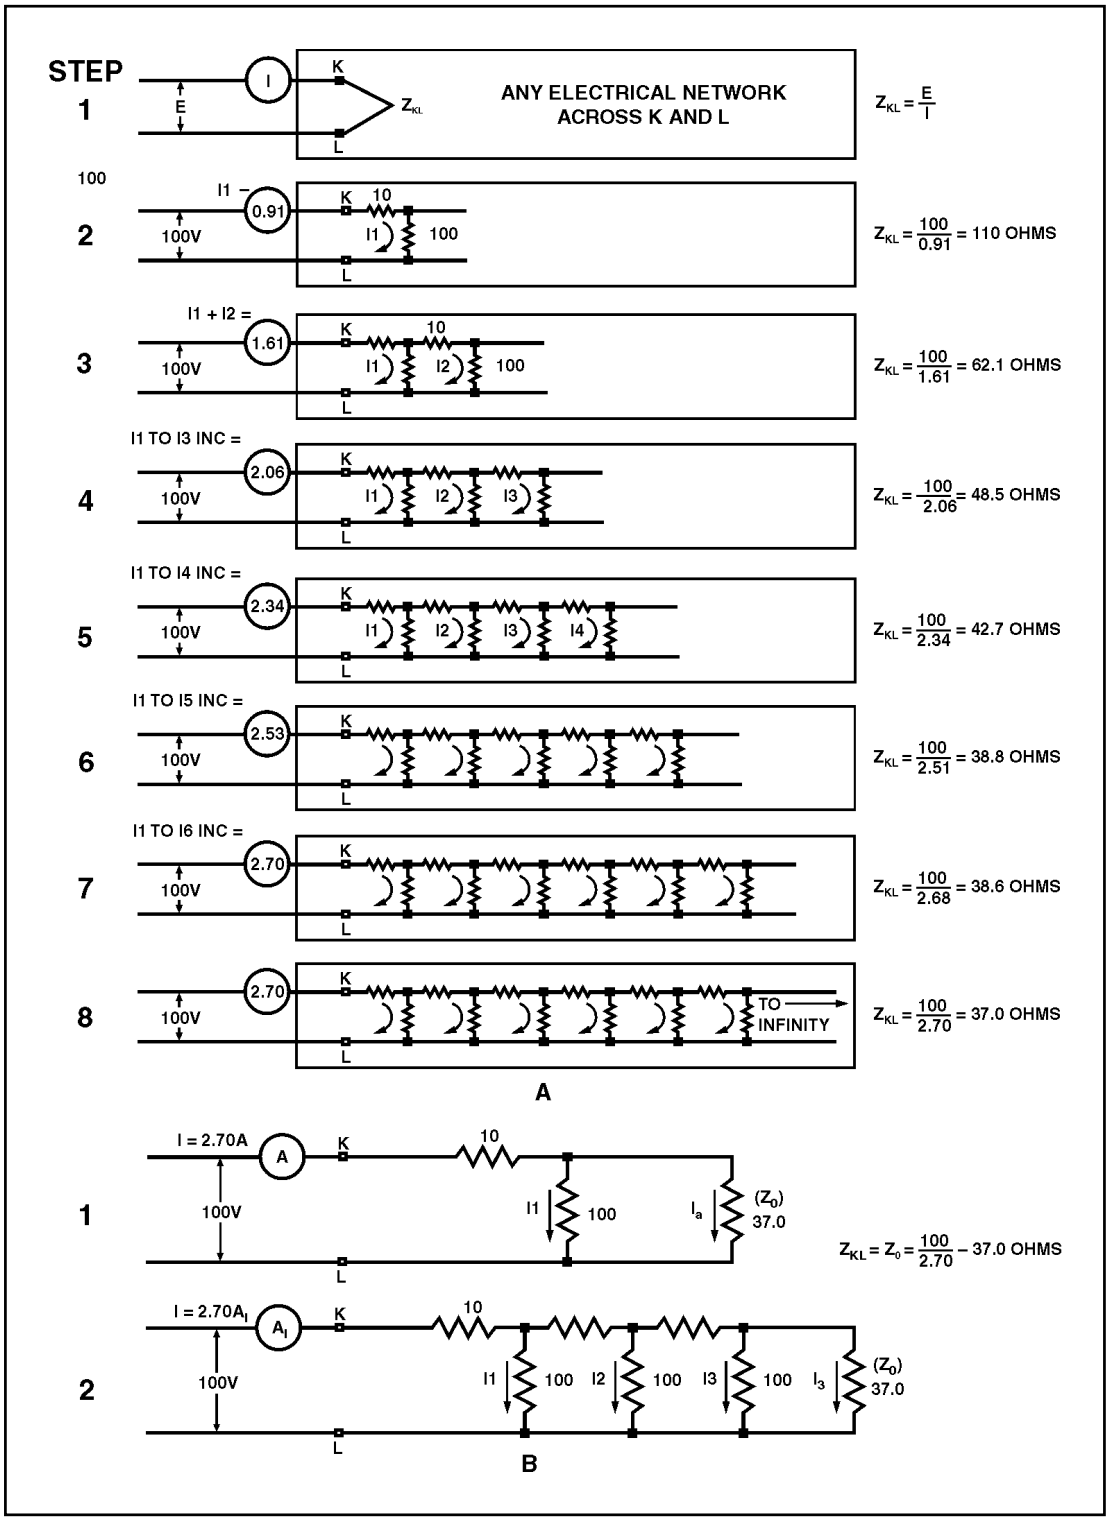

Figure 3-17 Termination of a Line

3-59. When a transmission line is "short" compared to the length of the RF waves it carries, the opposition presented to the input terminals is determined primarily by the load impedance. A small amount of power is dissipated in overcoming the resistance of the line. However, when the line is "long" and the load is an incorrect impedance, the voltages necessary to drive a given amount of current through the line cannot be accounted for by considering just the impedance of the load in series with the impedance of the line. The line has properties other than resistance that affect input impedance. These properties are inductance in series with the line, capacitance across the line, resistance leakage paths across the line, and certain radiation losses.

VOLTAGE CHANGE ALONG A TRANSMISSION LINE

3-60. Let us summarize what we have just discussed. In an electric circuit, energy is stored in electric and magnetic fields. These fields must be brought to the load to transmit that energy. At the load, energy contained in the fields is converted to the desired form of energy.

Transmission of Energy

3-61. When the load is connected directly to the source of energy, or when the transmission line is short, problems concerning current and voltage can be solved by applying Ohm's law. When the transmission line becomes long enough so the time difference between a change occurring at the generator and the change appearing at the load becomes appreciable, analysis of the transmission line becomes important.

DC Applied to a Transmission Line

3-62. In figure 3-18, a battery is connected through a relatively long two-wire transmission line to a load at the far end of the line. At the instant the switch is closed, neither current nor voltage exists on the line. When the switch is closed, point A becomes a positive potential, and point B becomes negative. These points of difference in potential move down the line. However, as the initial points of potential leave points A and B, they are followed by new points of difference in potential which the battery adds at A and B. This is merely saying that the battery maintains a constant potential difference between points A and B. A short time after the switch is closed, the initial points of difference in potential have reached points A' and B'; the wire sections from points A to A' and points B to B' are at the same potential as A and B, respectively. The points of charge are represented by plus (+) and minus (-) signs along the wires. The directions of the currents in the wires are represented by the arrowheads on the line, and the direction of travel is indicated by an arrow below the line. Conventional lines of force represent the electric field that exists between the opposite kinds of charge on the wire sections from A to A' and B to B'. Crosses (tails of arrows) indicate the magnetic field created by the electric field moving down the line. The moving electric field and the accompanying magnetic field constitute an electromagnetic wave that is moving from the generator (battery) toward the load. This wave travels at approximately the speed of light in free space. The energy reaching the load is equal to that developed at the battery (assuming there are no losses in the transmission line). If the load absorbs all of the energy, the current and voltage will be evenly distributed along the line.

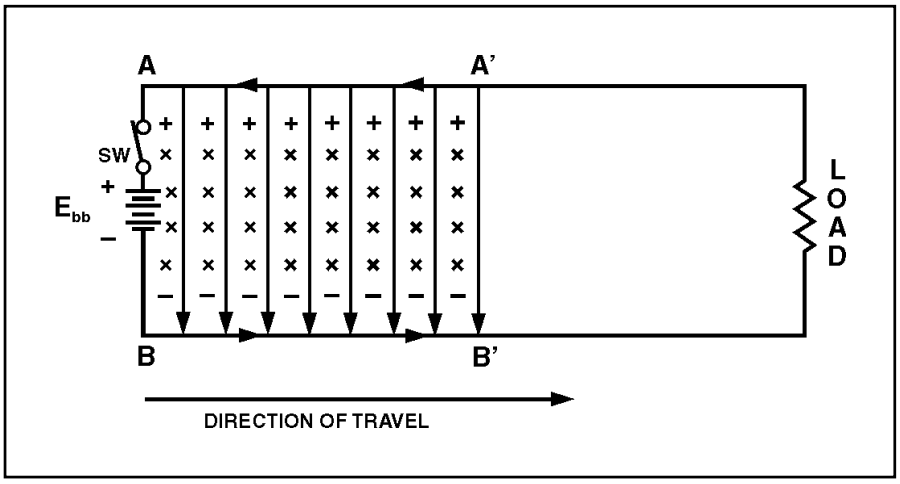

Figure 3-18. DC Voltage Applied to a Line

AC Applied to a Transmission Line

3-63. When the battery of figure 3-18 is replaced by an AC generator (figure 3-19), each successive instantaneous value of the generator voltage is propagated down the line at the speed of light. The action is similar to the wave created by the battery except that the applied voltage is sinusoidal instead of constant. Assume that the switch is closed at the moment the generator voltage is passing through zero and that the next half cycle makes point A positive. At the end of one cycle of generator voltage, the current and voltage distribution will be as shown in figure 3-19.

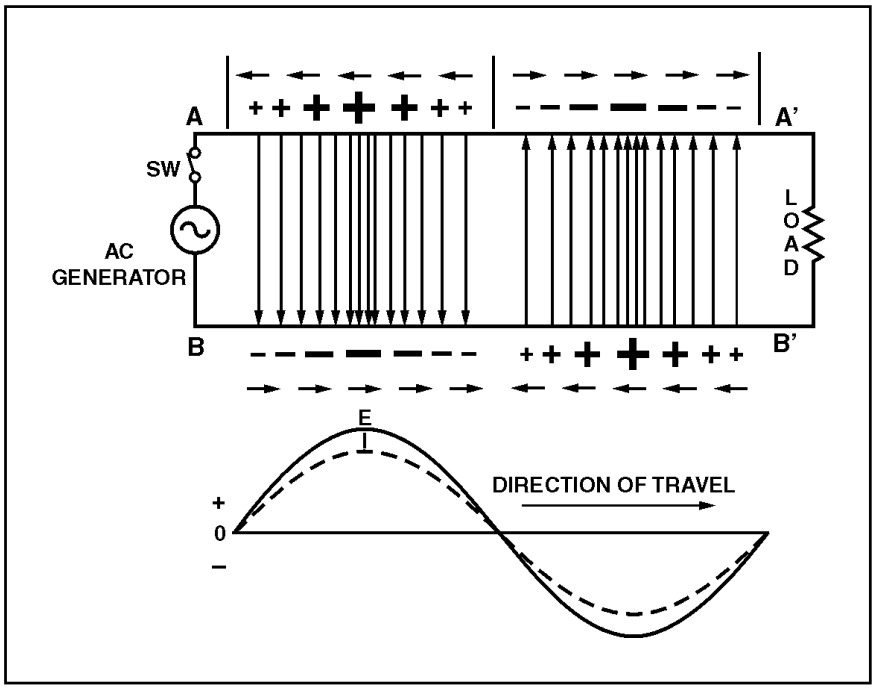

Figure 3-19. AC Voltage Applied to a Transmission Line

3-64. In this illustration the conventional lines of force represent the electric fields. For simplicity, the magnetic fields are not shown. Points of charge are indicated by plus (+) and minus (-) signs, the larger signs indicating points of higher amplitude of both voltage and current. Short arrows indicate direction of current (electron flow). The waveform drawn below the transmission line represents the voltage (E) and current (I) waves. The line is assumed to be infinite in length so there is no reflection. Thus, traveling sinusoidal voltage and current waves continually travel in phase from the generator toward the load, or far end of the line. Waves traveling from the generator to the load are called incident waves. Waves traveling from the load back to the generator are called reflected waves and are explained later in this chapter.

DC Applied to an Infinite Line

3-65. Figure 3-20 shows a battery connected to a circuit that is the equivalent of a transmission line. In this line, the series resistance and shunt conductance are not shown. Also, in the discussion that follows, the line is considered to have no losses.

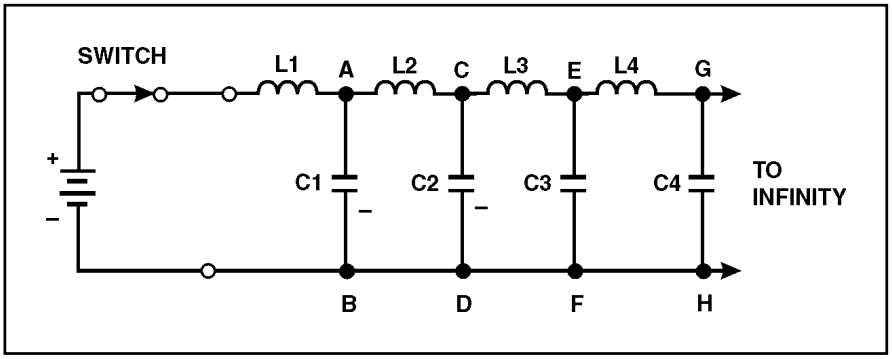

Figure 3-20. DC Applied to an Equivalent Transmission Line

3-66. As the switch shown in figure 3-20 is closed, the battery voltage is applied to the input terminals of the line. Now, C1 has no charge and appears, effectively, as a short circuit across points A and B. The full battery voltage appears across inductor L1. Inductor L1 opposes the change of current (0 now) and limits the rate of charge of C1.

3-67. Capacitor C2 cannot begin to charge until after C1 has charged. No current can flow beyond points A and B until C1 has acquired some charge. As the voltage across C1 increases, current through L2 and C2 charges C2. This action continues down the line and charges each capacitor, in turn, to the battery voltage. Thus, a voltage wave is traveling along the line. Beyond the wavefront, the line is uncharged. Because the line is infinitely long, there will always be more capacitors to be charged, and current will not stop flowing. Thus, current will flow indefinitely in the line.

3-68. Notice that current flows to charge the capacitors along the line. The flow of current is not advanced along the line until a voltage is developed across each preceding capacitor. In this manner voltage and current move down the line together in phase.

AC Applied to an Infinite Line

3-69. An RF line displays similar characteristics when an AC voltage is applied to its sending end or input terminals. In figure 3-21, view A, an AC voltage is applied to the line represented by the circuit shown.

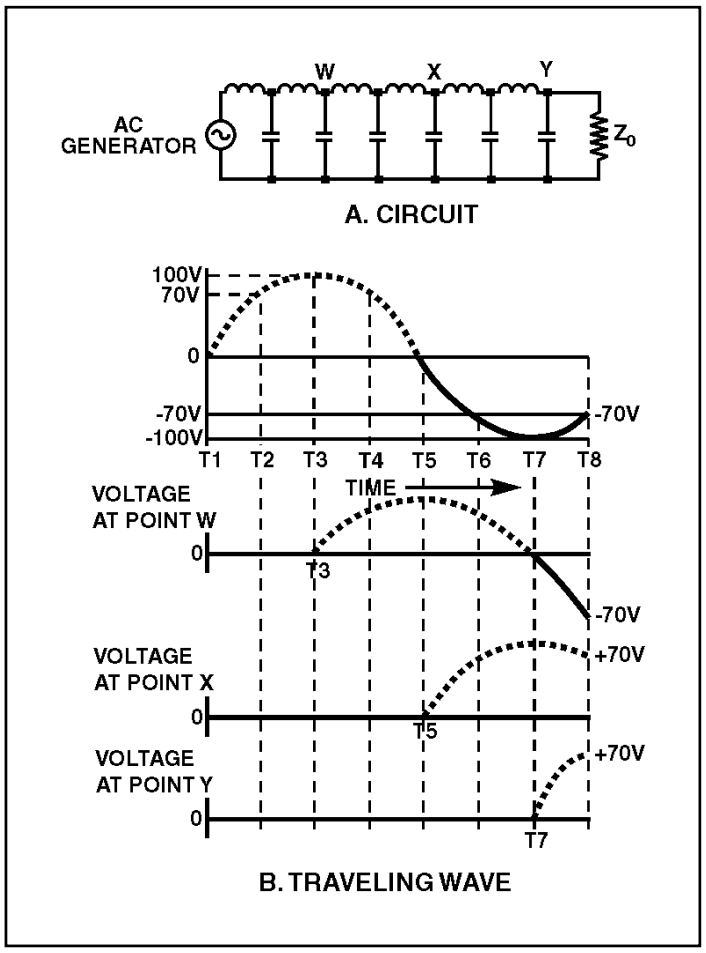

Figure 3-21. AC Applied to an Equivalent Transmission Line

3-70. In figure 3-21, view B, the generator voltage starts from zero (T1) and produces the voltage shown. As soon as a small voltage change is produced, it starts its journey down the line while the generator continues to produce new voltages along a sine curve. At T2 the generator voltage is 70 volts. The voltages still move along the line until, at T3, the first small change arrives at point W, and the voltage at that point starts increasing. At T5, the same voltage arrives at point X on the line. Finally, at T7, the first small change arrives at the receiving end of the line. Meanwhile, all the changes in the sine wave produced by the generator pass each point in turn. The amount of time required for the changes to travel the length of the line is the same as that required for a DC voltage to travel the same distance.

3-71. At T7, the voltage at the various points on the line is as follows:

- At the generator: –100 V
- At point W: 0 V
- At point X: +100 V
- At point Y: 0 V

3-72. If these voltages are plotted along the length of the line, the resulting curve is like the one shown in figure 3-22, view A. Note that such a curve of instantaneous voltages resembles a sine wave. The changes in voltage that occur between T7 and T8 are as follows:

- At the generator: Rise from –100 V to –70 V
- At point W: Drop from 0 V to –70 V
- At point X: Drop from +100 V to +70 V
- At point Y: Rise from 0 V to +70 V

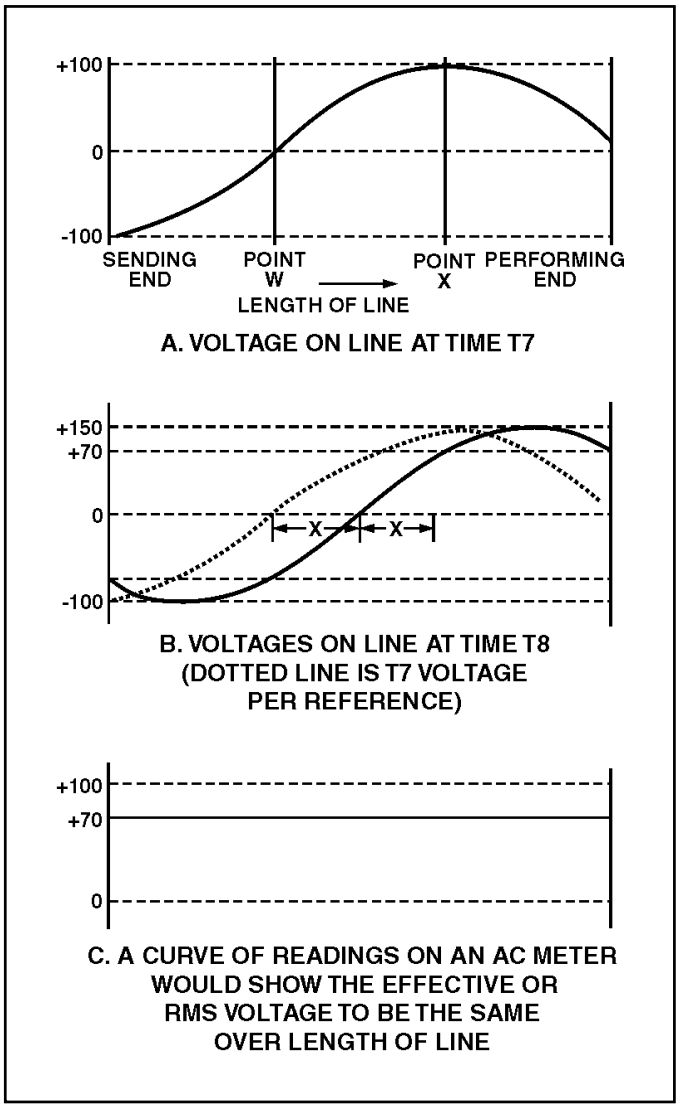

Figure 3-22. Instantaneous Voltages along a Transmission Line

3-73. A plot of these new voltages produces the solid curve shown in figure 3-22, view B. For reference, the curve from T7 is drawn as a dotted line. The solid curve has exactly the same shape as the dotted curve, but has moved to the right by the distance X. Another plot at T9 would show a new curve similar to the one at T8, but moved to the right by the distance Y.

3-74. By analyzing the points along the graph just discussed, you should be able to see that the actions associated with voltage changes along an RF line are as follows:

- All instantaneous voltages of the sine wave produced by the generator travel down the line in the order they are produced.
- At any point, a sine wave can be obtained if all the instantaneous voltages passing the point are plotted. An oscilloscope can be used to plot these values of instantaneous voltages against time.
- The instantaneous voltages (oscilloscope displays) are the same in all cases except that a phase difference exists in the displays seen at different points along the line. The phase changes continually with respect to the generator until the change is 360 degrees over a certain length of line.
- All parts of a sine wave pass every point along the line. A plot of the readings of an AC meter (which reads the effective value of the voltage over a given time) taken at different points along the line shows that the voltage is constant at all points (see figure 3-22, view C).
- Because the line is terminated with a resistance equal to Z_0, the energy arriving at the end of the line is absorbed by the resistance.

VELOCITY OF WAVE PROPAGATION

3-75. If a voltage is initially applied to the sending end of a line, that same voltage will appear later some distance from the sending end. This is true regardless of any change in voltage, whether the change is a jump from zero to some value or a drop from some value to zero. The voltage change will be conducted down the line at a constant rate.

3-76. Recall that the inductance of a line delays the charging of the line capacitance. The velocity of propagation is therefore related to the values of L and C. If the inductance and capacitance of the RF line are known, the time required for any waveform to travel the length of the line can be determined. To see how this works, observe the following relationship:

$$Q = IT$$

This formula shows that the total charge or quantity is equal to the current multiplied by the time the current flows. Also—

$$Q = CE$$

This formula shows that the total charge on a capacitor is equal to the capacitance multiplied by the voltage across the capacitor.

3-77. If the switch in figure 3-23 is closed for a given time, the quantity (Q) of electricity leaving the battery can be computed by using the equation Q = IT. The electricity leaves the battery and goes into the line, where a charge is built up on the capacitors. The amount of this charge is computed by using the equation Q = CE.

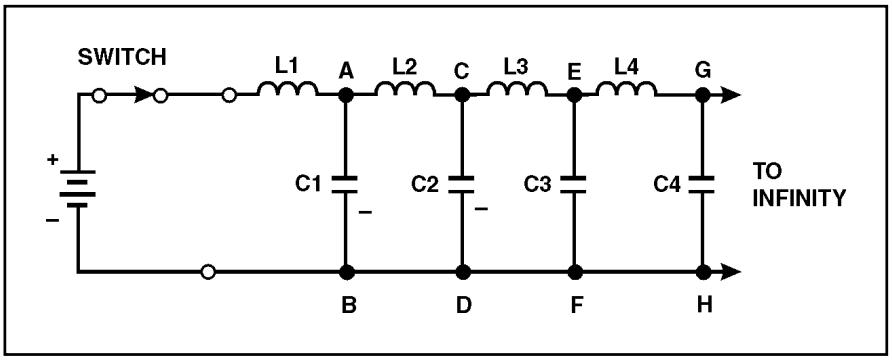

Figure 3-23. DC Applied to an Equivalent Transmission Line

3-78. Because none of the charge is lost, the total charge leaving the battery during T is equal to the total charge on the line. Therefore:

$$Q = IT = CE$$

3-79. As each capacitor accumulates a charge equal to CE, the voltage across each inductor must change. As C1 in figure 3-23 charges to a voltage of E, point A rises to a potential of E volts while point B is still at zero volts. This makes E appear across L2. As C2 charges, point B rises to a potential of E volts as did point A. At this time, point B is at E volts and point C rises. Thus, there is a continuing action of voltage moving down the infinite line.

3-80. In an inductor, these circuit components are related, as shown in the formula—

$$E = L \left(\frac{\Delta I}{\nabla T} \right)$$

3-81. 1-79. This shows that the voltage across the inductor is directly proportional to inductance and the change in current, but inversely proportional to a change in time. Because current and time start from zero, the change in time (ΔT) and the change in current (ΔI) are equal to the final time (T) and final current (I). For this case the equation becomes:

$$ET = LI$$

3-82. If voltage E is applied for time (T) across the inductor (L), the final current (I) will flow. The following equations show how T, L, and C are related:

$$ET = LI$$

$$IT = CE$$

3-83. For convenience, you can find T in terms of L and C by multiplying the left and right members of each of the above equations, and solving for T, as follows:

$$(IT)(ET) = (CE)(LI)$$

$$EIT^2 = LCEI$$

$$T^2 = LC$$

$$T = \sqrt{LC}$$

3-84. This final equation is used for finding the time required for a voltage change to travel a unit length, because L and C are given in terms of unit length. The velocity of the waves may be found by the following equation, where D is the physical length of a unit:

$$v = \frac{D}{T} \text{ Or } v = \frac{D}{\sqrt{LC}}$$

3-85. This is the rate at which the wave travels over a unit length. The units of L and C are henrys and farads, respectively. T is in seconds per unit length and V is in unit lengths per second.

DETERMINING CHARACTERISTIC IMPEDANCE

3-86. As previously discussed, an infinite transmission line exhibits a definite input impedance. This impedance is the characteristic impedance and is independent of line length. The exact value of this impedance is the ratio of the input voltage to the input current. If the line is infinite or is terminated in a resistance equal to the characteristic impedance, voltage and current waves traveling the line are in phase. Recall the following equations:

$$ET = LI$$

$$IT = CE$$

To determine the characteristic impedance or voltage-to-current ratio, use the following procedure:

Divide the equations:

$$ET = LI \text{ and } IT = CE$$

$$\frac{ET}{IT} = \frac{LI}{CE}$$

Multiply the result by $\frac{E}{I}$

$$\frac{E^2T}{I^2T} = \frac{LIE}{CEI}$$

Simplify:

$$\frac{E^2}{I^2} = \frac{L}{C}$$

Take the square root:

$$\frac{E}{I} = \sqrt{\frac{L}{C}} = Z_0 \text{ (characteristic impedance)}$$

3-87. A problem using this equation illustrates how to determine the characteristics of a transmission line.

Assume that the line shown in figure 3-23 is 1,000 feet long. A 100-foot (approximately 30.5 meter) section is measured to determine L and C. The section is found to have an inductance of 0.25 millihenry and a capacitance of 1000 picofarads. Find the characteristic impedance of the line and the velocity of the wave on the line. The characteristic impedance is—

$$Z_0 = \sqrt{LC}$$

$$Z_0 = \sqrt{\frac{0.25 \times 10^{-3}}{1000 \times 10^{-12}}}$$

$$Z_0 = \sqrt{0.25 \times 10^{6}}$$

$$Z_0 = 0.5 \times 10^{3}$$

$$Z_0 = 500\Omega$$

If any other unit length had been considered, the values of L and C would be different, but their ratio would remain the same as would the characteristic impedance.

The formula for T is:

$$T = \sqrt{LC}$$

$$T = \sqrt{0.25 \times 10^{-3} \times 1000 \times 10^{-12}}$$

$$T = \sqrt{0.25 \times 10^{-12}}$$

$$T = 0.5 \times 10^{-6} \text{ second}$$

$$T = 0.5 \text{ microsecond}$$

The formula for the velocity of a wave is:

$$V = \frac{D}{T}$$

$$V = \frac{100 \text{ feet}}{0.5 \times 10^{-6} \text{ second}}$$

$$V = 200 \times 10^{6} \text{ feet/second}$$

$$V = 200{,}000{,}000 \text{ feet/second}$$

REFLECTIONS ON A TRANSMISSION LINE

3-88. Transmission line characteristics are based on an infinite line. A line cannot always be terminated in its characteristic impedance because it is sometimes operated as an open-ended line and at other times as a short-circuit at the receiving end. If the line is open-ended, it has a terminating impedance that is infinitely large. If a line is not terminated in characteristic impedance (Z_0), it is said to be finite.

3-89. When a line is not terminated in characteristic impedance, the incident energy is not absorbed but is returned along the only path available—the

transmission line. Thus, the behavior of a finite line may be quite different from that of the infinite line.

Reflection of DC Voltage from an Open Circuit

3-90. The equivalent circuit of an open-ended transmission line is shown in figure 3-24, view A. Again, losses are to be considered as negligible, and L is lumped in one branch. Assume that (1) the battery in this circuit has an internal impedance equal to the characteristic impedance of the transmission line ($Z_i = Z_0$); (2) the capacitors in the line are not charged before the battery is connected; and (3) because the line is open-ended, the terminating impedance is infinitely large.

3-91. When the battery is connected to the sending end as shown in figure 3-24, view A, a negative voltage moves down the line. This voltage charges each capacitor, in turn, through the preceding inductor. Because Z_i equals Z_0, one-half the applied voltage will appear across the internal battery impedance, Z_i, and one-half across the impedance of the line, Z_0. Each capacitor is then charged to E/2 (view B). When the last capacitor in the line is charged, there is no voltage across the last inductor and current flow through the last inductor stops. With no current flow to maintain it, the magnetic field in the last inductor collapses and forces current to continue to flow in the same direction into the last capacitor. Because the direction of current has not changed, the capacitor charges in the same direction, thereby increasing the charge in the capacitor. Because the energy in the magnetic field equals the energy in the capacitor, the energy transfer to the capacitor doubles the voltage across the capacitor. The last capacitor is now charged to E volts and the current in the last inductor drops to zero.

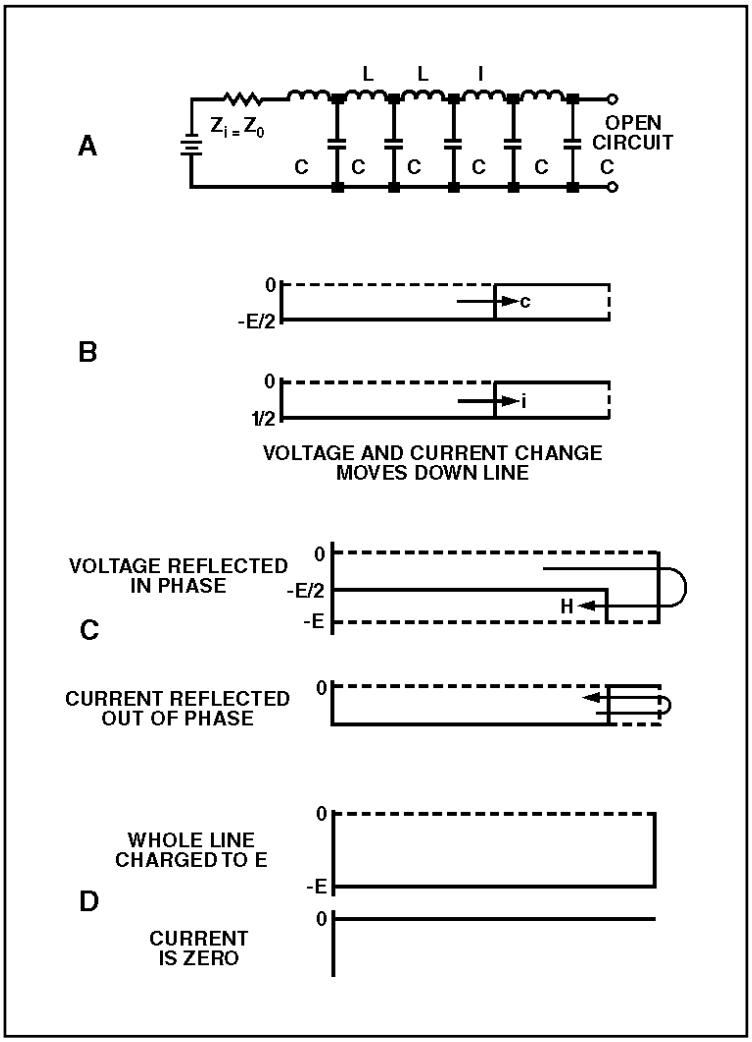

Figure 3-24. Reflection from an Open-Ended Line

3-92. At this point, the same process takes place with the next to the last inductor and capacitor. When the magnetic field about the inductor collapses, current continues to flow into the next to the last capacitor, charging it to E volts. This action continues backward down the line until the first capacitor has been fully charged to the applied voltage. This change of voltage, moving backward down the line, can be thought of in the following manner. The voltage, arriving at the end of the line, finds no place to go and returns to the sending end with the same polarity (figure 3-24, view C). Such action is called reflection.

3-93. When a reflection of voltage occurs on an open-ended line, the polarity is unchanged. The voltage change moves back to the source, charging each capacitor in turn until the first capacitor is charged to the source voltage and the action stops (figure 3-24, view D). As each capacitor is charged, current in each inductor drops to zero, effectively reflecting the current with the opposite polarity (view C). Reflected current of opposite polarity cancels the original current at each point, and the current drops to zero at that point.

When the last capacitor is charged, the current from the source stops flowing (view D).

3-94. Important facts to remember in the reflection of DC voltages in open-ended lines are—

- Voltage is reflected from an open end without change in polarity, amplitude, or shape.
- Current is reflected from an open end with opposite polarity and without change in amplitude or shape.

Reflection of DC Voltage from a Short Circuit

3-95. A short-circuited line affects voltage change differently than the way an open-circuited line affects it. The voltage across a perfect short circuit must be zero; therefore, no power can be absorbed in the short, and the energy is reflected toward the generator.

3-96. The initial circuit is shown in figure 3-25, view A. The initial voltage and current waves (view B) are the same as those given for an infinite line. In a short-circuited line the voltage change arrives at the last inductor in the same manner as the waves on an open-ended line. In this case, however, there is no capacitor to charge. The current through the final inductor produces a voltage with the polarity shown in view C. When the field collapses, the inductor acts as a battery and forces current through the capacitor in the opposite direction, causing it to discharge (view D). Because the amount of energy stored in the magnetic field is the same as that in the capacitor, the capacitor discharges to zero.

3-97. Now there is no voltage to maintain the current through the next to the last inductor. Therefore, this inductor discharges the next to the last capacitor.

3-98. As each capacitor is discharged to zero, the next inductor effectively becomes a new source of voltage. The amplitude of each of these voltages is equal to E/2, but the polarity is the opposite of the battery at the input end of the line. The collapsing field around each inductor, in turn, produces a voltage that forces the current to continue flowing in the same direction, adding to the current from the source to make it 2I. This action continues until all the capacitors are discharged (view E).

3-99. Reflected waves from a short-circuited transmission line are characterized as follows:

- The reflected voltage has the opposite polarity but the same amplitude as the incident wave.
- The reflected current has the same polarity and the same amplitude as the incident current.

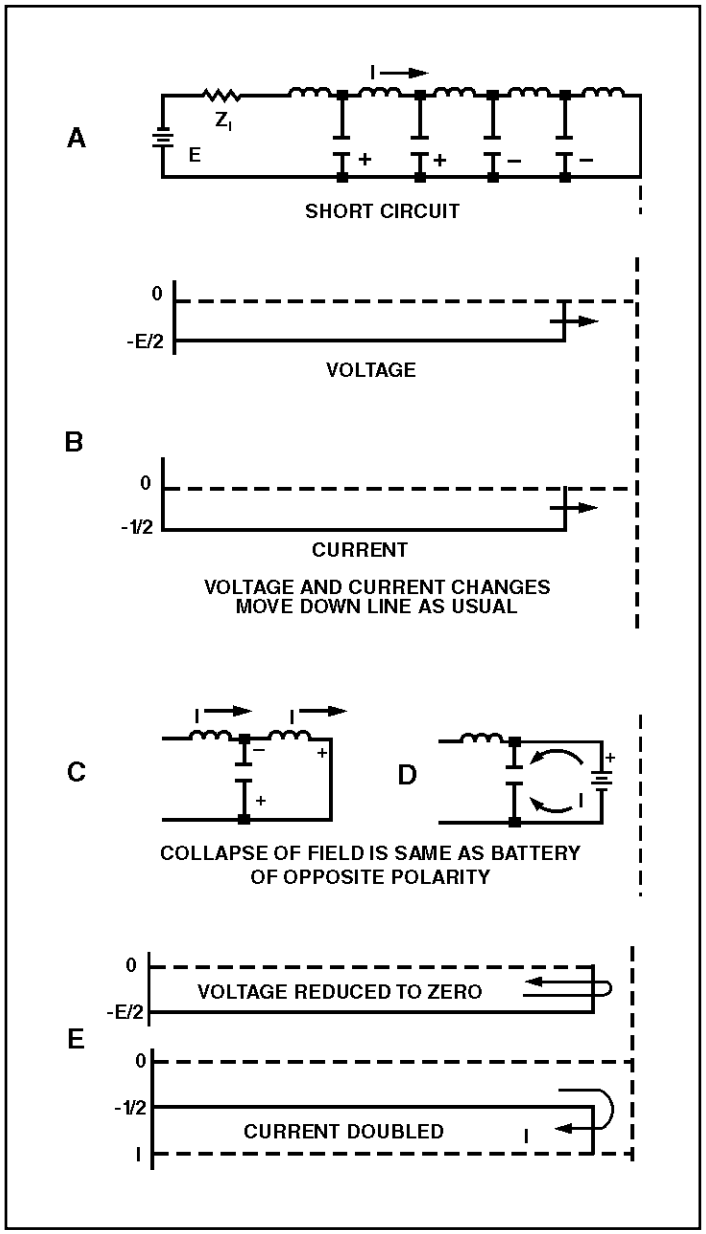

Figure 3-25. Reflection from a Short-Circuited Line

Reflection of AC Voltage from an Open Circuit

3-100. In most cases where RF lines are used, the voltages applied to the sending end are AC voltages. The action at the receiving end of the line is exactly the same for AC as for DC. In the open-ended line, as shown in figure 3-26, view A, the generated AC voltage is distributed along the line, shown in view B. This voltage is distributed in such a way that as each instantaneous voltage arrives at the end, it is reflected with the same polarity and amplitude. When AC is used, this reflection is in phase. Each of the reflected voltages travels back along the line until it reaches the generator. If the generator impedance is the same as the line impedance, energy arriving at the generator is absorbed and not reflected again. Now two voltages are on the line.

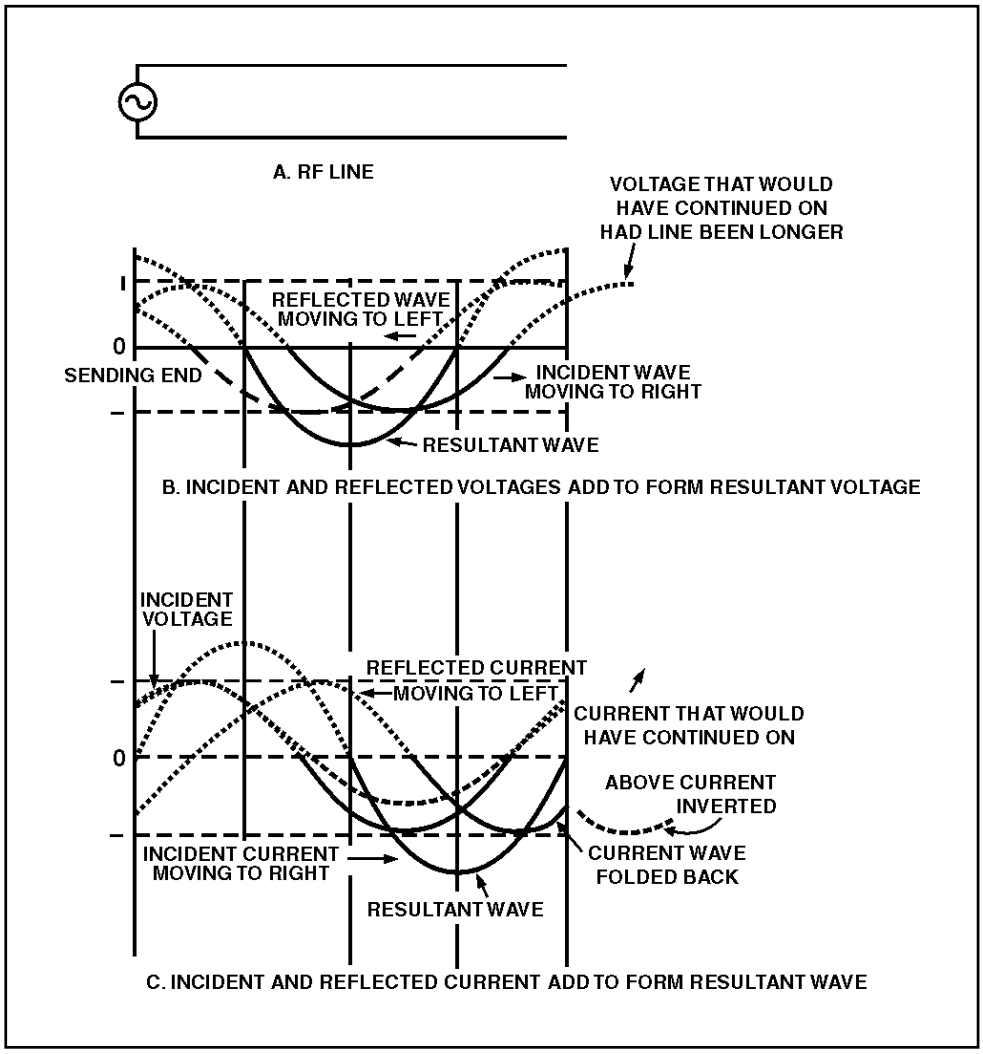

Figure 3-26. Formation of Standing Waves

3-101. View B of figure 3-26 shows how two waves of the same frequency and amplitude moving in opposite directions on the same conductor will combine to form a resultant wave. The small solid line is moving steadily from left to right and is the incident wave (from the source). The broken-line waveform is moving from right to left and is the reflected wave. The resultant waveform, the heavy line, is found by algebraically adding instantaneous values of the two waveforms. The resultant waveform has an instantaneous peak amplitude that is equal to the sum of the peak amplitudes of the incident and reflected waves. Because most indicating instruments are unable to separate these voltages, they show the vector sum. An oscilloscope is usually used to study the instantaneous voltages on RF lines.

3-102. Because two waves of voltage are moving on the line, you need to know how to distinguish between the two. The voltages moving toward the receiving end are called incident voltages, and the whole waveshape is called the incident wave. The wave moving back to the sending end after reflection

is called the reflected wave. The resultant voltage curve (view B of figure 3-26) shows that the voltage is maximum at the end of the line, a condition that occurs across an open circuit.

3-103. Another step in investigating the open-circuited RF line is to see how the current waves act. The incident current wave is the solid line in figure 3-26, view C. The voltage is represented by the dotted line. The current is in phase with the voltage while traveling toward the receiving end. At the end of the line, the current is reflected in the opposite polarity; that is, it is shifted 180 degrees in phase, but its amplitude remains the same. Dashed lines show the reflected wave of current in view C. The heavy-line curve represents the sum of the two instantaneous currents and is the resultant wave. Notice that current is zero at the end of the line. This is reasonable, because there can be no current flow through an open circuit.

3-104. Views B and C of figure 3-26 show the voltage and current distribution along a transmission line at a point about one-eighth wavelength after a maximum voltage or current reaches the end of the line. Because the instantaneous values are continuously changing during the generation of a complete cycle, a large number of these pictures are required to show the many different relationships.

3-105. Figure 3-27 shows the incident and reflected waveshapes at several different times. The diagrams in the left column of figure 3-27 (representing voltage) show the incident wave and its reflection without change in polarity. In figure 3-27, waveform (1), the incident wave and the reflected wave are added algebraically to produce the resultant wave indicated by the heavy line. In waveform (2), a zero point preceding the negative-going cycle of the incident wave is at the end of the line. The reflected wave and incident wave are 180 degrees out of phase at all points. (The reflected wave is the positive cycle that just preceded the negative cycle now approaching the end of the line.) The resultant of the incident and reflected waves is zero at all points along the line. In waveform (3), the waves have moved 1/8 wavelength along the line; the incident wave has moved 45 degrees to the right, and the reflected wave has moved 45 degrees to the left. The resultant voltage, shown by the heavy line, has a maximum negative at the end of the line and a maximum positive 1/2 wavelength from the end of the line.

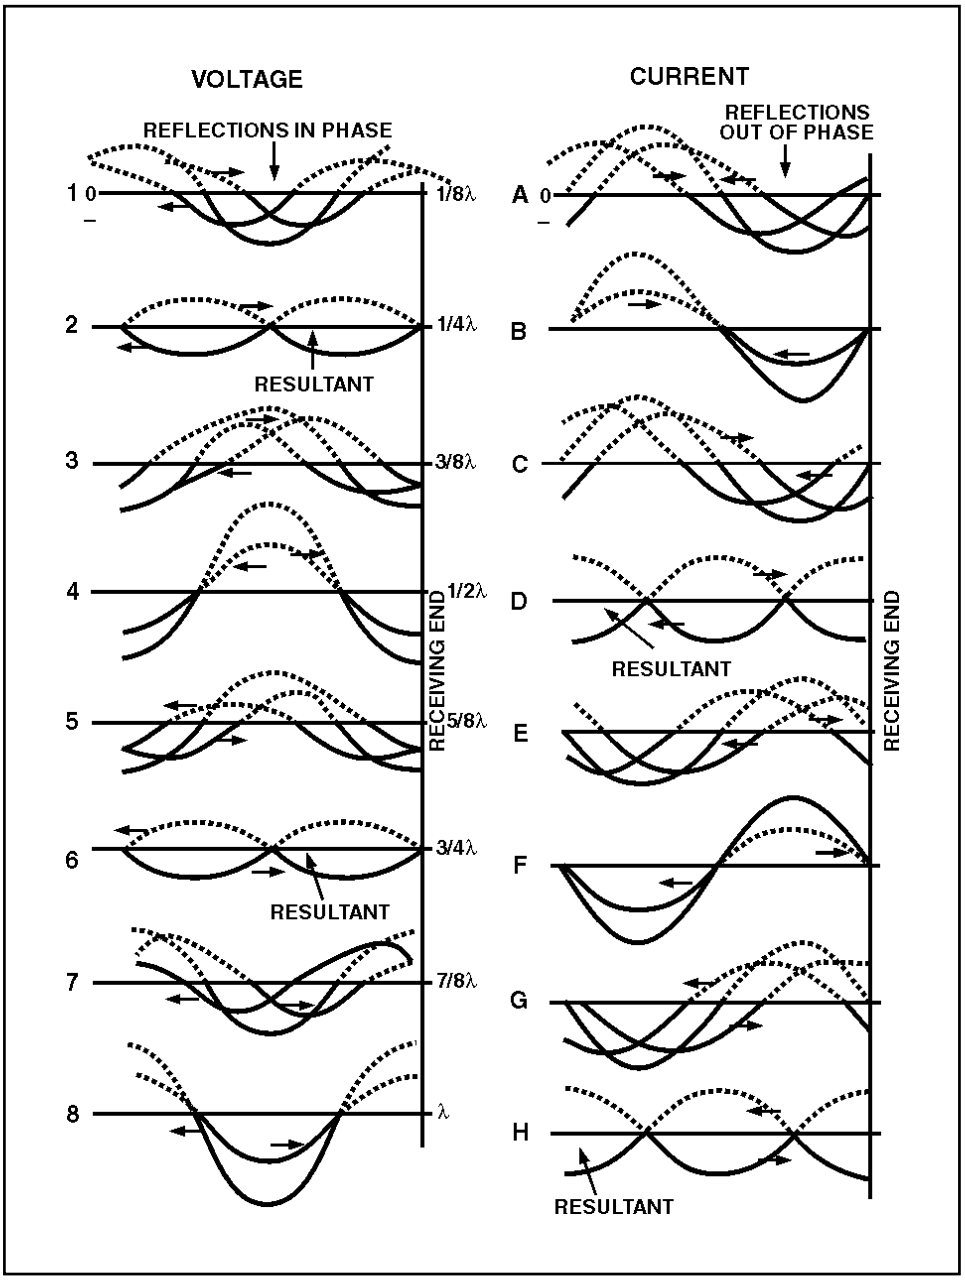

Figure 3-27. Instantaneous Values of Incident and Reflected Waves on an Open-Ended Line

3-106. In waveform (4) of figure 3-27, the incident wave is at a maximum negative value at the end of the line. The wave has moved another 45 degrees to the right from the wave in the preceding illustration. The reflected wave has also moved 45 degrees, but to the left. The reflected wave is in phase with the incident wave. The resultant of these two waves, shown by the dark line, again has a negative maximum at the end of the line and a positive maximum 1/2λ from the end of the line. Notice that these maxima have a greater amplitude than those in waveform (3).

3-107. In waveform (5) of figure 3-27, the incident wave has moved another 45 degrees to the right and the reflected wave 45 degrees to the left. The resultant again is maximum negative at the end and positive maximum 1/2 wavelength from the end. The maxima are lower than those in waveform (4). In waveform (6), the incident and reflected wave have moved another 1/8λ. The two waves again are 180 degrees out of phase, giving a resultant wave with no amplitude. The incident and reflected waves continue moving in opposite directions, adding to produce the resultant waveshapes shown in waveforms (7) and (8). Notice that the maximum voltage in each resultant wave is at the end and 1/2λ from the end.

3-108. Study each part of figure 3-27 carefully and you will get a clear picture of how the resultant waveforms of voltage are produced. You will also see that the resultant voltage wave on an open-ended line is always zero at 1/4λ and 3/4λ from the end of the transmission line. Because the zero and maximum points are always in the same place, the resultant of the incident and the reflected wave is called a standing wave of voltage.

3-109. The right-hand column in figure 3-27 shows the current waveshapes on the open-ended line. Because the current is reflected out of phase at an open end, the resultant waveshapes differ from those for voltage. The two out-of-phase components always cancel at the end of the transmission line, so the resultant is always zero at that point. If you check all the resultant waveshapes shown in the right-hand column of figure 3-27, you will see that a zero point always occurs at the end and at a point 1/2λ from the end. Maximum voltages occur 1/4λ and 3/4λ from the end.

3-110. When an AC meter is used to measure the voltages and currents along a line, the polarity is not indicated. If you plot all the current and voltage readings along the length of the line, you will get curves like the ones shown in figure 3-28. Notice that all are positive. These curves are the conventional method of showing current and voltage standing waves on RF lines.

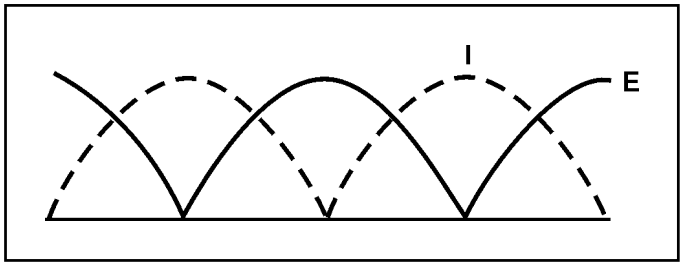

Figure 3-28. Conventional Picture of Standing Waves

3-111. When an RF line is terminated in a short circuit, reflection is complete, but the effect on voltage and current differs from that in an open-ended line. Voltage is reflected in opposite phase, while current is reflected in phase. Again refer to the series of pictures shown in figure 3-27. However, this time the left column represents current, because it shows reflection in phase; and the right column of pictures now represents the voltage changes on the shorted line, because it shows reflection out of phase.

3-112. The composite diagram in figure 3-29 shows all resultant curves on a full-wavelength section of line over a complete cycle. Notice that the amplitude of the voltage varies between zero and maximum in both directions at the center and at both ends as well, but one-fourth of the distance from each end the voltage is always zero. The resultant waveshape is referred to as a standing wave of voltage. Standing waves, then, are caused by reflections, which occur only when the line is not terminated in its characteristic impedance.

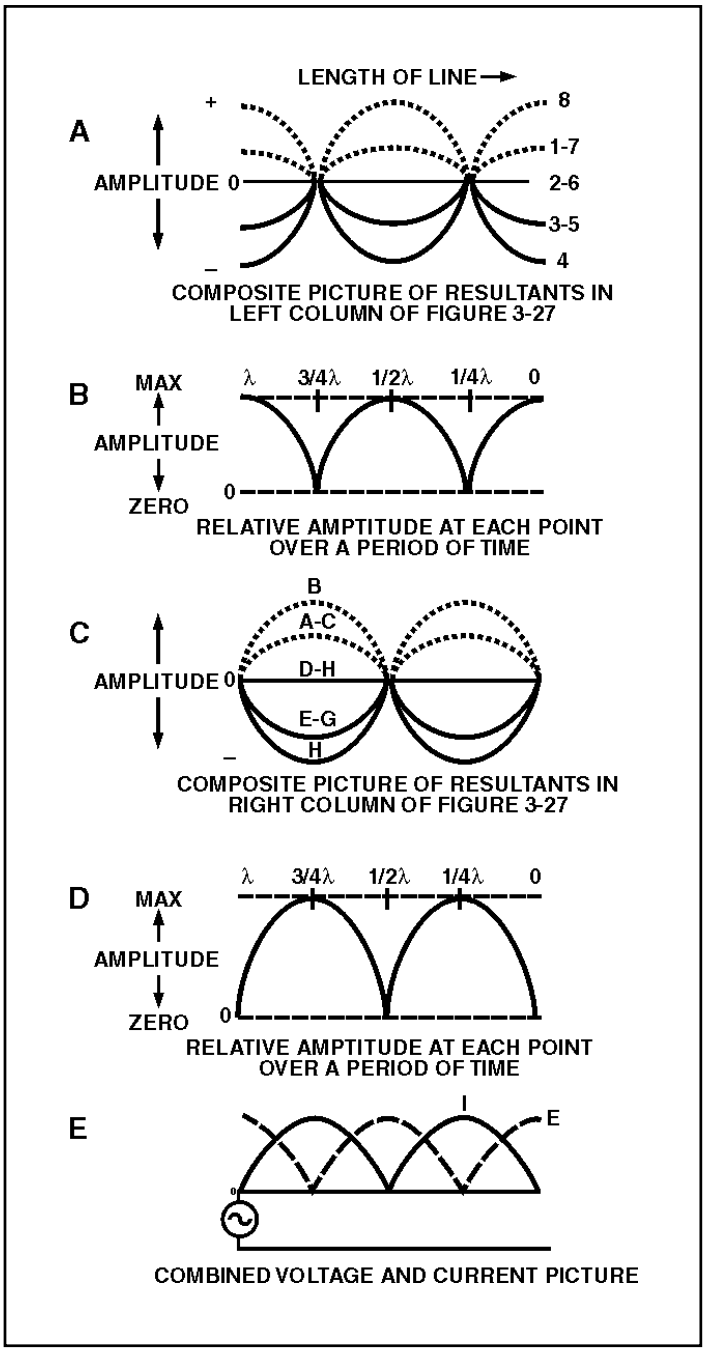

Figure 3-29. Composite Results of Instantaneous Waves

3-113. The voltage at the center and the ends varies at a sinusoidal rate between the limits shown. At the one-fourth and three-fourths points, the voltage is always zero. A continuous series of diagrams such as these is difficult to see with conventional test equipment, which reads the effective or average voltage over several cycles. The curve of amplitude over the length of line for several cycles is shown in figure 3-29, view B. A meter will read zero at the points shown and will show a maximum voltage at the center, no matter how many cycles pass.

3-114. As shown in figure 3-29, view D, the amplitude varies along the length of the line. In this case it is zero at the end and center but maximum at the one-fourth and three-fourths points. The entire diagram of the open-ended line conditions is shown in view E. The standing waves of voltage and current appear together. Observe that one is maximum when the other is minimum. The current and voltage standing waves are one-quarter cycle, or 90 degrees, out of phase with one another.

Reflection of AC Voltage from a Short Circuit

3-115. Reflection is complete when an RF line is terminated in a short circuit, but the effect on voltage and current differs from the effect obtained in an open-ended line. Voltage is reflected in opposite phase, while current is reflected in phase. Again look at the series of diagrams in figure 3-27. The left column represents current, and the right column shows voltage changes on the shorted line. The standard representation of standing waves on a shorted line is shown in figure 3-30; the voltage is a solid line, and the current is a dashed line. The voltage is zero at the end and center (1/2λ) and maximum at the 1/4λ and 3/4λ points, while the current is maximum at the end and center and minimum at the 1/4λ and 3/4λ points.

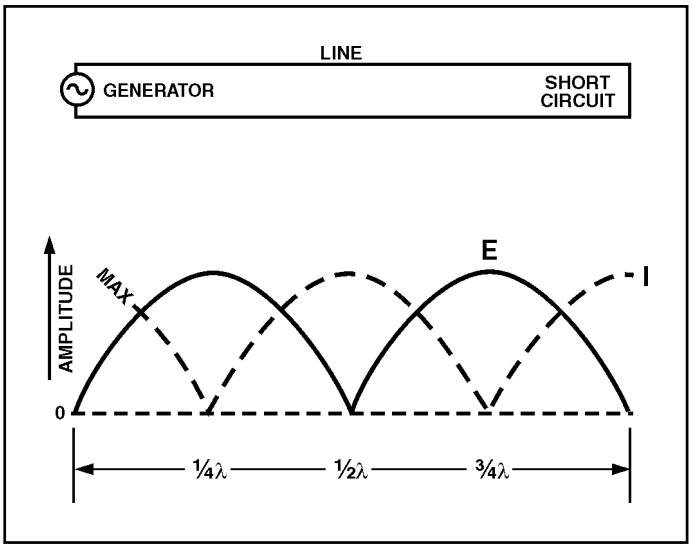

Figure 3-30. Standing Waves on a Shorted Line

3-116. As previously discussed, there are several differences between open and shorted lines in the voltage and current waves on transmission lines. Basic differences also appear in the standing-wave patterns for open and shorted lines. You can see these differences by comparing figure 3-29, view E

and figure 3-30. Notice that the current and voltage standing waves are shifted 90 degrees with respect to the termination. At the open end of a line, voltage is maximum (zero if there are no losses in the line). At a short circuit, current is maximum and voltage is minimum.

TERMINATING A TRANSMISSION LINE

3-117. A transmission line is either nonresonant or resonant. A nonresonant line is a line that has no standing waves of current and voltage. A resonant line is a line that has standing waves of current and voltage.

Nonresonant Lines

3-118. A nonresonant line is either infinitely long or terminated in its characteristic impedance. Because no reflections occur, all the energy traveling down the line is absorbed by the load that terminates the line. Because no standing waves are present, this type of line is sometimes spoken of as a flat line. In addition, because the load impedance of such a line is equal to Z_0, no special tuning devices are required to effect a maximum power transfer; hence, the line is also called an untuned line.

Resonant Lines

3-119. A resonant line has a finite length and is not terminated in its characteristic impedance. Therefore reflections of energy do occur. The load impedance is different from the Z_0 of the line; therefore, the input impedance may not be purely resistive but may have reactive components. Tuning devices are used to eliminate the reactance and to bring about maximum power transfer from the source to the line. Therefore, a resonant line is sometimes called a tuned line. The line also may be used for a resonant or tuned circuit.

3-120. A resonant line is sometimes said to be resonant at an applied frequency. This means that at one frequency the line acts as a resonant circuit. It may act either as a high-resistive circuit (parallel resonant) or as a low-resistive circuit (series resonant). The line may be made to act in this manner by either open- or short-circuiting it at the output end and cutting it to some multiple of a quarter-wavelength.

3-121. At the points of voltage maxima and minima on a short-circuited or open-circuited line, the line impedance is resistive. On a short-circuited line, each point at an odd number of quarter-wavelengths from the receiving end has a high impedance (figure 3-31, view A). If the frequency of the applied voltage to the line is varied, this impedance decreases as the effective length of the line changes. This variation is exactly the same as the change in the impedance of a parallel-resonant circuit when the applied frequency is varied.

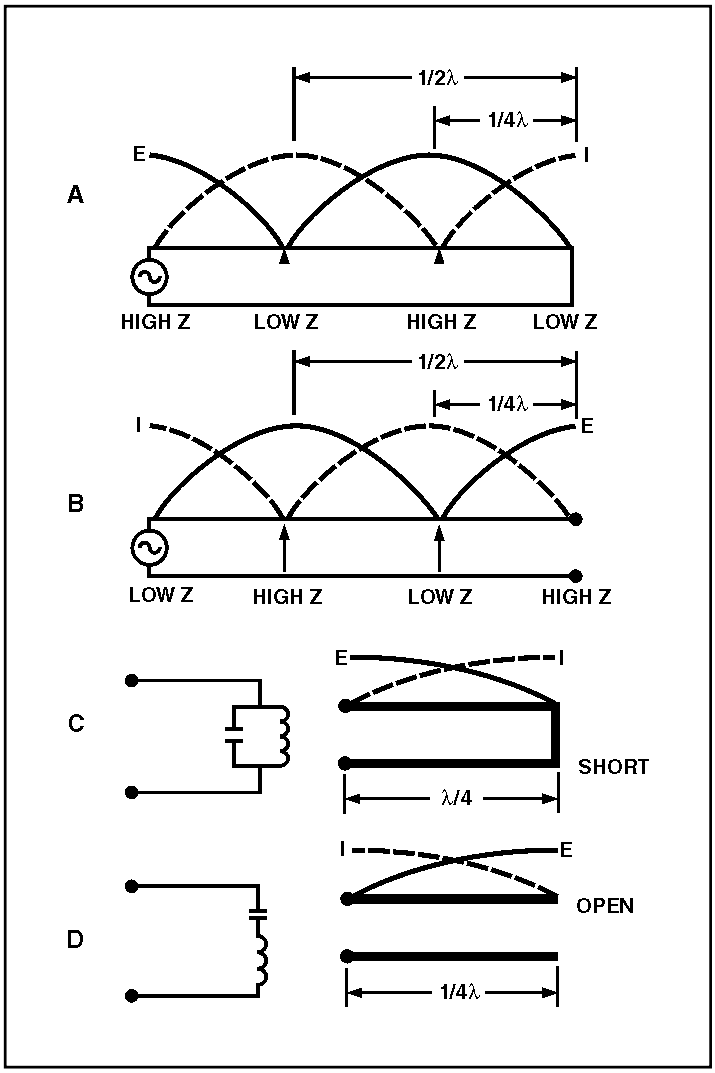

Figure 3-31. Sending-End Impedance of Various Lengths and Terminations

3-122. At all even numbered quarter-wavelength points from the short circuit, the impedance is extremely low. When the frequency of the voltage applied to the line is varied, the impedance at these points increases just as the impedance of a series-resonant circuit varies when the frequency applied to it is changed. The same is true for an open-ended line (figure 3-31, view B), except that the points of high and low impedance are reversed.

3-123. At this point let us review some of the characteristics of resonant circuits so we can see how resonant line sections may be used in place of LC circuits.

3-124. A parallel-resonant circuit has the following characteristics:

- At resonance, the impedance appears as a very high resistance. A loss-free circuit has infinite impedance (an open circuit). Other than at resonance, the impedance decreases rapidly.
- If the circuit is resonant at a point above the generator frequency (the generator frequency is too low), more current flows through the coil than through the capacitor. This happens because X_L decreases with a decrease in frequency, but X_C increases.

3-125. A series-resonant circuit has these characteristics:

- At resonance, the impedance appears as a very low resistance. A loss-free circuit has zero impedance (a short circuit). Other than at resonance, the impedance increases rapidly.
- If the circuit is resonant at a point above the generator frequency (the generator frequency is too low), then X_C is larger than X_L and the circuit acts capacitively.
- If the circuit is resonant at a point below the generator frequency (the generator frequency is too high), then X_L is larger than X_C and the circuit acts inductively.

3-126. Because the impedance a generator sees at the quarter-wave point in a shorted line is that of a parallel-resonant circuit, a shorted quarter-wavelength of line may be used as a parallel-resonant circuit (figure 3-31, view C). An open quarter-wavelength of line may be used as a series-resonant circuit (view D). The Q of such a resonant line is much greater than can be obtained with lumped capacitance and inductance.

Impedance for Various Lengths of Open Lines

3-127. In figure 3-32, the impedance (Z) the generator sees for various lengths of line is shown at the top. The curves above the letters of various heights show the relative value of the impedances presented to the generator for the various line lengths. The circuit symbols indicate the equivalent electrical circuits for the transmission lines at each particular length. The standing waves of voltage and current are shown on each length of line.

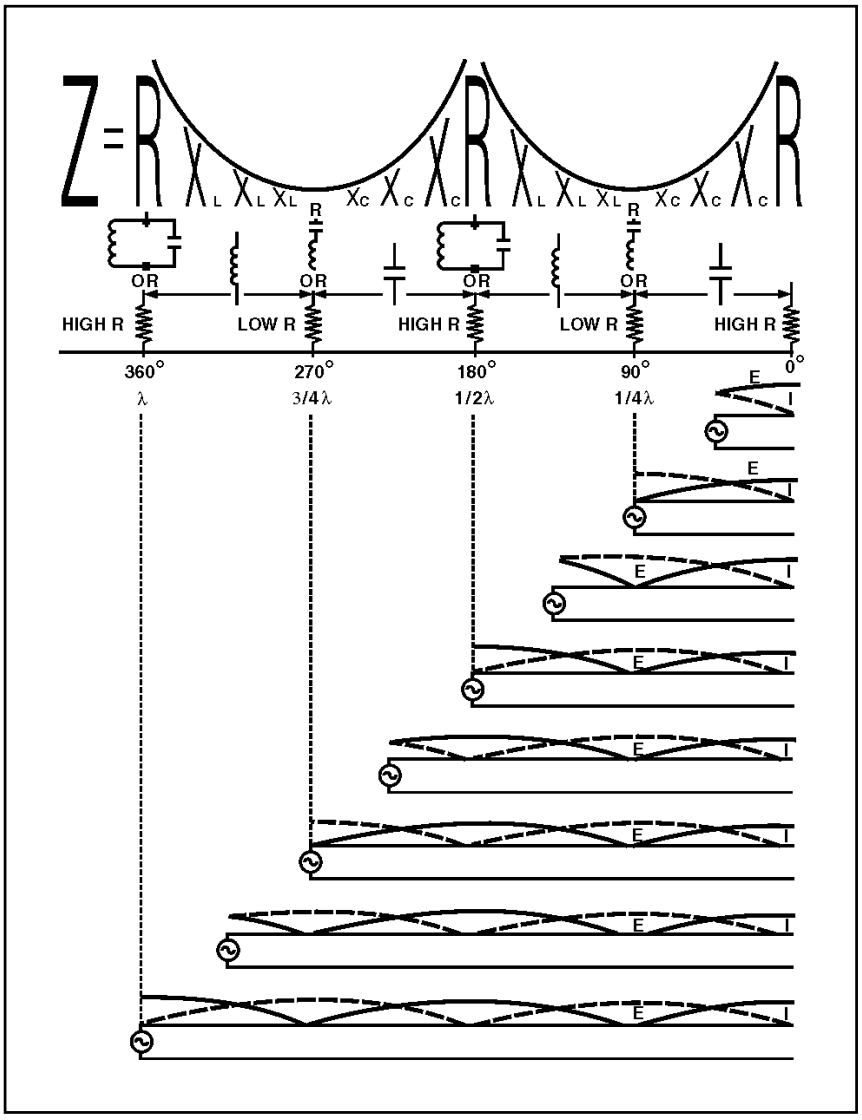

Figure 3-32. Voltage, Current, and Impedance on Open Line

3-128. At all odd quarter-wave points (1/4λ, 3/4λ, etc.), the voltage is minimum, the current is maximum, and the impedance is minimum. Thus, at all odd quarter-wave points, the open-ended transmission line acts as a series-resonant circuit. The impedance is equivalent to a very low resistance, prevented from being zero only by small circuit losses.

3-129. At all even quarter-wave points (1/2λ, 1λ, 3/2λ, etc.), the voltage is maximum, the current is minimum, and the impedance is maximum. Comparison of the line with an LC resonant circuit shows that at an even number of quarter-wavelengths, an open line acts as a parallel-resonant circuit. The impedance is therefore an extremely high resistance.

3-130. In addition, resonant open lines may also act as nearly pure capacitances or inductances. The illustration shows that an open line less than a quarter-wavelength long acts as a capacitance. Also, it acts as an

inductance from 1/4 to 1/2 wavelength, as a capacitance from 1/2 to 3/4 wavelength, and as an inductance from 3/4 to 1 wavelength, and so forth. A number of open transmission lines, with their equivalent circuits, are shown in the illustration.

Impedance of Various Lengths of Shorted Lines

3-131. Refer to figure 3-33 in the following discussion of the shorted line. At the odd quarter-wavelength points, the voltage is high, the current is low, and the impedance is high. Because these conditions are similar to those found in a parallel-resonant circuit, the shorted transmission line acts as a parallel-resonant circuit at these lengths.

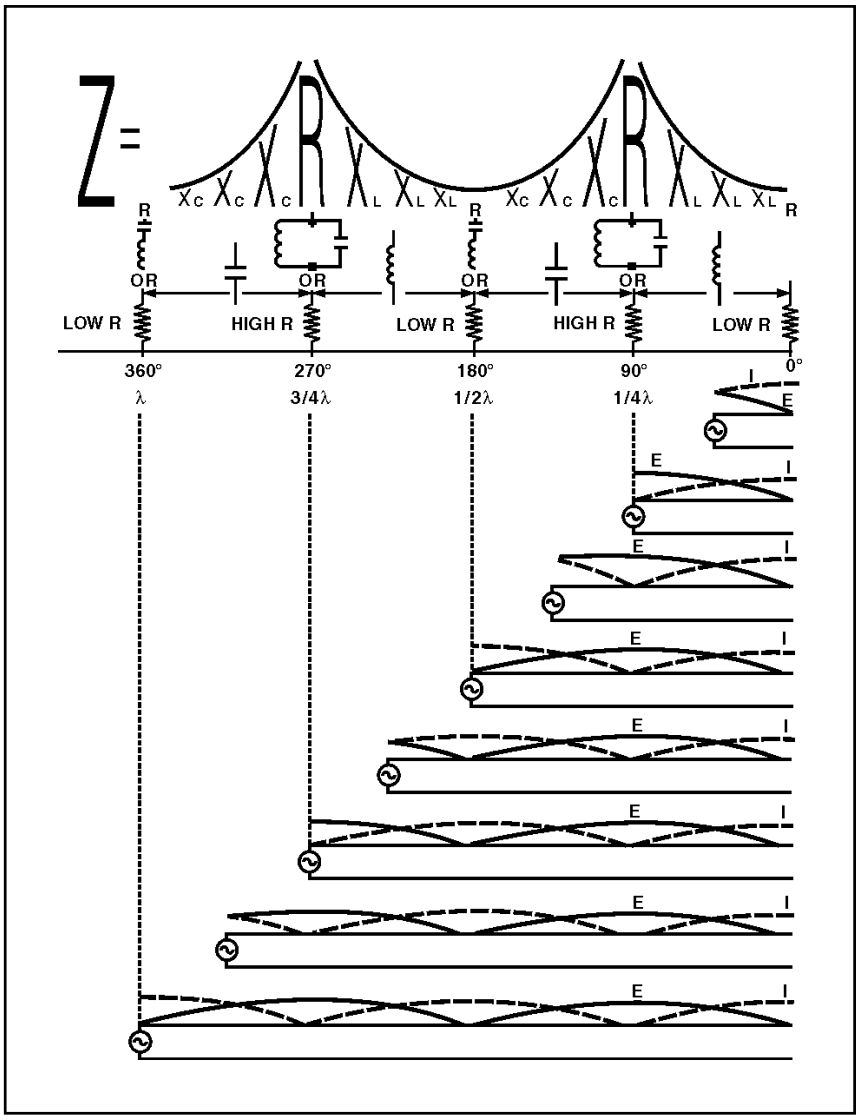

Figure 3-33. Voltage, Current, and Impedance on Shorted Line

3-132. At the even quarter-wave points in figure 3-33, voltage is minimum, current is maximum, and impedance is minimum. Because these characteristics are similar to those of a series-resonant LC circuit, a shorted transmission line whose length is an even number of quarter-wavelengths acts as a series-resonant circuit.

3-133. Resonant shorted lines, like open-end lines, also may act as pure capacitances or inductances. The illustration shows that a shorted line less than 1/4 wavelength long acts as an inductance. A shorted line with a length of from 1/4 to 1/2 wavelength acts as a capacitance. From 1/2 to 3/4 wavelength, the line acts as an inductance; and from 3/4 to 1 wavelength, it acts as a capacitance, and so on. The equivalent circuits of shorted lines of various lengths are shown in the illustration. Thus, properly chosen line segments may be used as parallel-resonant, series-resonant, inductive, or capacitive circuits.

EFFECT OF TERMINATION ON STANDING WAVES

3-134. There is a large variety of terminations for RF lines. Each type of termination has a characteristic effect on the standing waves on the line. From the nature of the standing waves, you can determine the type of termination that produces the waves.

TERMINATION IN Z_0

3-135. Termination in Z_0 (characteristic impedance) will cause a constant reading on an AC meter when it is moved along the length of the line. As illustrated in figure 3-34, view A, the curve—provided there are no losses in the line—will be a straight line. If there are losses in the line, the amplitude of the voltage and current will diminish as they move down the line (view B). The losses are due to DC resistance in the line itself.

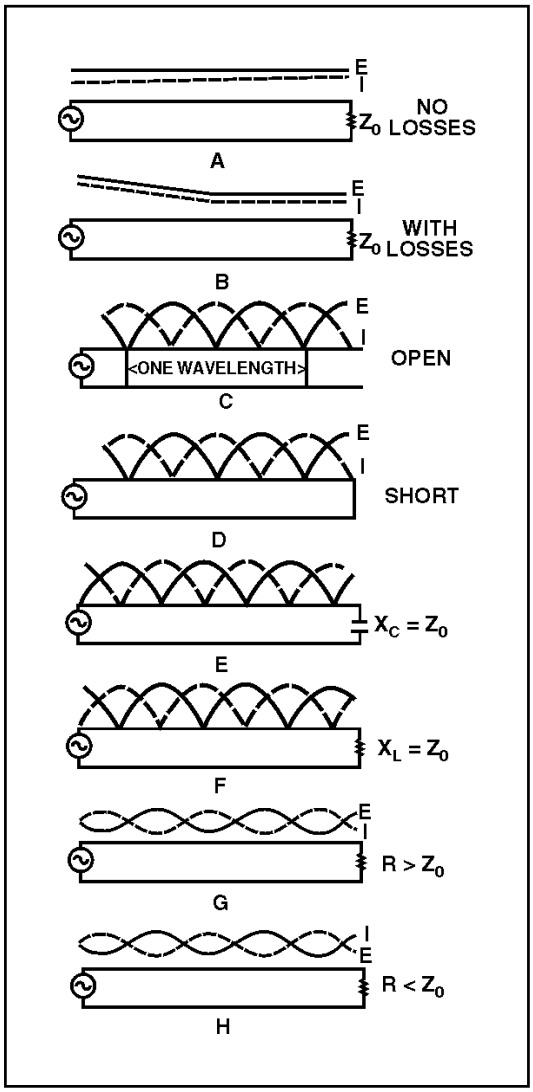

Figure 3-34. Effects of Various Terminations on Standing Waves

TERMINATION IN AN OPEN CIRCUIT

3-136. In an open-circuited RF line (figure 3-34, view C), the voltage is maximum at the end, but the current is minimum. The distance between two adjacent zero current points is 1/2λ, and the distance between alternate zero current points is 1λ. The voltage is zero at a distance of 1/4λ from the end of the line. This is true at any frequency. A voltage peak occurs at the end of the line, at 1/2λ from the end, and at each 1/2λ thereafter.

TERMINATION IN A SHORT CIRCUIT

3-137. On the line terminated in a short circuit, shown in figure 3-34, view D, the voltage is zero at the end and maximum at 1/4λ from the end. The current is maximum at the end, zero at 1/4λ from the end, and alternately maximum and zero every 1/4λ thereafter.

TERMINATION IN CAPACITANCE

3-138. When a line is terminated in capacitance, the capacitor does not absorb energy, but returns all of the energy to the circuit. This means there is 100 percent reflection. The current and voltage relationships are somewhat more involved than in previous types of termination. For this explanation, assume that the capacitive reactance is equal to the characteristic impedance (Z_0) of the line. Current and voltage are in phase when they arrive at the end of the line, but in flowing through the capacitor and the characteristic impedance connected in series, they shift in phase relationship. Current and voltage arrive in phase and leave out of phase. This results in the standing-wave configuration shown in figure 3-34, view E. The standing wave of voltage is minimum at a distance of exactly 1/8λ from the end. If the capacitive reactance is greater than Z_0 (smaller capacitance), the termination looks more like an open circuit; the voltage minimum moves away from the end. If the capacitive reactance is smaller than Z_0, the minimum moves toward the end.

TERMINATION IN INDUCTANCE

3-139. When the line is terminated in an inductance, both the current and voltage shift in phase as they arrive at the end of the line. When X_L is equal to Z_0, the resulting standing waves are as shown in figure 3-34, view F. The current minimum is located 1/8λ from the end of the line. When the inductive reactance is increased, the standing waves appear closer to the end. When the inductive reactance is decreased, the standing waves move away from the end of the line.

TERMINATION IN A RESISTANCE NOT EQUAL TO THE CHARACTERISTIC IMPEDANCE (Z_0)

3-140. Whenever the termination is not equal to Z_0, reflections occur on the line. For example, if the terminating element contains resistance, it absorbs some energy, but if the resistive element does not equal the Z_0 of the line, some of the energy is reflected. The amount of voltage reflected may be found by using the equation:

$$E_R = E_i \left(\frac{R_L - Z_O}{R_L + Z_O} \right)$$

Where:

E_R = the reflected voltage

E_i = the incident voltage

R_L = the terminating resistance

Z_0= the characteristic impedance of the line

3-141. If you try different values of RL in the preceding equation, you will find that the reflected voltage is equal to the incident voltage only when RL equals 0 or is infinitely large. When RL equals Z_0, no reflected voltage occurs. When RL is greater than Z_0, ER is positive, but less than Ei. As RL increases and approaches an infinite value, ER increases and approaches Ei in value. When RL is smaller than Z_0, ER has a negative value. This means that the reflected voltage is of opposite polarity to the incident wave at the termination of the line. As RL approaches zero, ER approaches Ei in value. The smaller the value of ER, the smaller is the peak amplitude of the standing waves and the higher are the minimum values.

TERMINATION IN A RESISTANCE GREATER THAN Z_0

3-142. When RL is greater than Z_0, the end of the line is somewhat like an open circuit; that is, standing waves appear on the line. The voltage maximum appears at the end of the line and also at half-wave intervals back from the end. The current is minimum (not zero) at the end of the line and maximum at the odd quarter-wave points. Because part of the power in the incident wave is consumed by the load resistance, the minimum voltage and current are less than for the standing waves on an open-ended line. Figure 3-34, view G, illustrates the standing waves for this condition.

TERMINATION IN A RESISTANCE LESS THAN Z_0

3-143. When R_L is less than Z_0, the termination appears as a short circuit. The standing waves are shown in figure 3-34, view H. Notice that the line terminates in a current loop (peak) and a voltage node (minimum). The values of the maximum and minimum voltage and current approach those for a shorted line as the value of RL approaches zero.

3-144. A line does not have to be any particular length to produce standing waves; however, it cannot be an infinite line. Voltage and current must be reflected to produce standing waves. For reflection to occur, a line must not be terminated in its characteristic impedance. Reflection occurs on lines terminated in opens, shorts, capacitances, and inductances, because the load absorbs no energy. If the line is terminated in a resistance not equal to the characteristic impedance of the line, some energy will be absorbed and the rest will be reflected.

3-145. The voltage and current relationships for open-ended and shorted lines are opposite to each other, as shown in figure 3-34, views C and D. The points of maximum and minimum voltage and current are determined from the output end of the line, because reflection always begins at that end.

STANDING-WAVE RATIO

3-146. The measurement of standing waves on a transmission line yields information about equipment operating conditions. Maximum power is absorbed by the load when $Z_L = Z_0$. If a line has no standing waves, the termination for that line is correct and maximum power transfer takes place.

3-147. You have probably noticed that the variation of standing waves shows how near the RF line is to being terminated in Z_0. A wide variation in voltage along the length means a termination far from Z_0. A small variation means termination near Z_0. Therefore, the ratio of the maximum to the minimum is a measure of the perfection of the termination of a line. This ratio is called the standing-wave ratio (SWR) and is always expressed in whole numbers. For example, a ratio of 1:1 describes a line terminated in its characteristic impedance (Z_0).

Voltage Standing-Wave Ratio

3-148. The ratio of maximum voltage to minimum voltage on a line is called the voltage standing-wave ratio (VSWR). Therefore—

$$VSWR = \frac{E_{max}}{E_{min}}$$

3-149. The vertical lines in the formula indicate that the enclosed quantities are absolute and that the two values are taken without regard to polarity. Depending on the nature of the standing waves, the numerical value of VSWR ranges from a value of 1 ($Z_L = Z_0$, no standing waves) to an infinite value for theoretically complete reflection. Because there is always a small loss on a line, the minimum voltage is never zero and the VSWR is always some finite value. However, if the VSWR is to be a useful quantity, the power losses along the line must be small in comparison to the transmitted power.

Power Standing-Wave Ratio

3-150. The square of the voltage standing-wave ratio is called the power standing-wave ratio (PSWR). Therefore—

$$PSWR = \frac{P_{max}}{P_{min}}$$

3-151. This ratio is useful because the instruments used to detect standing waves react to the square of the voltage. Because power is proportional to the square of the voltage, the ratio of the square of the maximum and minimum voltages is called the PSWR. In a sense, the name is misleading because the power along a transmission line does not vary.

Current Standing-Wave Ratio

3-152. The ratio of maximum to minimum current along a transmission line is called current standing-wave ratio (ISWR). Therefore—

$$ISWR = \frac{I_{max}}{I_{min}}$$

3-153. This ratio is the same as that for voltages. It can be used where measurements are made with loops that sample the magnetic field along a line. It gives the same results as VSWR measurements.

SUMMARY

This chapter has presented information on the characteristics of transmission lines. The information that follows summarizes the important points of this chapter.

Transmission lines are devices for guiding electrical energy from one point to another.

Input impedance is the ratio of voltage to current at the input end of a transmission line.

Output impedance is the ratio of voltage to current at the output end of the line.

Two-wire open lines are parallel lines and have uses such as power lines, rural telephone lines, and telegraph lines. This type of line has high radiation losses and is subject to noise pickup.

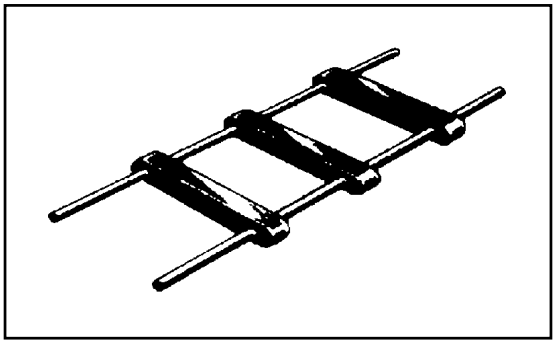

Figure 3-Sum 1. Two-Wire Open Line

The two-wire ribbon (twin lead) has parallel lines and is most often used to connect televisions to their antennas.

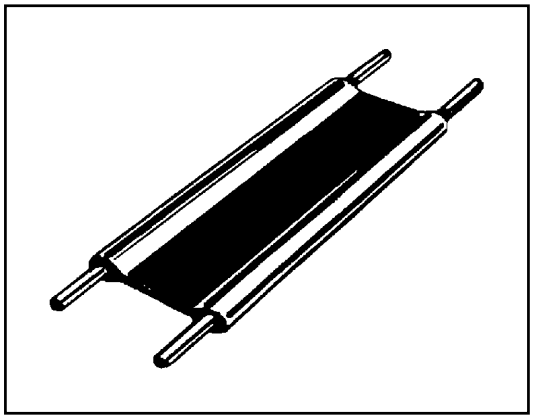

Figure 3-Sum 2. Two-Wire Ribbon Type Line

A twisted pair consists of two insulated wires twisted together. This line has high insulation loss.

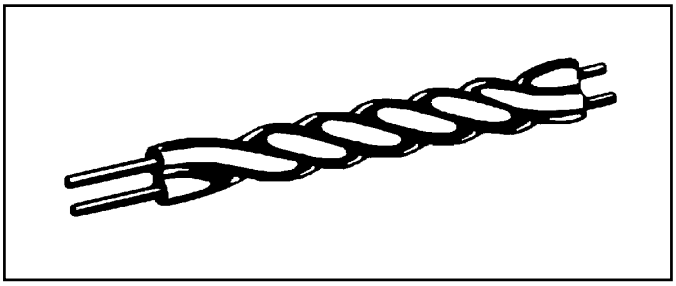

Figure 3-Sum 3. Twisted Pair

A shielded pair has parallel conductors separated by a solid dielectric and surrounded by copper braided tubing. The conductors are balanced to ground.

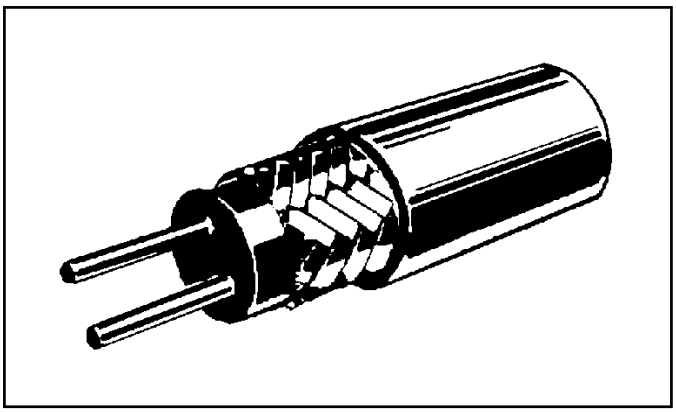

Figure 3-Sum 4. Shielded Pair

Rigid coaxial line contains two concentric conductors insulated from each other by spacers. Some rigid coaxial lines are pressurized with an inert gas to prevent moisture from entering. High-frequency losses are less than with other lines.

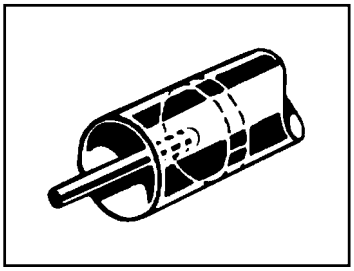

Figure 3-Sum 5. Rigid (Air) Coaxial Line

Flexible coaxial lines consist of a flexible inner conductor and a concentric outer conductor of metal braid. A continuous insulating material separates the two.

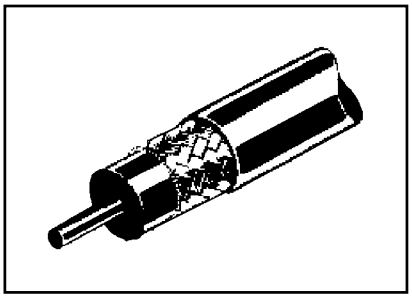

Figure 3-Sum 6. Flexible (Solid) Coaxial Lines

Waveguides are hollow metal tubes used to transfer energy from one point to another. The energy travels slower in a waveguide than in free space.

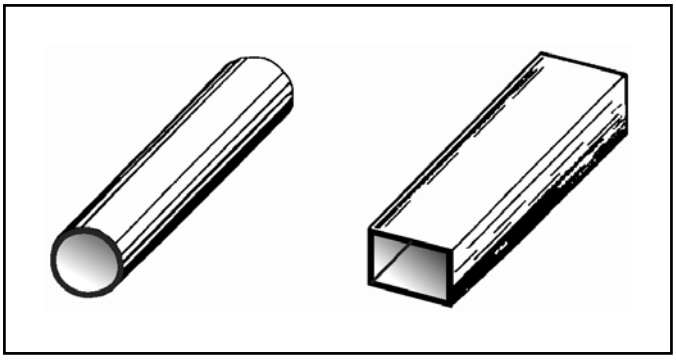

Figure 3-Sum 7. Waveguides

Copper losses can result from power (I2R) loss, in the form of heat, or skin effect. These losses decrease the conductivity of a line.

Dielectric losses are caused by the heating of the dielectric material between conductors, taking power from the source.

Radiation and induction losses are caused by part of the electromagnetic fields of a conductor being dissipated into space or nearby objects.

A transmission line is either electrically long or short if its physical length is not equal to 1/4λ for the frequency it is to carry.

Lumped constants are theoretical properties (inductance, resistance, and capacitance) of a transmission line that are lumped into a single component.

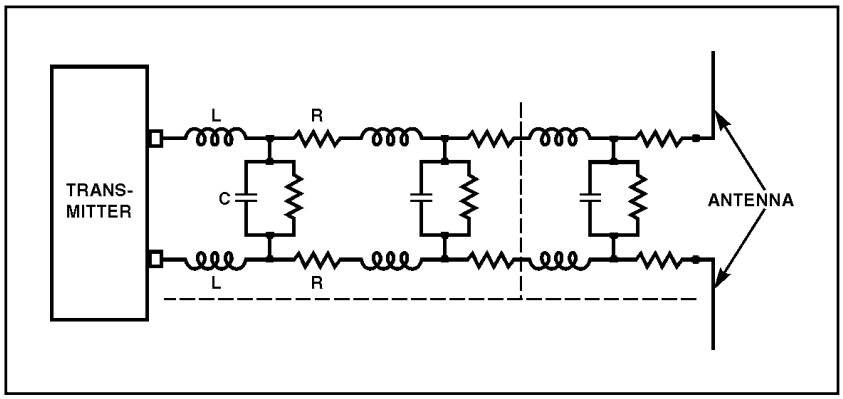

Figure 3-Sum 8. Equivalent Circuit of a Two-Wire Transmission Line

Distributed constants are constants of inductance, capacitance, and resistance that are distributed along the transmission line.

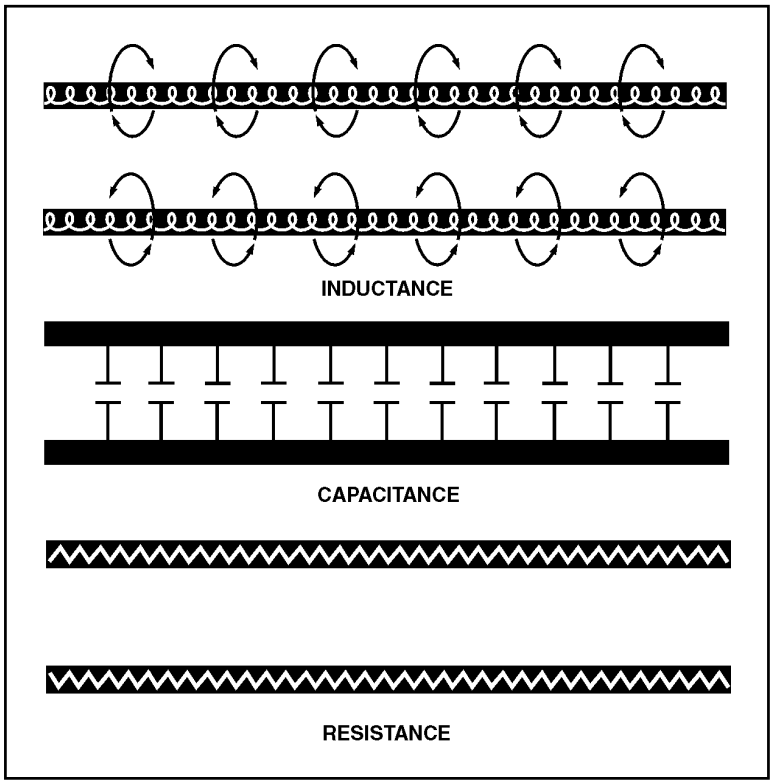

Figure 3-Sum 9. Distributed Constants

Leakage current flows between the wires of a transmission line through the dielectric. The dielectric acts as a resistor.

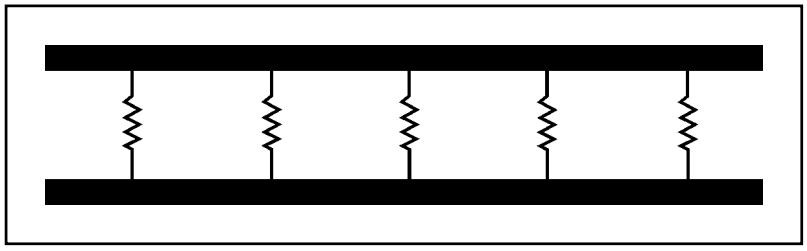

Figure 3-Sum 10. Leakage in a Transmission Line

An electromagnetic field exists along a transmission line when current flows through it.

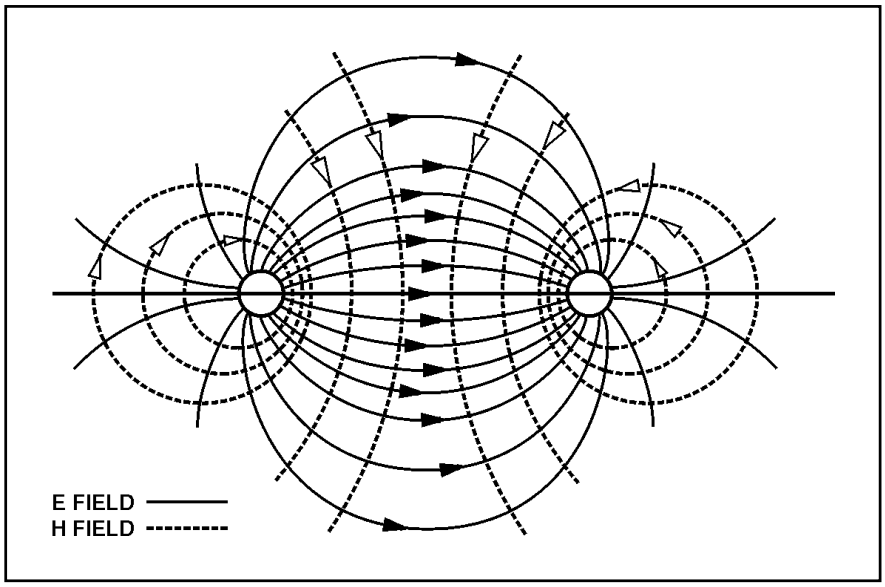

Figure 3-Sum 11. Fields between Conductors

Characteristic impedance, Z_0, is the ratio of E to I at every point along the line. For maximum transfer of electrical power, the characteristic impedance and load impedance must be matched.

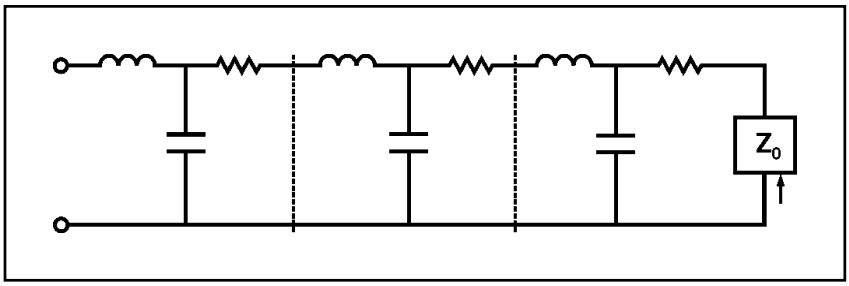

Figure 3-Sum 12. Characteristic Impedance

The velocity at which a wave travels over a given length of transmission line can be found by using the formula:

A transmission line that is not terminated in its characteristic impedance is said to be finite.

When DC is applied to an open-ended line, the voltage is reflected back from the open end without any change in polarity, amplitude, or shape. Current is reflected back with the same amplitude and shape but with opposite polarity.

When DC is applied to a short-circuited line, the current is reflected back with the same amplitude and polarity. The voltage is reflected back with the same amplitude but with opposite polarity.

When AC is applied to an open-end line, voltage is always reflected back in phase with the incident wave and current is reflected back out of phase.

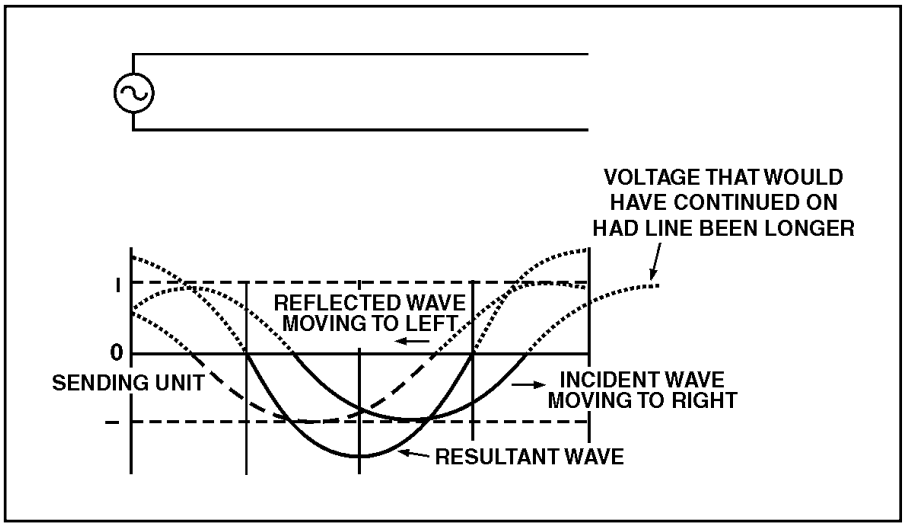

Figure 3-Sum 13. Formation of Standing Wave

When AC is applied to a short-circuited line, voltage is reflected out of phase, while current is reflected in phase.

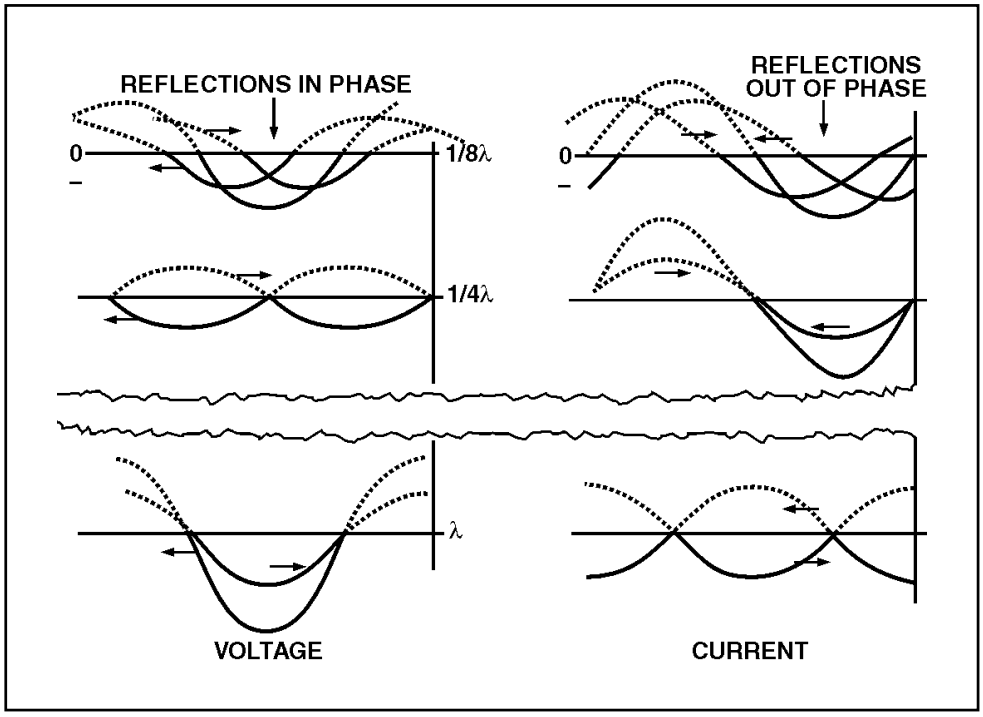

Figure 3-Sum 14. Instantaneous Values of Incident and Reflected Waves

A nonresonant line has no standing waves of current and voltage and is either infinitely long or terminated in its characteristic impedance.

A resonant line has standing waves of current and voltage and is of finite length and is not terminated in its characteristic impedance.

At all odd one-quarter wavelength points on an open-ended resonant line, the voltage is minimum, the current is maximum, and the impedance is minimum. At all even ¼λ points, the voltage is maximum, the current is minimum and the impedance is maximum.

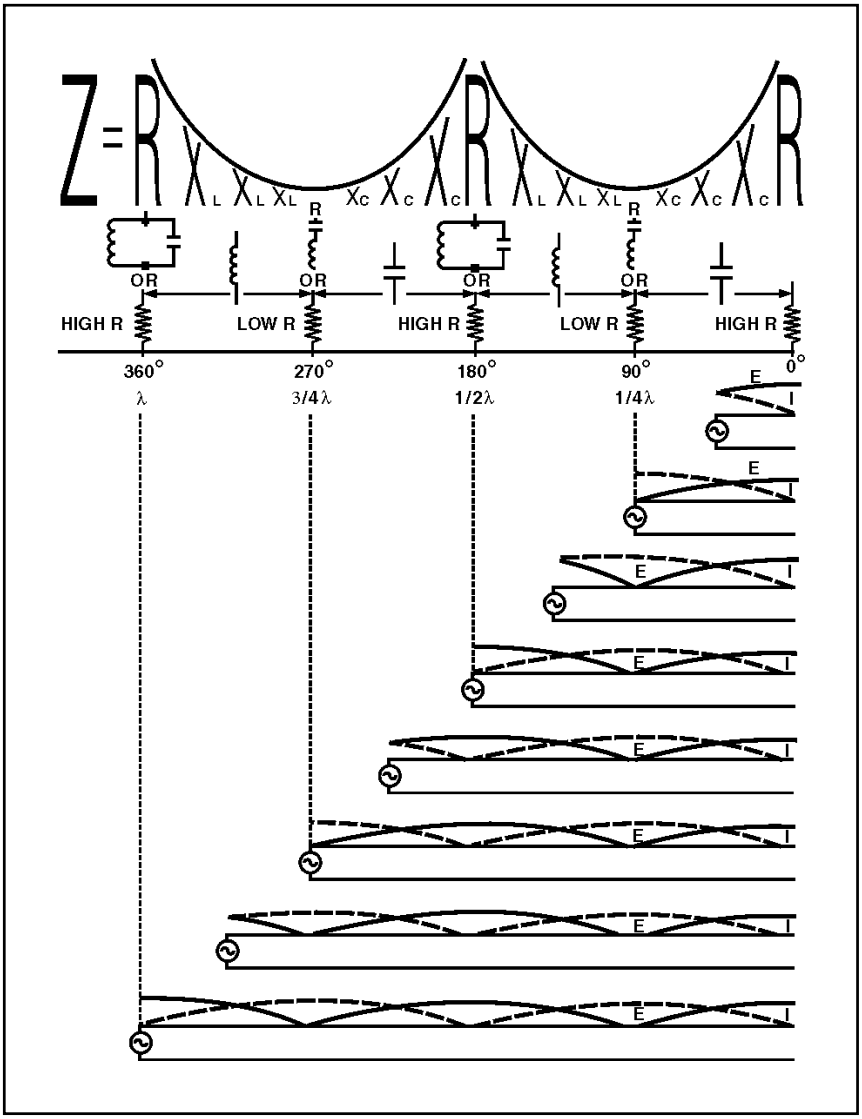

Figure 3-Sum 15. Voltage, Current, and Impedance on a Shorted Line

There are a variety of terminations for RF lines. Each termination has an effect on the standing waves on the line.

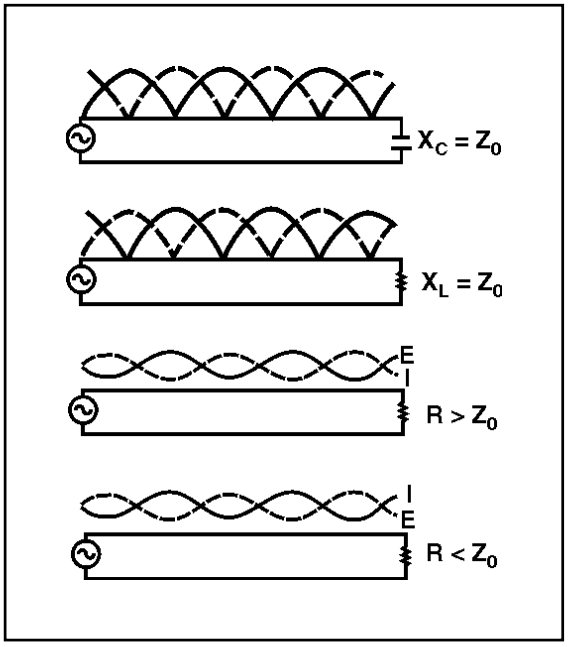

Figure 3-Sum 16. Various Termination Effects on Standing Waves

A transmission line can be terminated in its characteristic impedance as an open- or short-circuit, or in capacitance or inductance.

Whenever the termination on a transmission line is not equal to Z_0, there are reflections on the line. The amount of voltage reflected may be found by using the equation:

$$E_R = E_i\left(\frac{R_L - Z_O}{R_L + Z_O}\right)$$

When the termination on a transmission line equals Z_0, there is no reflected voltage.

The measurement of standing waves on a transmission line yields information about operating conditions. If there are no standing waves, the termination for that line is correct and maximum power transfer takes place.

The standing-wave ratio is the measurement of maximum voltage (current) to minimum voltage (current) on a transmission line and measures the perfection of the termination of the line. A ratio of 1:1 describes a line terminated in its characteristic impedance.

Check-On-Learning Questions

Principles of Transmission Lines

1. What connecting link is used to transfer energy from a radio transmitter to its antenna located on the mast of a ship?
2. What terms are used to describe the end of the transmission line that is connected to a transmitter?
3. What terms are used to describe the end of the transmission line that is connected to an antenna?
4. List the five types of transmission lines in use today.
5. Name two of the three described uses of a two-wire open line.
6. What are the two primary disadvantages of a two-wire open line?
7. What type of transmission line is often used to connect a television set to its antenna?
8. What is the primary advantage of the shielded pair?
9. What are the two types of coaxial lines in use today?
10. What is the chief advantage of the air coaxial line?
11. List the three disadvantages of the air coaxial line.
12. List the two common types of waveguides in use today.
13. What are the three types of line losses associated with transmission lines?
14. Losses caused by skin effect and the I2R (power) loss are classified as what type of loss?
15. What types of losses cause the dielectric material between the conductors to be heated?
16. What must the physical length of a transmission line be if it will be operated at 15,000,000 Hz? Use the formula:

$$\lambda = \frac{V}{f}$$

17. What are two of the three physical factors that determine the values of capacitance and inductance of a transmission line?
18. A transmission line is said to have distributed constants of inductance, capacitance, and resistance along the line. What units of measurement are used to express these constants?
19. Describe the leakage current in a transmission line and in what unit it is expressed.
20. All the power sent down a transmission line from a transmitter can be transferred to an antenna under what optimum conditions?
21. What symbol is used to designate the characteristic impedance of a line, and what two variables does it compare?
22. What is the range of the characteristic impedance of lines used in actual practice?
23. Two types of waves are formed on a transmission line. What names are given to these waves?
24. In figure 3-27, which waveforms on the left have a resultant wave of zero, and what is indicated by these waves?

25. On an open-ended transmission line, the voltage is always zero at what distance from each end of the line?
26. A nonresonant line is a line that has no standing waves of current and voltage on it and is considered to be flat. Why is this true?
27. On an open line, the voltage and impedance are maximum at what points on the line?
28. At what point on an open-circuited RF line do voltage peaks occur?
29. What is the square of the voltage standing-wave ratio called?
30. What does VSWR measure?

Chapter 4

Antennas

If you had been around in the early days of electronics, you would have considered an antenna (aerial) to be little more than a piece of wire strung between two trees or upright poles. In those days, technicians assumed that longer antennas automatically provided better reception than shorter antennas. They also believed that a mysterious medium filled all space, and that an antenna used this medium to send and receive its energy. These two assumptions have since been discarded. Modern antennas have evolved to the point that highly directional, specially designed antennas are used to relay worldwide communications in space through the use of satellites and Earth station antennas (figure 4-1). Present transmission theories are based on the assumption that space itself is the only medium necessary to propagate (transmit) radio energy.

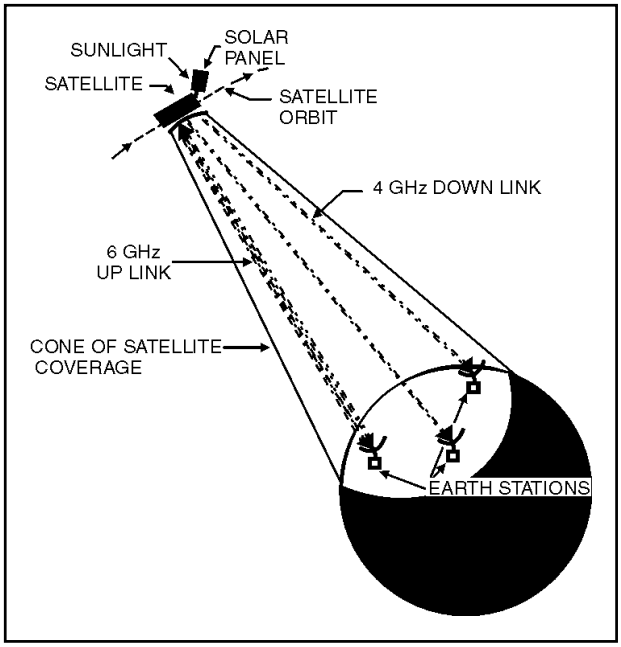

Figure 4-1. Satellite/Earth Station Communications System

4-1. A tremendous amount of knowledge and information has been gained about the design of antennas and radio wave propagation. Still, many old-time technicians will tell you that when it comes to designing the length of an antenna, the best procedure is to perform all calculations and try out the antenna. If it doesn't work right, use a cut-and-try method until it does. Fortunately, enough information has been collected over the last few decades that it is now possible to predict the behavior of antennas. This chapter discusses and explains the basic design and operation of antennas.

LEARNING OBJECTIVES

4-2. Upon completing this chapter, you should be able to do the following:

- State the basic principles of antenna radiation and list the parts of an antenna.
- Explain current and voltage distribution on an antenna.
- Describe how electromagnetic energy is radiated from an antenna.
- Explain polarization, gain, and radiation resistance characteristics of an antenna.
- Describe the theory of operation of half-wave and quarter-wave antennas.
- List the various array antennas.
- Describe the directional array antennas presented and explain the basic operation of each.
- Identify various special antennas presented, such as long-wire, V, rhombic, turnstile, ground-plane, and corner-reflector; describe the operation of each.
- List safety precautions when working aloft and around antennas.

RADIO FREQUENCY SAFETY PRECAUTIONS

4-3. Although electromagnetic radiation from transmission lines and antennas is usually of insufficient strength to electrocute personnel, it can lead to other accidents and compound injuries. Voltages may be induced in ungrounded metal objects, such as wire guys, wire cable (hawser), handrails, or ladders. If you come in contact with these objects, you could receive a shock or radio frequency (RF) burn. This shock can cause you to jump or fall into nearby mechanical equipment or, when working aloft, to fall from an elevated work area. Take care to ensure that all transmission lines or antennas are deenergized before working near or on them.

4-4. Either check or have someone check all guys, cables, rails, and ladders around your work area for RF shock dangers. Use working aloft "chits" and safety harnesses for your own safety. Signing a "working aloft chit" signifies that all equipment is in a nonradiating status. The person who signs the chit should ensure that no RF danger exists in areas where you or other personnel will be working.

4-5. Nearby ships, vans or parked aircraft are another source of RF energy that you must consider when you check a work area for safety. Combustible materials can be ignited and cause severe fires from arcs or heat generated by RF energy. Also, RF radiation can detonate ordnance devices by inducing currents in the internal wiring of the devices or in the external test equipment or leads connected to them.

4-6. Always obey RF radiation warning signs and keep a safe distance from radiating antennas. The six types of warning signs for RF radiation hazards are shown in figure 4-2.

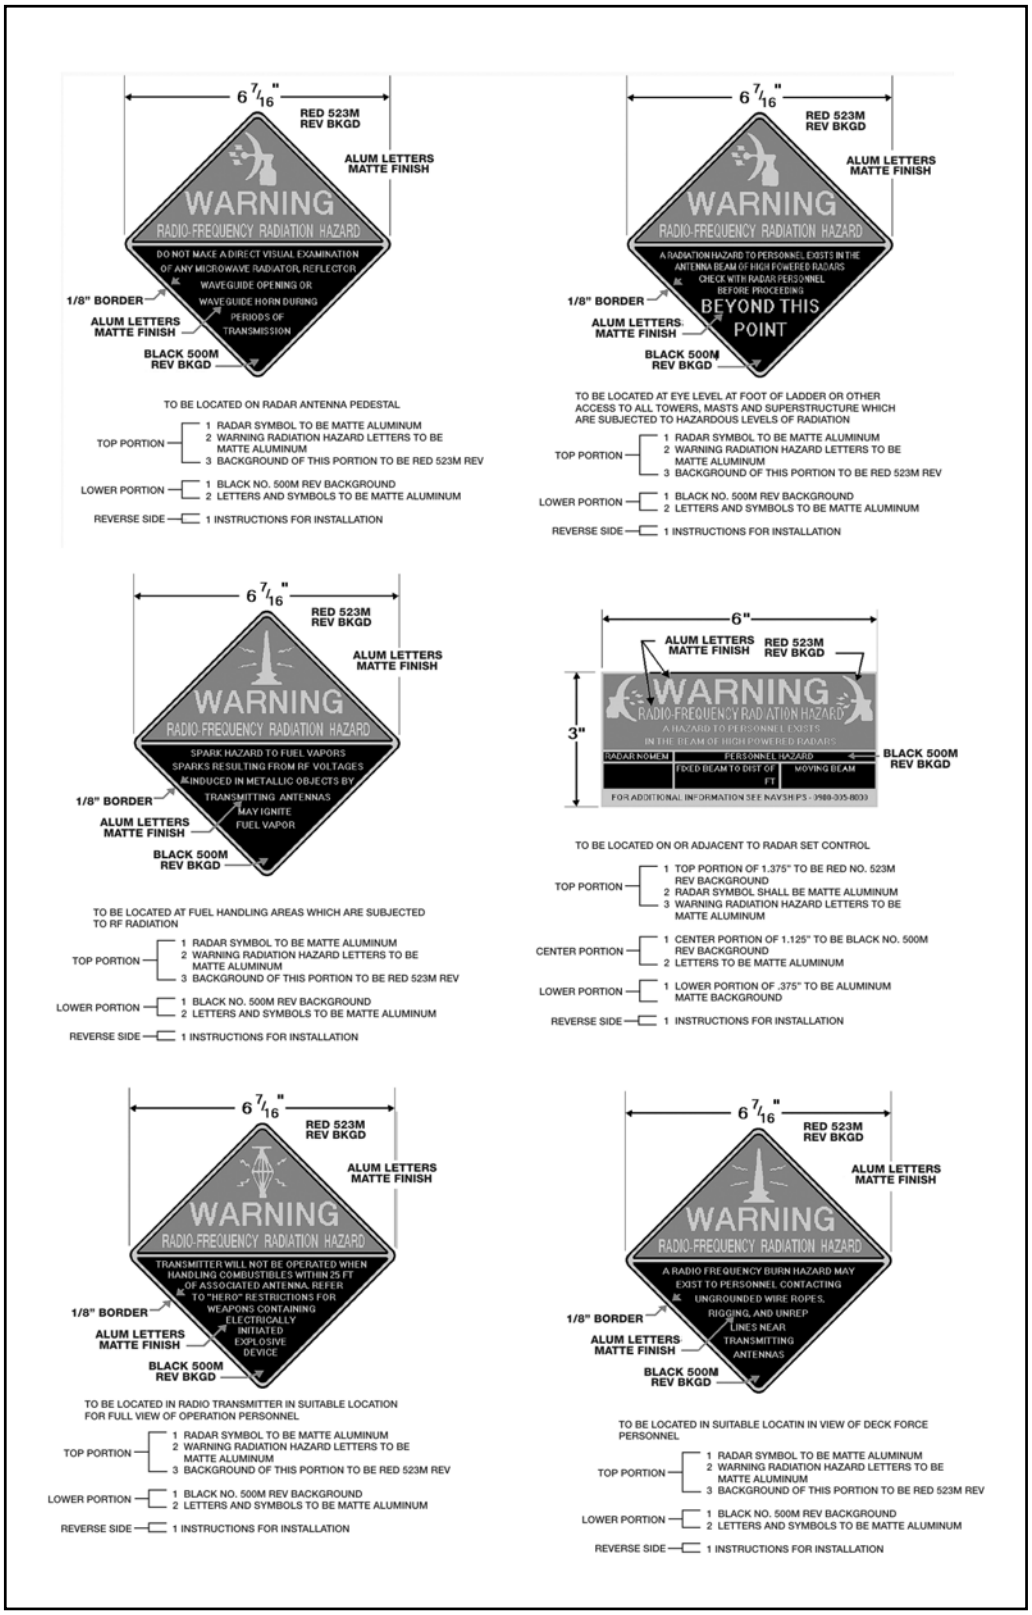

Figure 4-2. Warning Signs for Radio Frequency Radiation Hazards

RF BURNS

4-7. Close or direct contact with RF transmission lines or antennas may result in RF burns. These are usually deep, penetrating, third-degree burns. To heal properly, these burns must heal from the inside to the skin's surface. To prevent infection, you must give proper attention to all RF burns, including the small "pinhole" burns. Petrolatum gauze can be used to cover these burns temporarily, before the injured person reports to medical facilities for further treatment.

DIELECTRIC HEATING

4-8. Dielectric heating is the heating of an insulating material by placing it in a high-frequency electric field. The heat results from internal losses during the rapid reversal of polarization of molecules in the dielectric material.

4-9. In the case of a human in an RF field, the body acts as a dielectric. If the power in the RF field exceeds 10 milliwatts per centimeter, a person in that field will have a noticeable rise in body temperature. The eyes are highly susceptible to dielectric heating. For this reason, you should not look directly into devices radiating RF energy. The vital organs of the body also are susceptible to dielectric heating. For your own safety, you must not stand directly in the path of RF radiating devices.

PRECAUTIONS WHEN WORKING ALOFT

4-10. When radio or radar antennas are energized by transmitters, you must not go aloft unless advance tests show that little or no danger exists. A casualty can occur from even a small spark drawn from a charged piece of metal or rigging. Although the spark itself may be harmless, the "surprise" may cause you to let go of the antenna involuntarily and you may fall. There is also a shock hazard if nearby antennas are energized.

4-11. Rotating antennas also might cause you to fall when you are working aloft. Motor safety switches controlling the motion of rotating antennas must be tagged and locked open before you go aloft near such antennas.

PRINCIPLES OF ANTENNA RADIATION

4-12. After an RF signal has been generated in a transmitter, some means must be used to radiate this signal through space to a receiver. The device that does this job is the antenna. The transmitter signal energy is sent into space by a transmitting antenna; the RF signal is then picked up from space by a receiving antenna.

4-13. The RF energy is transmitted into space in the form of an electromagnetic field. As the traveling electromagnetic field arrives at the receiving antenna, a voltage is induced into the antenna (a conductor). The RF voltages induced into the receiving antenna are then passed into the receiver and converted back into the transmitted RF information.

4-14. The design of the antenna system is very important in a transmitting station. The antenna must be able to radiate efficiently so the power supplied by the transmitter is not wasted. An efficient transmitting antenna must have exact dimensions. The dimensions are determined by the transmitting frequencies. The dimensions of the receiving antenna are not critical for relatively low radio frequencies. However, as the frequency of the signal

being received increases, the design and installation of the receiving antenna become more critical. An example of this is a television-receiving antenna. If you raise it a few more inches from the ground or give it a slight turn in direction, you can change a snowy blur into a clear picture.

4-15. The conventional antenna is a conductor, or system of conductors, that radiates or intercepts electromagnetic wave energy. An ideal antenna has a definite length and a uniform diameter, and is completely isolated in space. However, this ideal antenna is not realistic. Many factors make the design of an antenna for a communications system a more complex problem than you would expect. These factors include the height of the radiator above the earth, the conductivity of the earth below it, and the shape and dimensions of the antenna. All of these factors affect the radiated-field pattern of the antenna in space. Another problem in antenna design is that the radiation pattern of the antenna must be directed between certain angles in a horizontal or vertical plane, or both.

4-16. Most practical transmitting antennas are divided into two basic classifications, hertz (half-wave) antennas and Marconi (quarter-wave) antennas. Hertz antennas are generally installed some distance above the ground and are positioned to radiate either vertically or horizontally. Marconi antennas operate with one end grounded and are mounted perpendicular to the earth or to a surface acting as a ground. Hertz antennas are generally used for frequencies above 2 megahertz. Marconi antennas are used for frequencies below 2 megahertz and may be used at higher frequencies in certain applications.

4-17. A complete antenna system consists of the following three parts (figure 4-3):

- The coupling device (coupling coil).
- The feeder.
- The antenna.

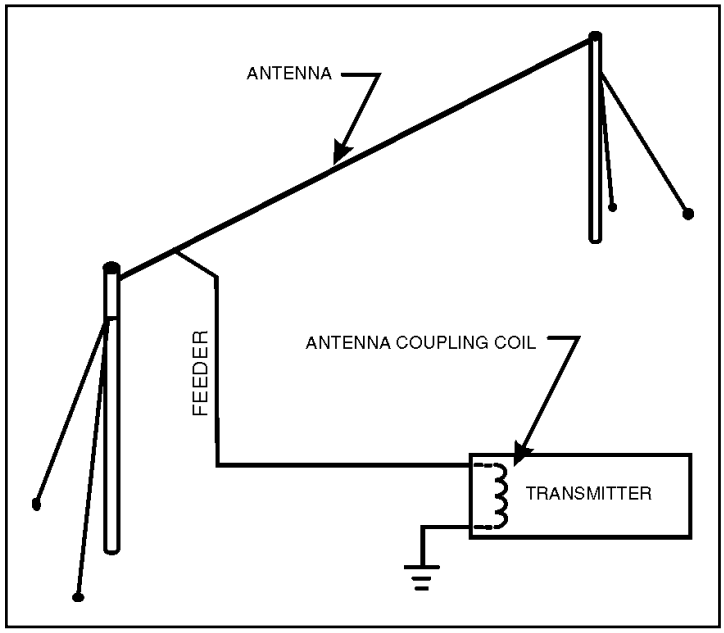

Figure 4-3. Typical Antenna System

4-18. The coupling device (coupling coil) connects the transmitter to the feeder. The feeder is a transmission line that carries energy to the antenna. The antenna radiates this energy into space.

4-19. The factors that determine the type, size, and shape of the antenna are as follows:

- The frequency of operation of the transmitter.
- Amount of power to be radiated.
- General direction of the receiving set.

Some typical antennas are illustrated in figure 4-4.

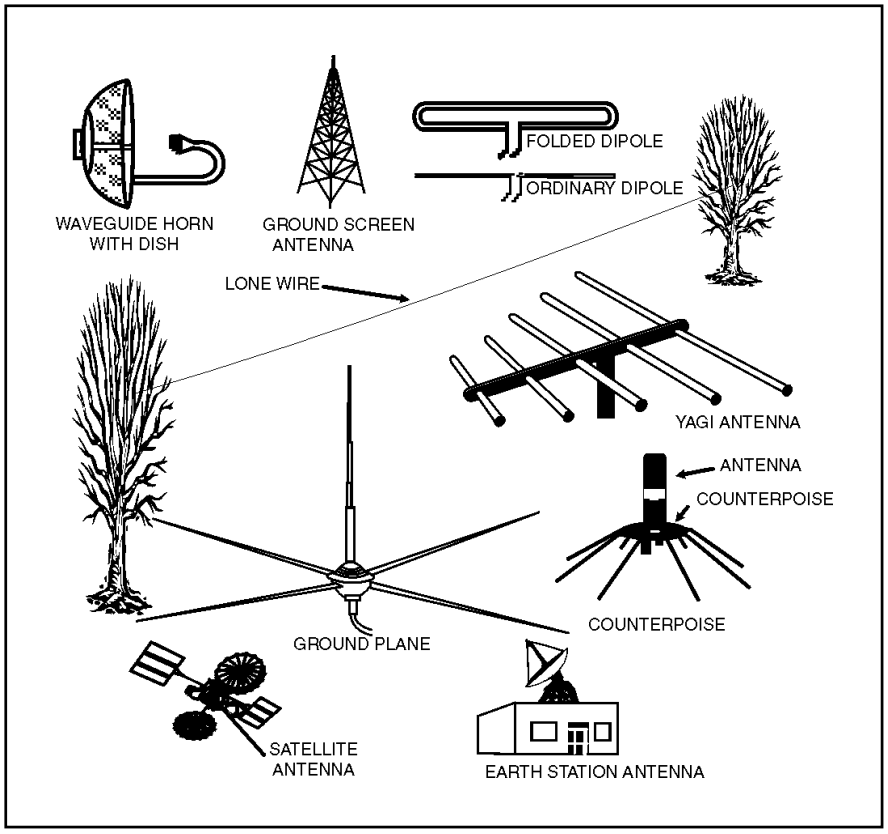

Figure 4-4. Typical Antennas

CURRENT AND VOLTAGE DISTRIBUTION ON AN ANTENNA

4-20. A current flowing in a wire whose length is properly related to the RF produces an electromagnetic field. This field is radiated from the wire and is set free in space. We discuss how these waves are set free later in this chapter. Remember, the principles of radiation of electromagnetic energy are based on two laws:

- A moving electric field creates a magnetic (H) field.
- A moving magnetic field creates an electric (E) field.

4-21. In space, these two fields are in phase and perpendicular to each other at any given time. Although a conductor is usually considered present when a moving electric or magnetic field is mentioned, the laws that govern these

fields say nothing about a conductor. Therefore, these laws hold true whether a conductor is present or not.

4-22. Figure 4-5 shows the current and voltage distribution on a half-wave (hertz) antenna. In figure 4-5, view A, a piece of wire is cut in half and attached to the terminals of a high-frequency AC generator. The frequency of the generator is set so that each half of the wire is one-quarter wavelength of the output. The result is a common type of antenna known as a dipole.

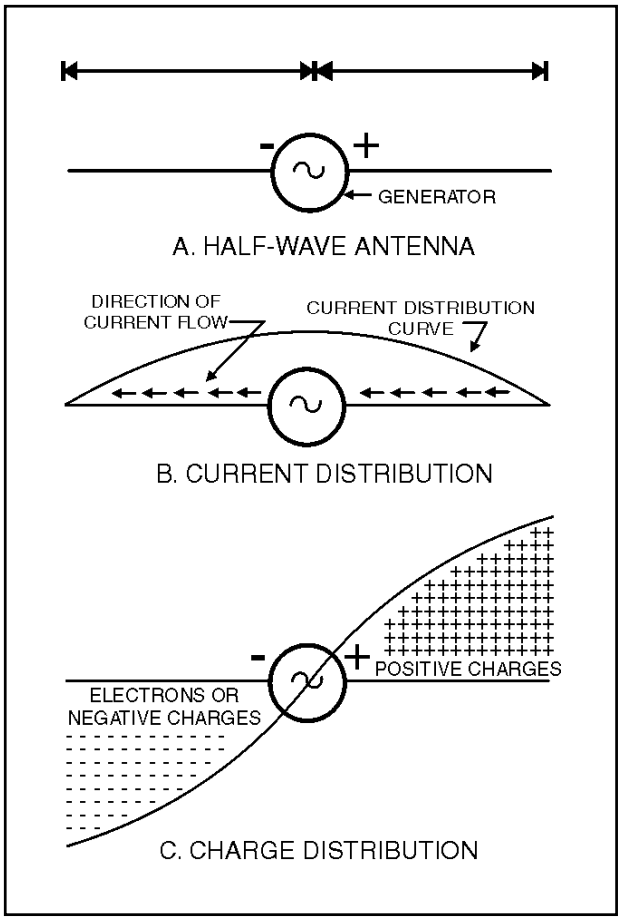

Figure 4-5. Current and Voltage Distribution on a Antenna

4-23. At a given time, the right side of the generator is positive and the left side negative. Remember that like charges repel. Because of this, electrons will flow away from the negative terminal as far as possible, but will be attracted to the positive terminal. Figure 4-5, view B shows the direction and distribution of electron flow. The distribution curve shows that most current flows in the center and none flows at the ends. The current distribution over the antenna will always be the same no matter how much or how little current is flowing. However, current at any given point on the antenna will vary directly with the amount of voltage developed by the generator.

4-24. One-quarter cycle after electrons have begun to flow, the generator will develop its maximum voltage and the current will decrease to 0. At that time the condition shown in figure 4-5 view C will exist. No current will be flowing,

but a maximum number of electrons will be at the left end of the line and a minimum number at the right end. The charge distribution along the wire will vary as the voltage of the generator varies. Therefore, you may draw the following conclusions:

- A current flows in the antenna with an amplitude that varies with the generator voltage.
- A sinusoidal distribution of charge exists on the antenna. Every one-half cycle, the charges reverse polarity.
- The sinusoidal variation in charge magnitude lags the sinusoidal variation in current by one-quarter cycle.

RADIATION OF ELECTROMAGNETIC ENERGY

4-25. The electromagnetic radiation from an antenna is made up of two components: the E field and the H field. These fields are discussed in chapters 1 and 2. The two fields occur 90 degrees out of phase with each other. These fields combine and produce a single electromagnetic field. The total energy in the radiated wave remains constant in space except for some absorption of energy by the earth. However, as the wave advances, the energy spreads out over a greater area and, at any given point, decreases as the distance increases.

4-26. Various factors in the antenna circuit affect the radiation of these waves. In figure 4-6, for example, if an alternating current is applied at the A end of the length of wire that stretches from A to B, the wave will travel along the wire until it reaches the B end. Because the B end is free, an open circuit exists and the wave cannot travel farther. This is a point of high impedance. The wave bounces back (reflects) from this point of high impedance and travels toward the starting point, where it is again reflected. Through this back-and-forth motion (oscillation), the resistance of the wire would gradually dissipate the energy of the wave; however, each time the wave reaches the starting point, it is reinforced by an amount sufficient to replace the energy lost. This results in continuous oscillations of energy along the wire and a high voltage at the A end of the wire. These oscillations are applied to the antenna at a rate equal to the frequency of the RF voltage.

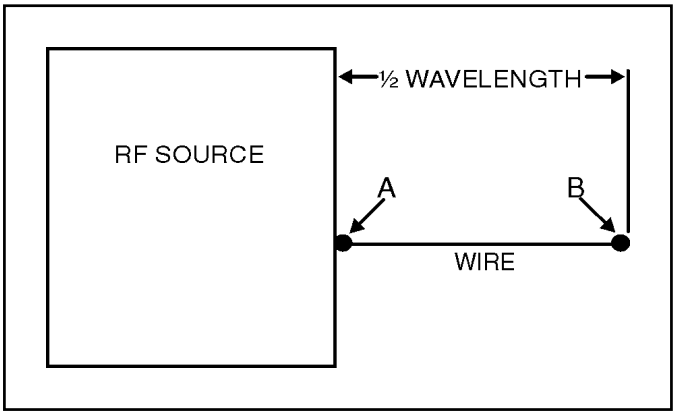

Figure 4-6. Antenna and RF Source

4-27. These impulses must be properly timed to sustain oscillations in the antenna. The rate at which the waves travel along the wire is constant at approximately 300,000,000 meters per second. The length of the antenna must be such that a wave will travel from one end to the other and back again during the period of 1 cycle of the RF voltage. Remember, the distance a wave travels during the period of 1 cycle is known as the wavelength and is found by dividing the rate of travel by the frequency.

4-28. Look at the current and voltage (charge) distribution on the antenna in figure 4-7. A maximum movement of electrons is in the center of the antenna at all times; therefore, the center of the antenna is at low impedance. This condition is called a standing wave of current. The points of high current and high voltage are known as current and voltage loops. The points of minimum current and minimum voltage are known as current and voltage nodes.

4-29. Figure 4-7, view A shows a current loop and current nodes. View B shows voltage loops and a voltage node. View C shows the resultant voltage and current loops and nodes. The presence of standing waves describes the condition of resonance in an antenna. At resonance, the waves travel back and forth in the antenna reinforcing each other and the electromagnetic waves are transmitted into space at maximum radiation. When the antenna is not at resonance, the waves tend to cancel each other and lose energy in the form of heat.

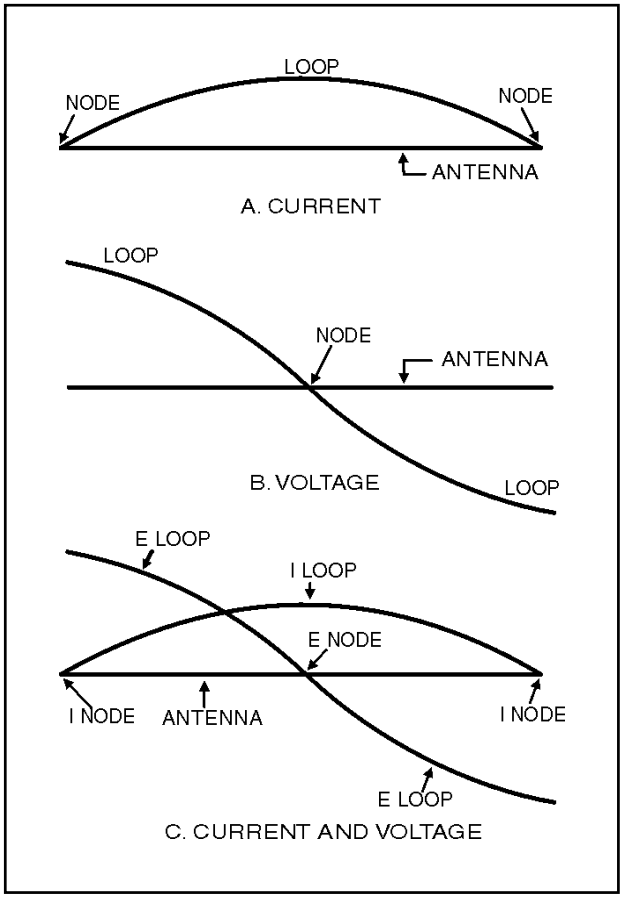

Figure 4-7. Standing Waves of Voltage and Current on an Antenna

ANTENNA CHARACTERISTICS

4-30. You can define an antenna as a conductor or group of conductors used either for radiating electromagnetic energy into space or for collecting it from space. Electrical energy from the transmitter is converted into electromagnetic energy by the antenna and radiated into space. On the receiving end, electromagnetic energy is converted into electrical energy by the antenna and is fed into the receiver.

4-31. Fortunately, separate antennas seldom are required for both transmitting and receiving RF energy. Any antenna can transfer energy from space to its input receiver with the same efficiency that it transfers energy from the transmitter into space. Of course, this is assuming that the same frequency is used in both cases. This property of interchangeability of the same antenna for transmitting and receiving is known as antenna reciprocity. Antenna reciprocity is possible because antenna characteristics are essentially the same for sending and receiving electromagnetic energy.

RECIPROCITY OF ANTENNAS

4-32. In general, the various properties of an antenna apply equally, regardless of whether you use the antenna for transmitting or receiving. The more efficient a certain antenna is for transmitting, the more efficient it will be for receiving on the same frequency. Likewise, the directive properties of a given antenna also will be the same whether it is used for transmitting or receiving.

4-33. Assume, for example, that a certain antenna used with a transmitter radiates a maximum amount of energy at right angles to the axis of the antenna, as shown in figure 4-8, view A. Note the minimum amount of radiation along the axis of the antenna. Now, if this same antenna were used as a receiving antenna, as shown in view B, it would receive best in the same directions in which it produced maximum radiation; that is, at right angles to the axis of the antenna.

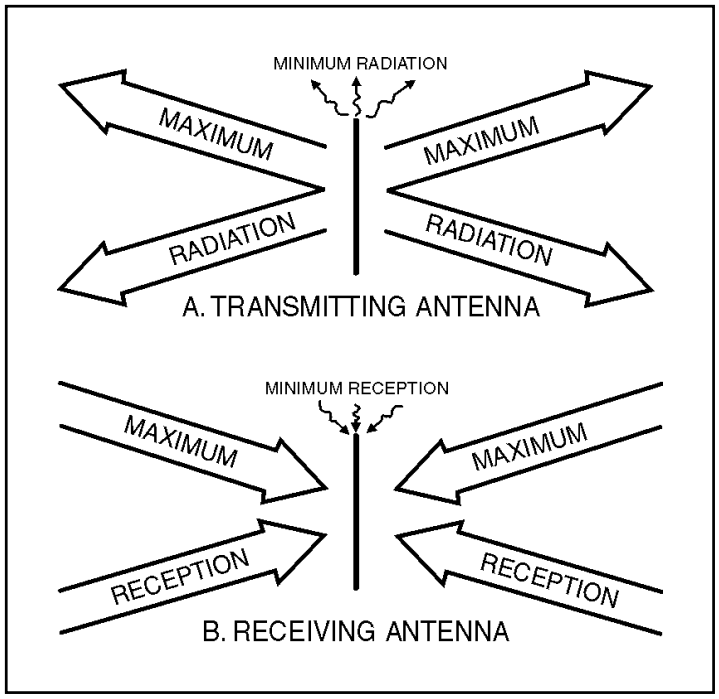

Figure 4-8. Reciprocity of Antenna

ANTENNA GAIN

4-34. Another characteristic of a given antenna that remains the same whether the antenna is used for transmitting or receiving is gain. Some antennas are highly directional; that is, more energy is propagated in certain directions than in others. The ratio between the amount of energy propagated in these directions compared to the energy that would be propagated if the antenna were not directional is known as its gain. When a transmitting antenna with a certain gain is used as a receiving antenna, it will also have the same gain for receiving.

POLARIZATION

4-35. Let us review polarization briefly. In chapter 2 you learned that the radiation field is composed of electric and magnetic lines of force. These lines of force are always at right angles to each other. Their intensities rise and fall together, reaching their maximums 90 degrees apart. The electric field determines the direction of polarization of the wave. In a vertically polarized wave, the electric lines of force lie in a vertical direction. In a horizontally polarized wave, the electric lines of force lie in a horizontal direction. Circular polarization has the electric lines of force rotating through 360 degrees with every cycle of RF energy.

4-36. The electric field was chosen as the reference field because the intensity of the wave is usually measured in terms of the electric field intensity (volts, millivolts, or microvolts per meter). When a single-wire antenna is used to extract energy from a passing radio wave, maximum pickup will result when the antenna is oriented in the same direction as the electric field. Thus, a vertical antenna is used for the efficient reception of vertically polarized

waves, and a horizontal antenna is used for the reception of horizontally polarized waves. In some cases the orientation of the electric field does not remain constant. Instead, the field rotates as the wave travels through space. Under these conditions both horizontal and vertical components of the field exist and the wave is said to have an elliptical polarization.

Polarization Requirements for Various Frequencies

4-37. Ground-wave transmission is widely used at medium and low frequencies. Horizontal polarization cannot be used at these frequencies because the electric lines of force are parallel to and touch the earth. Because the earth acts as a fairly good conductor at low frequencies, it would short out the horizontal electric lines of force and prevent the radio wave from traveling very far. Vertical electric lines of force, on the other hand are bothered very little by the earth. Therefore vertical polarization is used for ground-wave transmission, allowing the radio wave to travel a considerable distance along the ground surface with minimum attenuation.

4-38. Sky-wave transmission is used at high frequencies. Either horizontal or vertical polarization can be used with sky-wave transmission because the sky wave arrives at the receiving antenna elliptically polarized. This is the result of the wave traveling obliquely through the earth's magnetic field and striking the ionosphere. The radio wave is given a twisting motion as it strikes the ionosphere. Its orientation continues to change because of the unstable nature of the ionosphere. The relative amplitudes and phase differences between the horizontal and vertical components of the received wave also change. Therefore, the transmitting and receiving antennas can be mounted either horizontally or vertically.

4-39. Although either horizontally or vertically polarized antennas can be used for high frequencies, horizontally polarized antennas have certain advantages and are therefore preferred. One advantage is that vertically polarized interference signals, such as those produced by automobile ignition systems and electrical appliances, are minimized by horizontal polarization. Also, less absorption of radiated energy by buildings or wiring occurs when these antennas are used. Another advantage is that support structures for these antennas are of more convenient size than those for vertically polarized antennas.

4-40. For frequencies in the VHF or UHF range, either horizontal or vertical polarization is satisfactory. These radio waves travel directly from the transmitting antenna to the receiving antenna without entering the ionosphere. The original polarization produced at the transmitting antenna is maintained throughout the entire travel of the wave to the receiver. Therefore, if a horizontally polarized antenna is used for transmitting, a horizontally polarized antenna must be used for receiving. The requirements would be the same for a vertical transmitting and receiving antenna system.

4-41. For satellite communications, parallel frequencies can be used without interference by using polarized radiation. The system setup is shown in figure 4-9. One pair of satellite antennas is vertically polarized and another pair is horizontally polarized. Either vertically or horizontally polarized transmissions are received by the respective antenna and retransmitted in the same polarization. For example, transmissions may be made in the 3.7 to 3.74 GHz range on the vertical polarization path and in the 3.72 to 3.76 GHz

range on the horizontal polarization path without adjacent frequency (co-channel) interference.

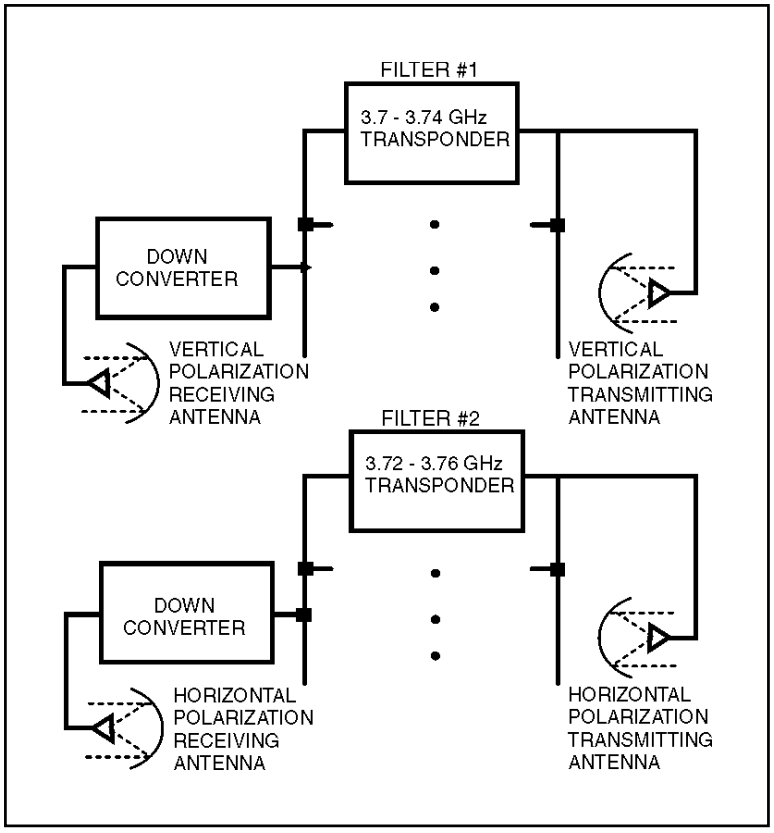

Figure 4-9. Satellite Transmissions Using Polarized Radiation

Advantages of Vertical Polarization

4-42. Simple vertical antennas can be used to provide omnidirectional (all directions) communication. This is an advantage when communications must take place from a moving vehicle.

4-43. In some overland communications, such as in vehicular installations, antenna heights are limited to 3 meters (10 feet) or less. In such instances vertical polarization results in a stronger receiver signal than does horizontal polarization at frequencies up to about 50 megahertz. From approximately 50 to 100 megahertz, vertical polarization results in a slightly stronger signal than does horizontal polarization with antennas at the same height. Above 100 megahertz, the difference in signal strength is negligible.

4-44. For transmission over bodies of water, vertical polarization is much better than horizontal polarization for antennas at the lower heights. As the frequency increases, the minimum antenna height decreases. At 30 megahertz, vertical polarization is better for antenna heights below about 91 meters (300 feet); at 85 megahertz, antenna heights below 15 meters (50 feet); and still lower heights at the high frequencies. Therefore, at ordinary antenna mast heights of 12 meters (40 feet), vertical polarization is advantageous for frequencies less than about 100 megahertz.

4-45. Radiation is somewhat less affected by reflections from aircraft flying over the transmission path when vertical polarization is used instead of horizontal polarization. With horizontal polarization, such reflections cause variations in received signal strength. This factor is important in locations where aircraft traffic is heavy.

4-46. When vertical polarization is used, less interference is produced or picked up because of strong VHF and UHF broadcast transmissions (television and FM). This is because VHF and UHF transmissions use horizontal polarization. This factor is important when an antenna must be located in an urban area having several television and FM broadcast stations.

Advantages of Horizontal Polarization

4-47. A simple horizontal antenna is bidirectional. This characteristic is useful when you wish to minimize interference from certain directions. Horizontal antennas are less likely to pick up man-made interference, which ordinarily is vertically polarized.

4-48. When antennas are located near dense forests or among buildings, horizontally polarized waves suffer lower losses than vertically polarized waves, especially above 100 megahertz. Small changes in antenna locations do not cause large variations in the field intensity of horizontally polarized waves. When vertical polarization is used, a change of only a few meters in the antenna location may have a considerable effect on the received signal strength. This is the result of interference patterns that produce standing waves in space when spurious reflections from trees or buildings occur.

4-49. When simple antennas are used, a horizontally-mounted antenna less affects the transmission line, which is usually vertical. When the antenna is mounted at right angles to the transmission line and horizontal polarization is used, the line is kept out of the direct field of the antenna. As a result, the radiation pattern and electrical characteristics of the antenna are practically unaffected by the presence of the vertical transmission line.

RADIATION RESISTANCE

4-50. Radiated energy is the useful part of the transmitter's signal. However, it represents as much of a loss to the antenna as the energy lost in heating the antenna wire. In either case, the dissipated power is equal to I^2R. In the case of heat losses, the R is real resistance. In the case of radiation, R is an assumed resistance; if this resistance were actually present, it would dissipate the same amount of power that the antenna takes to radiate the energy. This assumed resistance is referred to as the radiation resistance.

4-51. Radiation resistance varies at different points on the antenna. This resistance is always measured at a current loop. For the antenna in free space, that is, entirely removed from any objects that might affect its operation, the radiation resistance is 73 ohms. A practical antenna located over a ground plane may have any value of radiation resistance from 0 to approximately 100 ohms. The exact value of radiation resistance depends on the height of the antenna above the ground. For most half-wave wire antennas, the radiation resistance is about 65 ohms. It will usually vary between 55 and 600 ohms for antennas constructed of rod or tubing. The actual value of radiation resistance, so long as it is 50 ohms or more, has little effect on the radiation efficiency of the antenna. This is because the

ohmic resistance is about 1 ohm for conductors of large diameter. The ohmic resistance does not become important until the radiation resistance drops to a value less than 10 ohms. This may be the case when several antennas are coupled together.

RADIATION TYPES AND PATTERNS

4-52. The energy radiated from an antenna forms a field having a definite radiation pattern. A radiation pattern is a plot of the radiated energy from an antenna. This energy is measured at various angles at a constant distance from the antenna. The shape of this pattern depends on the type of antenna used. The following sections introduce the basic types of radiation (isotropic and anisotropic) and their radiation patterns.

Isotropic Radiation

4-53. Some antenna sources radiate energy equally in all directions. Radiation of this type is known as isotropic radiation. We all know the sun radiates energy in all directions. The energy radiated from the sun measured at any fixed distance and from any angle will be approximately the same. Assume that a measuring device is moved around the sun and stopped at the points indicated in figure 4-10 to make a measurement of the amount of radiation. At any point around the circle, the distance from the measuring device to the sun is the same. The measured radiation will also be the same. The sun is therefore considered an isotropic radiator.

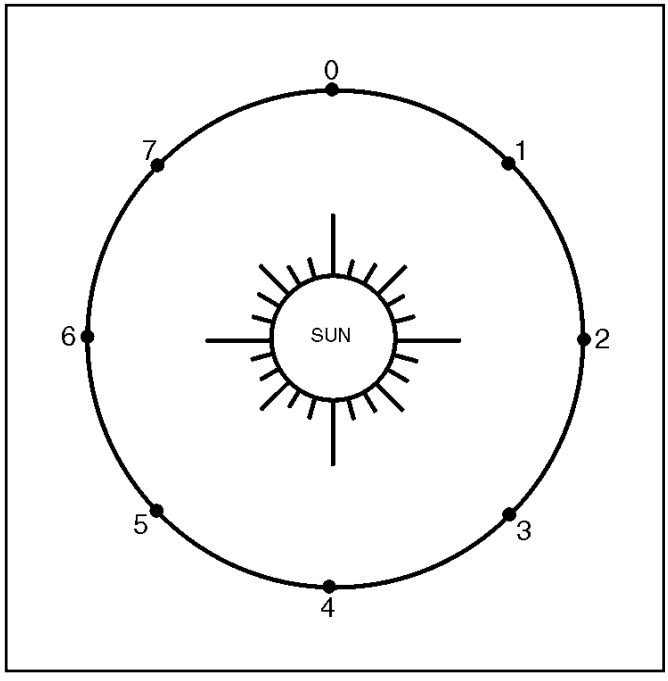

Figure 4-10. Isotropic Radiator

4-54. To plot the pattern shown in figure 4-10, assume that the radiation is measured on a scale of 0 to 10 units and that the measured amount of radiation is 7 units at all points. The measurements can be plotted on two different types of graphs: rectangular-and polar-coordinate graphs. The

rectangular-coordinate graph of the measured radiation, shown in figure 4-11, view A, is a straight line plotted against positions around the circle. View B shows the polar-coordinate graph for the same isotropic source.

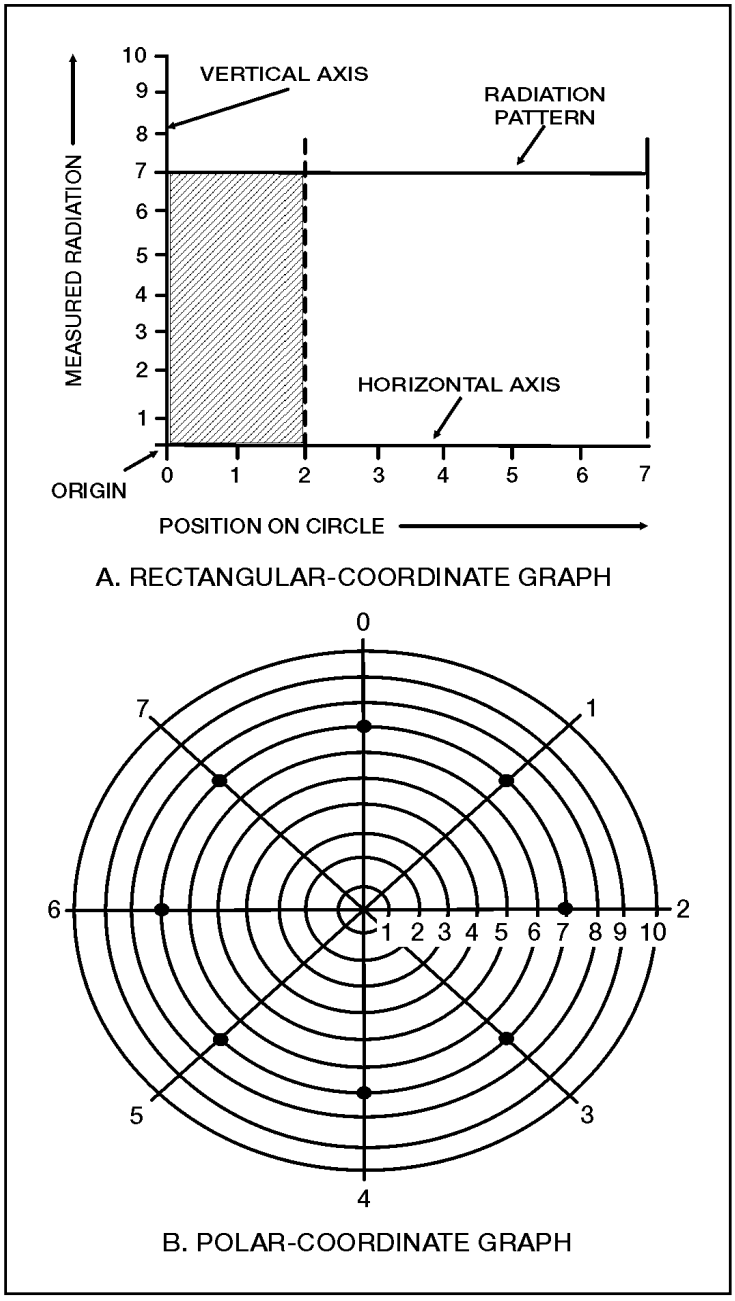

Figure 4-11. Comparison of Rectangular and Polar-Coordinate Graph for an Isotropic Source

4-55. In the rectangular-coordinate graph, points are located by projection from a pair of stationary, perpendicular axes. In the polar-coordinate graph, points are located by projection along a rotating axis (radius) to an intersection with one of several concentric, equally spaced circles. The horizontal axis on the rectangular-coordinate graph corresponds to the circles

on the polar-coordinate graph. The vertical axis on the rectangular-coordinate graph corresponds to the rotating axis (radius) on the polar-coordinate graph.

Rectangular-Coordinate Pattern

4-56. Look at figure 4-11, view A. The numbered positions around the circle are laid out on the horizontal axis of the graph from 0 to 7 units. The measured radiation is laid out on the vertical axis of the graph from 0 to 10 units. The units on both axes are chosen so the pattern occupies a convenient part of the graph.

4-57. The horizontal and vertical axes are at a right angle to each other. The point where the axes cross each other is known as the origin. In this case, the origin is 0 on both axes. Now, assume that a radiation value of 7 units is measured at position 2. From position 2 on the horizontal axis, a dotted line that runs parallel to the vertical axis is projected upwards. From position 7 on the vertical axis, a line that runs parallel to the horizontal axis is projected to the right. The point where the two lines cross (intercept) represents a value of 7 radiation units at position 2. This is the only point on the graph that can represent this value.

4-58. As you can see from the figure, the lines used to plot the point form a rectangle. For this reason, this type of plot is called a rectangular-coordinate graph. A new rectangle is formed for each different point plotted. In this example, the points plotted lie in a straight line extending from 7 units on the vertical scale to the projection of position 7 on the horizontal scale. This is the characteristic pattern in rectangular coordinates of an isotropic source of radiation.

Polar-Coordinate Pattern

4-59. The polar-coordinate graph has proved to be of great use in studying radiation patterns. Compare views A and B of figure 4-11. Note the great difference in the shape of the radiation pattern when it is transferred from the rectangular-coordinate graph in view A to the polar-coordinate graph in view B. The scale of radiation values used in both graphs is identical, and the measurements taken are both the same. However, the shape of the pattern is drastically different.

4-60. Look at figure 4-11, view B, and assume that the center of the concentric circles is the sun. Assume that a radius is drawn from the sun (center of the circle) to position 0 of the outermost circle. When you move to position 1, the radius moves to position 1; when you move to position 2, the radius also moves to position 2, and so on.

4-61. The positions where a measurement was taken are marked as 0 through 7 on the graph. Note how the position of the radius indicates the actual direction from the source at which the measurement was taken. This is a distinct advantage over the rectangular-coordinate graph in which the position is indicated along a straight-line axis and has no physical relation to the actual direction of measurement. Now that we have a way to indicate the direction of measurement, we must devise a way to indicate the magnitude of the radiation.

4-62. Notice that the rotating axis is always drawn from the center of the graph to some position on the edge of the graph (figure 4-11, view B). As the axis moves toward the edge of the graph, it passes through a set of equally

spaced, concentric circles. In this example, they are numbered successively from 1 to 10 from the center out. These circles are used to indicate the magnitude of the radiation.

4-63. The advantages of the polar-coordinate graph are immediately evident. The source, which is at the center of the observation circles, is also at the center of the graph. By looking at a polar-coordinate plot of a radiation pattern, you can immediately see the direction and strength of radiation put out by the source. Therefore, the polar-coordinate graph is more useful than the rectangular-coordinate graph in plotting radiation patterns.

Anisotropic Radiation

4-64. Most radiators emit (radiate) stronger radiation in one direction than in another. A radiator such as this is referred to as anisotropic. An example of an anisotropic radiator is an ordinary flashlight. The beam of the flashlight lights only a portion of the space surrounding it. If a circle is drawn with the flashlight as the center, as shown in figure 4-12, view B, the radiated light can be measured at different positions around the circle. Again, as with the isotropic radiator, all positions are the same distance from the center, but at different angles. However, in this illustration the radiated light is measured at 16 different positions on the circle.

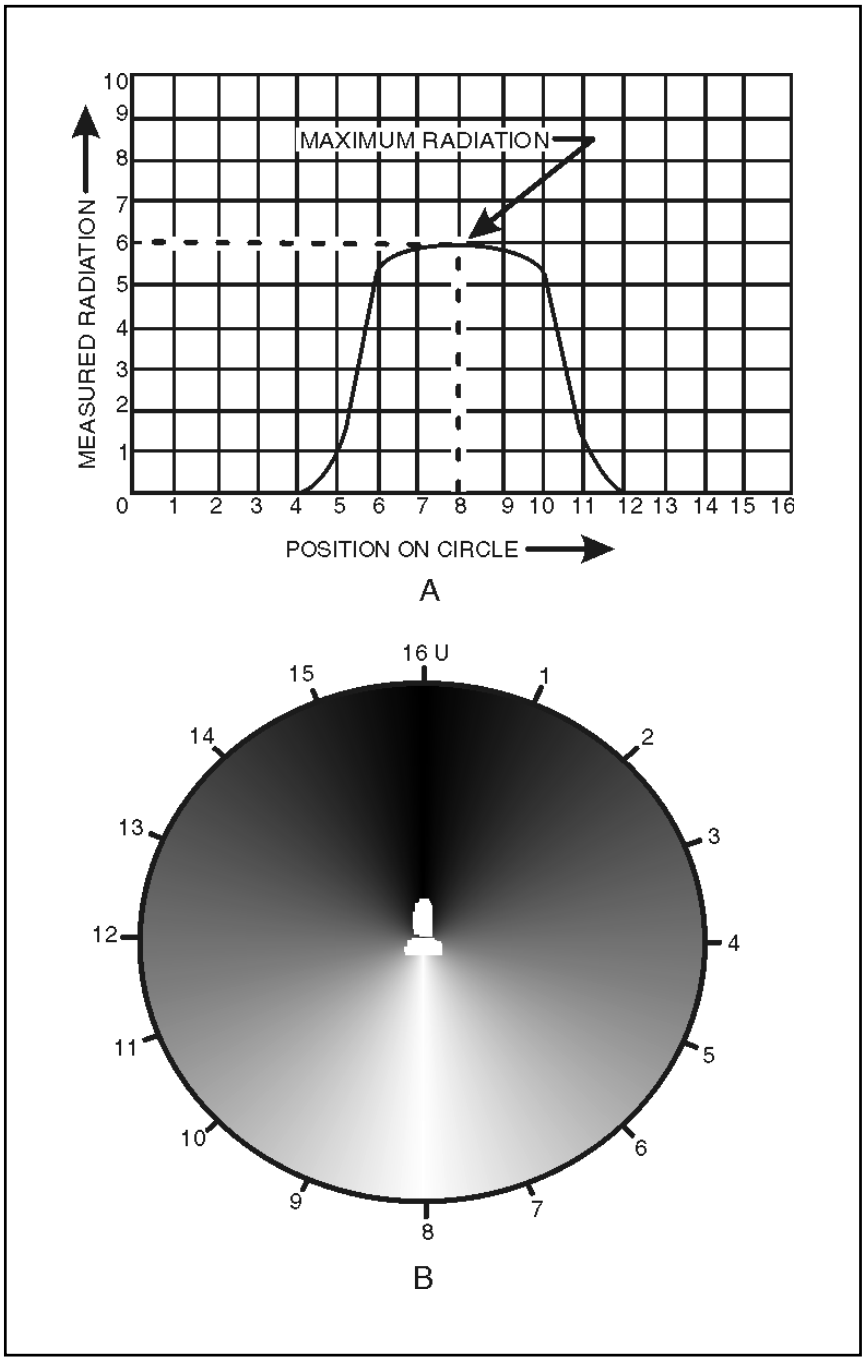

Figure 4-12. Anisotropic Radiator

4-65. Directly behind the flashlight (position 0) the radiation measured is minimum. Accordingly, a 0 value is assigned to this position in the rectangular-coordinate graph (figure. 4-12, view A). This radiation remains at minimum until position 4 is reached. Between positions 4 and 6, the measuring device enters the flashlight beam. You can see this transition from darkness to brightness easily in view B. Radiation is fairly constant between

positions 6 and 10. Maximum brightness occurs at position 8, which is directly in the path of the flashlight beam. From positions 10 to 12, the measuring device leaves the flashlight beam and the radiation measurement falls off sharply. At position 13 the radiation is again at 0 and stays at this value back to position 0.

4-66. Radiation from a light source and radiation from an antenna are both forms of electromagnetic waves. Therefore, the measurement of radiation of an antenna follows the same basic procedure as that just described for the sun and the flashlight. Before proceeding further with the study of antenna patterns, you should be sure you understand the methods used to graph the measured radiation (magnitude of the radiation). Study the rectangular and polar coordinate systems of plotting presented in the following paragraphs.

4-67. In figure 4-12, view A, the radiation pattern of the flashlight is graphed in rectangular coordinates. The illustration of the flashlight beam in figure 4-12, view B clearly indicates the shape of the flashlight beam. This shape is not evident in the radiation pattern plotted on the rectangular-coordinate graph. Now look at figure 4-13. The radiation pattern shown in this figure looks very much like the actual flashlight beam. The pattern in figure 4-13 is plotted using the same values as those of figure 4-12, view A, but is drawn using polar coordinates.

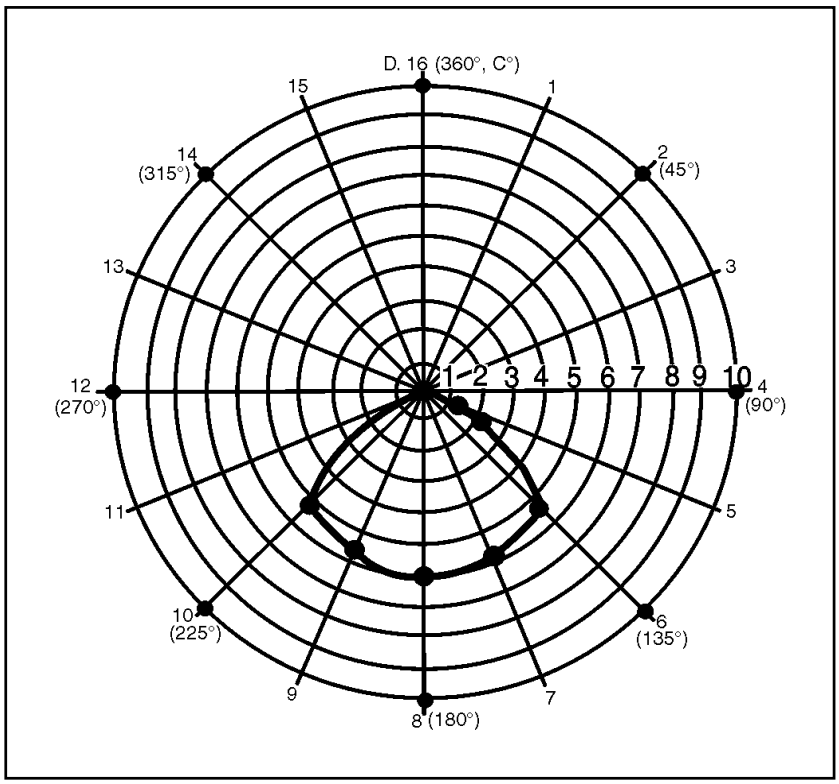

Figure 4-13. Polar-Coordinate Graph for Anisotropic Radiator

4-68. The positions marked off on the two polar-coordinate graphs in figures 4-11 and 4-13 were selected and numbered arbitrarily. However, a standard method allows the positions around a source to be marked off so that one radiation pattern can easily be compared with another. This method is based on the fact that a circle has a radius of 360 degrees. The radius extending vertically from the center (position 0 in figure 4-11) is designated 0 degrees. At position 4 the radius is at a right angle to the 0-degree radius. Accordingly, the radius at position 4 is marked 90 degrees, position 8 is 180 degrees, position 12 is 270 degrees, and position 16 is 360 degrees. The various radii drawn on the graph are all marked according to the angle each radius makes with the reference radius at 0 degrees.

4-69. The radiation pattern in figure 4-13 is obtained by using the same procedure that was used for figure 4 -10, view B. The radiation measured at positions 1, 2, 3, and 4 is 0. Position 5 measures approximately 1 unit. This is marked on the graph and the rotating radius moves to position 6. At this position a reading of 5.5 units is taken. As before, this point is marked on the graph. The procedure is repeated around the circle and a reading is obtained from positions 6 through 11. At position 12 no radiation is indicated, and this continues on to position 16.

4-70. The polar-coordinate graph now shows a definite area enclosed by the radiation pattern. This pattern indicates the general direction of radiation from the source. The enclosed area is called a lobe. Outside of this area, minimum radiation is emitted in any direction. For example, at position 2 the radiation is 0. Such a point is called a null. In real situations, some radiation is usually transmitted in all directions. Therefore, a null is used to indicate directions of minimum radiation. The pattern of figure 4-13 shows one lobe and one continuous null.

ANTENNA LOADING

4-71. You will sometimes want to use one antenna system for transmitting and receiving on several different frequencies. Because the antenna must always be in resonance with the applied frequency, you may need to lengthen or shorten the antenna physically or electrically.

4-72. Except for trailing-wire antennas used in aircraft installations (which may be lengthened or shortened), physically lengthening the antenna is not very practical. But you can achieve the same result by changing the electrical length of the antenna. To change the electrical length, you can insert either an inductor or a capacitor in series with the antenna. This is shown in figure 4-14, views A and B. Changing the electrical length by this method is known as lumped-impedance tuning, or loading. The electrical length of any antenna wire can be increased or decreased by loading. If the antenna is too short for the wavelength being used, it is resonant at a higher frequency than that at which it is being excited. Therefore, it offers a capacitive reactance at the excitation frequency. This capacitive reactance can be compensated for by introducing a lumped-inductive reactance, as shown in figure 4-14, view A. Similarly, if the antenna is too long for the transmitting frequency, it offers an inductive reactance. Inductive reactance can be compensated for by introducing a lumped-capacitive reactance, as shown in view B. An antenna without loading is represented in view C.

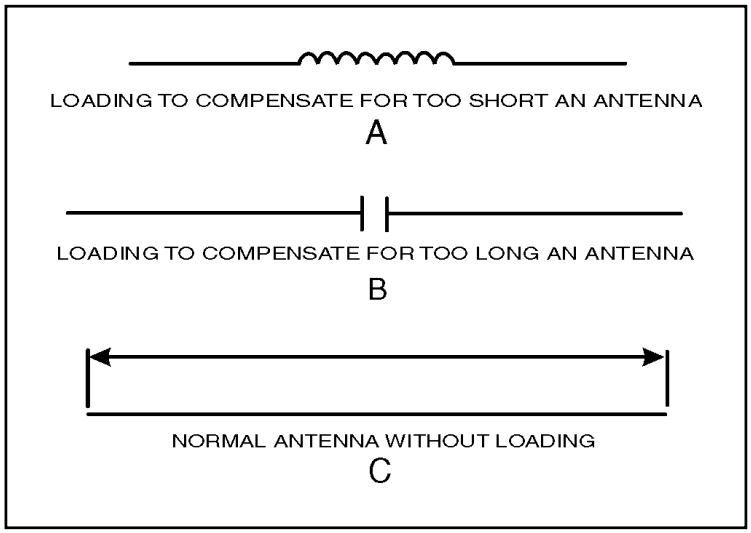

Figure 4-14. Electrically Equal Antenna

BASIC ANTENNAS

4-73. Before you look at the various types of antennas, consider the relationship between the wavelength at which the antenna is being operated and the actual length of the antenna. An antenna does not necessarily radiate or receive more energy when it is made longer. Specific dimensions must be used for efficient antenna operation.

4-74. Nearly all antennas have been developed from two basic types, the Hertz and the Marconi. The basic Hertz antenna is one-half wavelength long at the operating frequency and is insulated from ground. It is often called a dipole or a doublet. The basic Marconi antenna is one-quarter wavelength long and is either grounded at one end or connected to a network of wires called a counterpoise. The ground or counterpoise provides the equivalent of an additional one-quarter wavelength, which is required for the antenna to resonate.

HALF-WAVE ANTENNAS

4-75. A half-wave antenna (referred to as a dipole, Hertz, or doublet) consists of two lengths of wire rod, or tubing, each one-quarter wavelength long at a certain frequency. It is the basic unit from which many complex antennas are constructed. The half-wave antenna operates independently of ground; therefore, it may be installed far above the surface of the earth or other absorbing bodies. For a dipole, the current is maximum at the center and minimum at the ends. Voltage is minimum at the center and maximum at the ends, as shown in figure 4-7.

Radiation Patterns

4-76. In the following discussion, the term dipole is used to mean the basic half-wave antenna. The term doublet is used to indicate an antenna that is very short compared with the wavelength of the operating frequency. Physically, it has the same shape as the dipole.

4-77. **Radiation pattern of a doublet**. The doublet is the simplest form of a practical antenna. Its radiation pattern can be plotted in the same way as the radiation pattern of the flashlight shown in figure 4-13. Figure 4-15 illustrates the development of vertical and horizontal patterns for a doublet. This is not a picture of the radiation, but three-dimensional views of the pattern itself that the radiation makes. In three views (views B, C, and D), the pattern resembles a doughnut. From the dimensions in these views, two types of polar-coordinate patterns can be drawn: horizontal and vertical. The horizontal pattern shown in view A is derived from the solid pattern shown in view C by slicing it horizontally. This produces view B, which is converted to the polar coordinates seen in view A. The horizontal pattern illustrates that the radiation is constant in any direction along the horizontal plane.

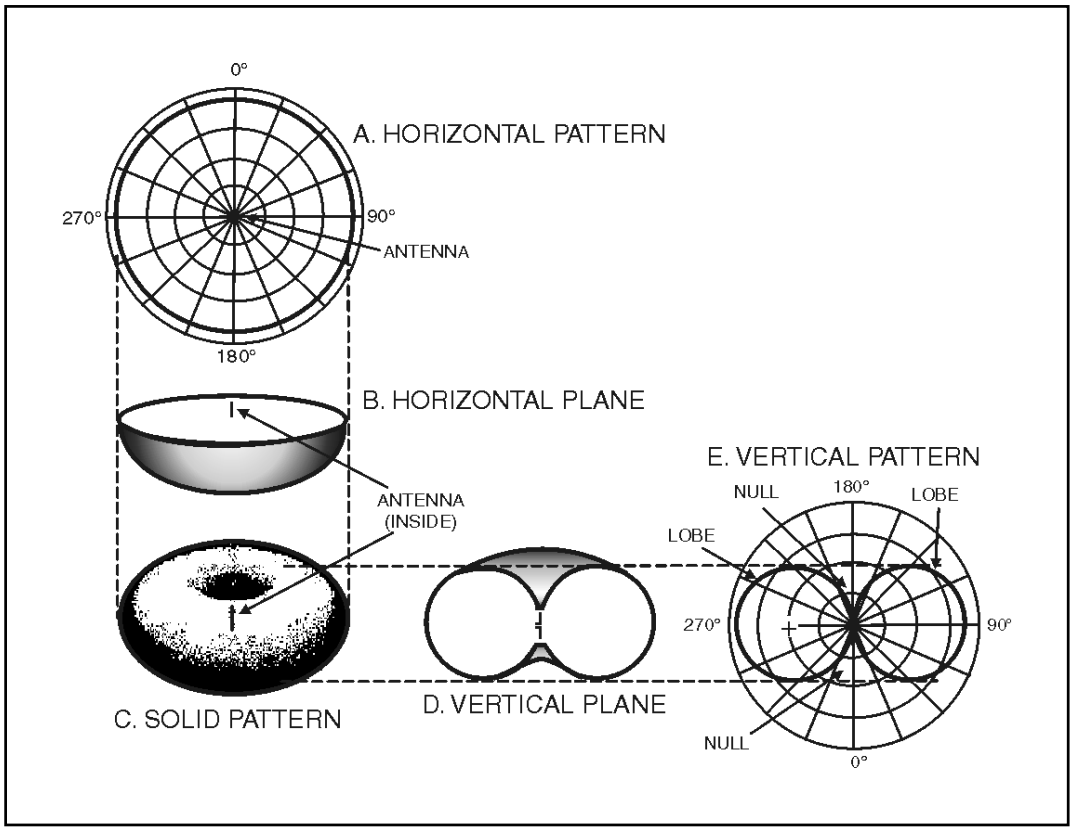

Figure 4-15. Development of Vertical and Horizontal Pattern

4-78. A vertical pattern shown in figure 4-15, view E is depicted from the drawing of the vertical plane (view D) of the radiation pattern shown in view C. The radiation pattern in view C is sliced in half along a vertical plane through the antenna. This produces the vertical plane pattern shown in view D. Note how the vertical plane in view D of the radiation pattern differs from the horizontal plane in view B. The vertical pattern in view E exhibits two lobes and two nulls. The difference between the two patterns is caused by two facts: (1) no radiation is emitted from the ends of the doublet; and (2) maximum radiation comes from the doublet in a direction perpendicular to the antenna axis. This type of radiation pattern is both nondirectional (in a horizontal plane) and directional (in a vertical plane).

4-79. From a practical viewpoint, the doublet antenna can be mounted either vertically or horizontally. The doublet shown in figure 4-15 is mounted vertically, and the radiated energy spreads out about the antenna in every direction in the horizontal plane. Because ordinarily the horizontal plane is the useful plane, this arrangement is termed nondirectional. The directional characteristics of the antenna in other planes are ignored. If the doublet were mounted horizontally, it would have the effect of turning the pattern on edge, reversing the patterns given in figure 4-15. The antenna would then be directional in the horizontal plane. The terms "directional" and "nondirectional" are used for convenience in describing specific radiation patterns. A complete description always involves a figure in three dimensions, as in the radiation pattern of figure 4-15.

4-80. **Radiation pattern of a dipole**. The radiation pattern of a dipole (figure 4-16) is similar to that of the doublet (figure 4-15). Increasing the length of the doublet to one-half wavelength has the effect of flattening out the radiation pattern. The radiation pattern in the horizontal plane of a dipole is a larger circle than that of the doublet. The vertical-radiation pattern lobes are no longer circular. They are flattened out and the radiation intensity is greater.

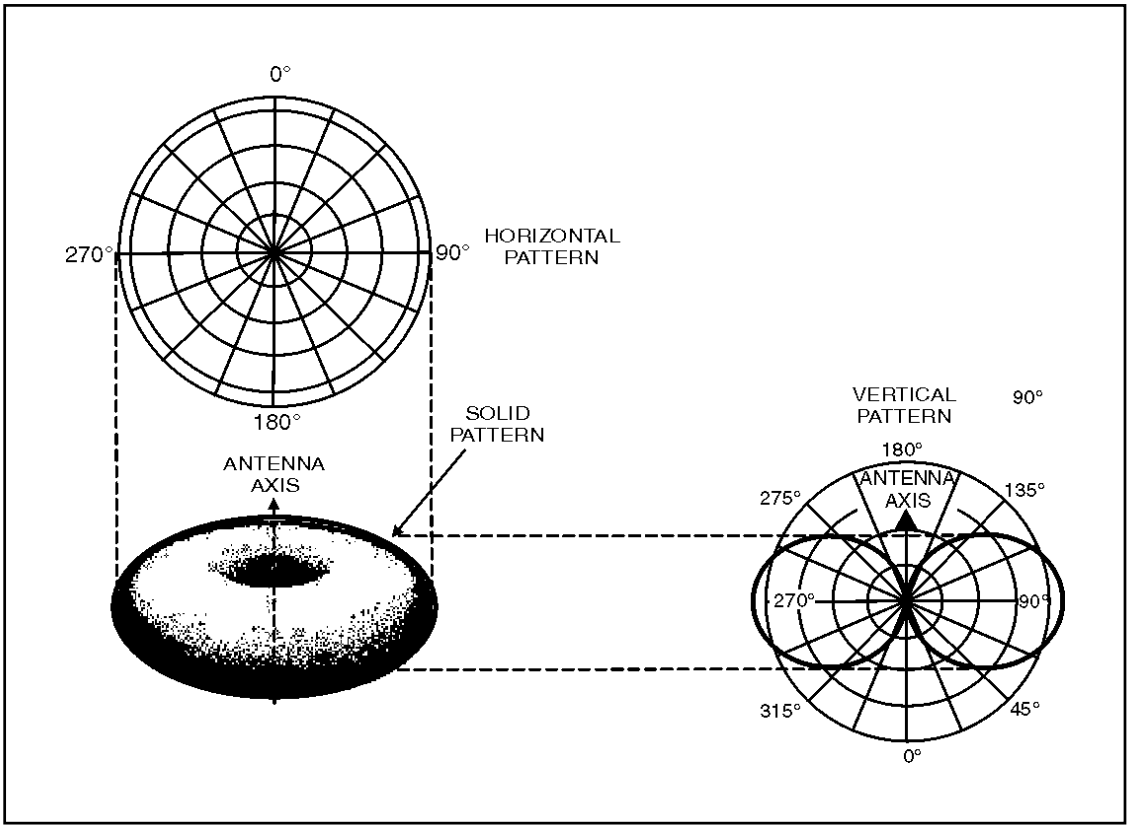

Figure 4-16. Radiation Pattern of a Dipole

Methods of Feeding Energy to an Antenna

4-81. Voltage and current distribution for the half-wave antenna (shown in figure 4-17) is the same as that for the antenna discussed earlier in this chapter. A point closely related to the voltage and current distribution on an antenna is the method of feeding the transmitter output to the antenna. The simplest method of feeding energy to the half-wave antenna is to connect one end through a capacitor to the final output stage of the transmitter. This method is often called the end-feed or voltage-feed method. In this method the antenna is fed at a point of high voltage (the end).

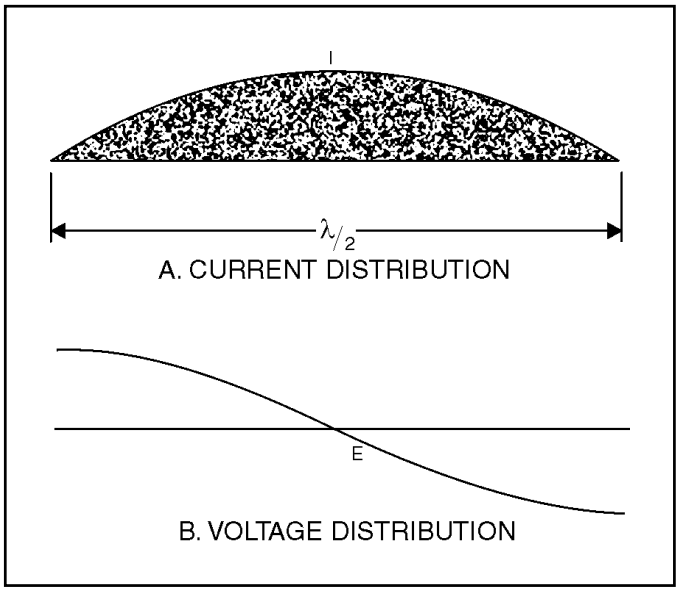

Figure 4-17. Standing Waves of Current and Voltage

4-82. Energy may also be fed to the half-wave antenna by dividing the antenna at its center and connecting the transmission line from the final transmitter output stage to the two center ends of the halved antenna. Because the antenna is now being fed at the center (a point of low voltage and high current), this type of feed is known as the center-feed or current-feed method. The point of feed is important in determining the type of transmission line to be used.

QUARTER-WAVE ANTENNAS

4-83. As you have studied in the previous sections, a one-half wavelength antenna is the shortest antenna that can be used in free space. If we cut a half-wave antenna in half and then ground one end, we will have a grounded quarter-wave or Marconi antenna. This antenna will resonate at the same frequency as the ungrounded half-wave antenna. Quarter-wave antennas are widely used in the military. Most mobile transmitting and receiving antennas (illustrated in figure 4-18) are quarter-wave antennas.

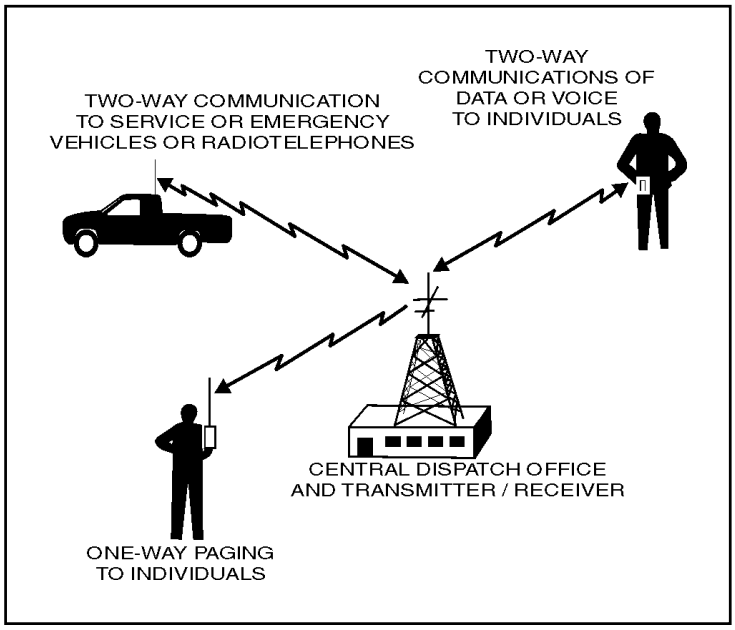

Figure 4-18. Mobile Antennas

4-84. As stated above, a grounded quarter-wave antenna will resonate at the same frequency as an ungrounded half-wave antenna. This is because the ground has high conductivity and acts as an electrical mirror image. This characteristic provides the missing half of the antenna, as shown in the bottom part of figure 4-19. In other words, the grounded quarter-wave antenna acts as if another quarter-wave were actually down in the earth.

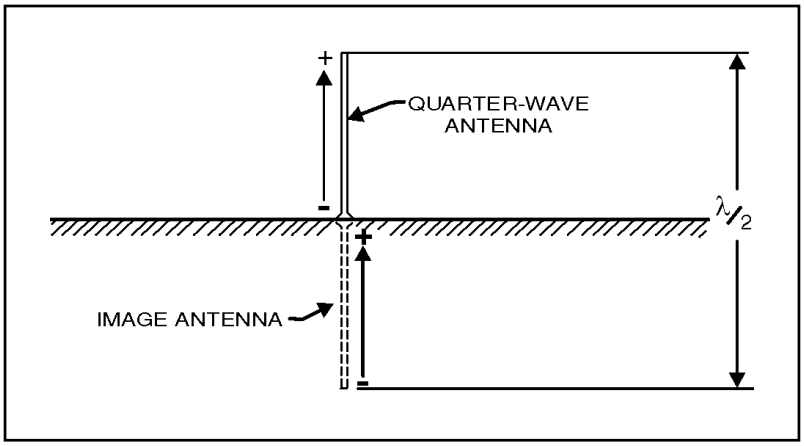

Figure 4-19. Grounded Quarter-Wave Antenna Image

Characteristics of Quarter-Wave Antennas

4-85. The grounded end of the quarter-wave antenna has a low input impedance and has low voltage and high current at the input end, as shown in figure 4-19. The ungrounded end has a high impedance, which causes high voltage and low current. The directional characteristics of a grounded quarter-wave antenna are the same as those of a half-wave antenna in free space.

4-86. As explained earlier, ground losses affect radiation patterns and cause high signal losses for some frequencies. Such losses may be greatly reduced if a perfectly conducting ground is provided in the vicinity of the antenna. This is the purpose of a ground screen (figure 4-20, view A) and counterpoise (view B).

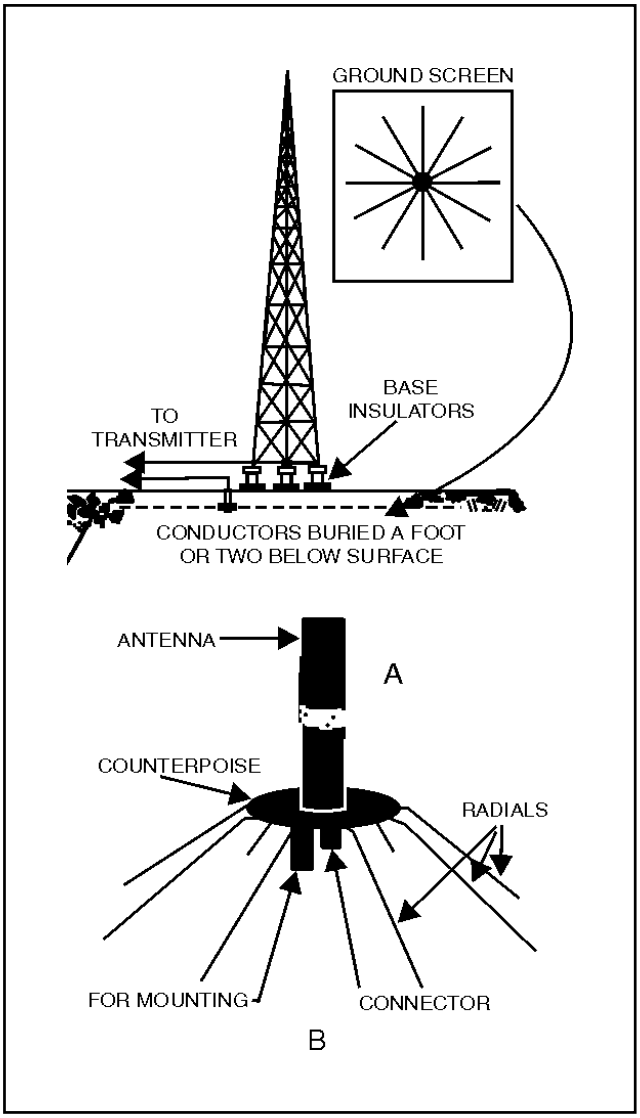

Figure 4-20. Ground Screen and Counterpoise

4-87. The ground screen in figure 4-20, view A is composed of a series of conductors buried 1 to 2 feet (0.3 to 0.6 meter) below the surface of the earth and arranged in a radial pattern. These conductors reduce losses in the ground in the immediate vicinity of the antenna. Such a radial system of conductors is usually one-half wavelength in diameter.

4-88. A counterpoise, as shown in figure 4-20, view B, is used when easy access to the base of the antenna is necessary. It is also used when the earth is not a good conducting surface, such as ground that is sandy or solid rock. The counterpoise serves the same purpose as the ground screen but it is

usually elevated above the earth. No specific dimensions are necessary in the construction of a counterpoise nor is the number of wires particularly critical. A practical counterpoise may be assembled from a large screen of chicken wire or some similar material. This screen may be placed on the ground, but better results are obtained if it is placed a few feet above the ground.

FOLDED DIPOLE

4-89. The use of parasitic elements and various stacking arrangements causes a reduction in the radiation resistance of a center-fed, half-wave antenna. Under these conditions, obtaining a proper impedance match between the radiator and the transmission line is often difficult. A convenient method of overcoming these difficulties is to use a folded dipole in place of the center-fed radiator. (See figure 4-21, views A and B).

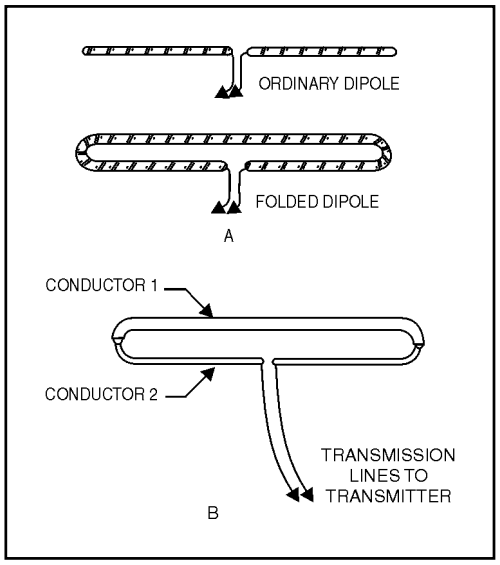

Figure 4-21. Folded-Dipole Antennas

4-90. A folded dipole is an ordinary half-wave antenna that has one or more additional conductors connected across its ends. Additional conductors are mounted parallel to the dipole elements at a distance equal to a very small fraction of a wavelength. Spacing of several inches is common.

4-91. The feed-point impedance can be further increased by using three or four properly spaced parallel conductors. Standard feed-line spreaders are used to maintain this spacing when required. In any folded dipole, the increase of impedance is the square of the number of conductors used in the radiator. Thus, a three-wire dipole has nine times (3^2) the feed-point impedance of a simple center-fed dipole. A second method of stepping up the impedance of a folded dipole is to use two conductors with different radii, as shown in figure 4-21, view B.

4-92. The directional characteristics of a folded dipole are the same as those of a simple dipole. However, the reactance of a folded dipole varies much more slowly as the frequency is varied from resonance. Because of this

difference, the folded dipole can be used over a much wider frequency range than is possible with a simple dipole.

ARRAY ANTENNAS

4-93. An array antenna is a special arrangement of basic antenna components. The discussion of array antennas includes the following new terms that you should study before moving on to the section on phasing.

DEFINITION OF TERMS

4-94. An *array antenna* is made up of more than one element, but the basic element is generally the dipole. Sometimes the basic element is made longer or shorter than a half-wave, but the deviation usually is not great.

4-95. A *driven element* is similar to the dipole you have been studying and is connected directly to the transmission line. It obtains its power directly from the transmitter or, as a receiving antenna; it delivers the received energy directly to the receiver. A parasitic element is located near the driven element from which it gets its power. It is placed close enough to the driven element to permit coupling.

4-96. A *parasitic element* is sometimes placed so it will produce maximum radiation (during transmission) from its associated driver. When it operates to reinforce energy coming from the driver toward itself, the parasitic element is referred to as a *director*. If a parasitic element is placed so it causes maximum energy radiation in a direction away from itself and toward the driven element, that parasitic element is called a reflector.

4-97. If all of the elements in an array are driven, the array is referred to as a *driven array* (sometimes as a *connected array*). If one or more elements are parasitic, the entire system usually is considered to be a *parasitic array*.

4-98. Multi-element arrays frequently are classified according to their directivity. A *bidirectional array* radiates in opposite directions along the line of maximum radiation. A *unidirectional array* radiates in only one general direction.

4-99. Arrays can be described with respect to their radiation patterns and the types of elements of which they are made. However, you will find it useful to identify them by the physical placement of the elements and the direction of radiation with respect to these elements. Generally speaking, the term *broadside array* designates an array in which the direction of maximum radiation is perpendicular to the plane containing these elements. In actual practice, this term is confined to those arrays in which the elements themselves are also broadside, or parallel, with respect to each other.

4-100. A *collinear array* is one in which all the elements lie in a straight line with no radiation at the ends of the array. The direction of maximum radiation is perpendicular to the axis of the elements.

4-101. An *end-fire array* is one in which the principal direction of radiation is along the plane of the array and perpendicular to the elements. Radiation is from the end of the array, which is the reason this arrangement is referred to as an end-fire array.

4-102. Sometimes a system uses the characteristics of more than one of the three types mentioned. For instance, some of the elements may be collinear

while others may be parallel. Such an arrangement is often referred to as a *combination array* or an *array of arrays*. Because maximum radiation occurs at right angles to the plane of the array, the term *broadside array* is also used.

4-103. The *front-to-back ratio* is the ratio of the energy radiated in the principal direction compared to the energy radiated in the opposite direction for a given antenna.

PHASING

4-104. Various reflected and refracted components of the propagated wave create effects of reinforcement and cancellation. At certain distant points from the transmitter, some of the wave components meet in space. Reception at these points is either impaired or improved. If the different components arrive at a given point in the same phase, they add, making a stronger signal available. If they arrive out of phase, they cancel, reducing the signal strength.

Radiation Pattern

4-105. Effects similar to those described in the preceding paragraph can be produced at the transmitting point itself. Consider the antennas shown in figure 4-22, views A and B. View A shows an unobstructed view of the radiation pattern of a single dipole. In view B, two dipoles, shown as points 1 and 2, are perpendicular to the plane of the page. They are spaced one-quarter wavelength apart at the operating frequency. The radiation pattern from either antenna 1 or 2, operating alone, would be uniform in all directions in this plane, as shown in view A. Suppose that current is being fed to both antennas from the same transmitter in such a way that the current fed to antenna 2 lags the current in antenna 1 by 90 degrees. Energy radiating from antenna 1 toward receiving location X will reach antenna 2 after one-quarter cycle of operation. The energy from both antennas will add, and propagation toward X will be strong.

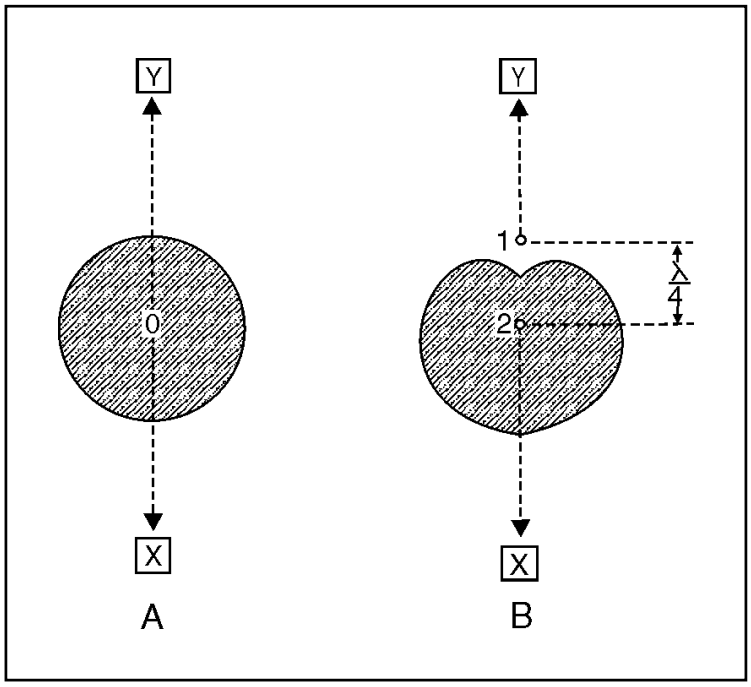

Figure 4-22. Phasing of Antenna in Free Space

4-106. Radiation from antenna 2 toward receiving location Y will reach antenna 1 after one-quarter cycle. The energy in antenna 1 was one-quarter cycle behind that of antenna 2 to begin with; therefore, the radiation from antenna 1 toward receiving point Y will be exactly 180 degrees out of phase with that of antenna 2. As a result, the radiation fields will cancel and there will be no radiation toward Y.

4-107. At receiving points away from the line of radiation, phase differences occur between 0 and 180 degrees, producing varying amounts of energy in that direction. The overall effect can be seen in the radiation pattern illustrated in view B. The physical phase relationship caused by the wavelength spacing between the two elements, as well as the phase of the currents in the elements, has acted to change the radiation pattern of the individual antennas.

Stub Phasing

4-108. In the case just discussed, the currents fed to the two antennas from the same transmitter were 90 degrees out of phase. Sections of transmission line, called stubs, are frequently used for this purpose. These stubs can be adjusted to produce any desired phase relationship between connected elements.

4-109. When two collinear half-wave elements are connected directly so their currents are in the same phase, the effect is the same as that of a full-wave antenna, as shown in figure 4-23, view A. The current in the first one-half wavelength is exactly 180 degrees out of phase with that in the second one-half wavelength. This is the opposite of the desired condition. In the illustration, arrows are used to indicate the direction of current flow in the

antenna. (Using arrows is a convenient means of determining the phase on more complicated arrays.)

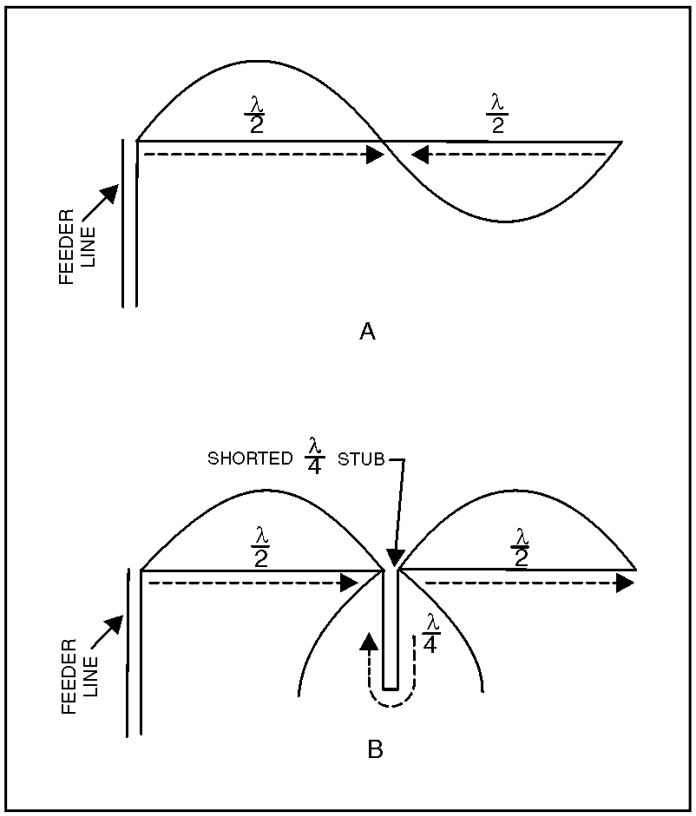

Figure 4-23. Phasing of Connected Elements

4-110. When the two elements are connected by a shorted one-quarter-wavelength stub, as shown in figure 4-23, view B, current travels down one side of the stub and up the other. It travels a distance of one-half wavelength in the stub itself. As a result, the current moves through one-half cycle of change. When the current reaches the second element, it is in the desired phase. Because the current on one side of the stub is equal and opposite to the current on the other side, the fields produced here cancel and no radiation is transmitted from the stub itself.

DIRECTIVITY

4-111. The directivity of an antenna or an array can be determined by looking at its radiation pattern. In an array propagating a given amount of energy, more radiation takes place in certain directions than in others. The elements in the array can be altered in such a way that they change the pattern and distribute it more uniformly in all directions. The elements can be considered as a group of antennas fed from a common source and facing different directions. On the other hand, the elements could be arranged so that the radiation would be focused in a single direction. With no increase in power from the transmitter, the amount of radiation in a given direction would be greater. Because the input power has no increase, this increased directivity is achieved at the expense of gain in other directions.

Directivity and Interference

4-112. In many applications, sharp directivity is desirable although no need exists for added gain. Examine the physical disposition of the units shown in figure 4-24. Transmitters 1 and 2 are sending information to receivers 1 and 2, respectively, along the paths shown by the solid arrows. The distance between transmitter 1 and receiver 1 or between transmitter 2 and receiver 2 is short and does not require high-power transmission. The antennas of the transmitters propagate well in all directions. However, receiver 1 picks up some of the signals from transmitter 2, and receiver 2 picks up some of the signals from transmitter 1, as shown by the broken arrows. This effect is emphasized if the receiving antennas intercept energy equally well in all directions.

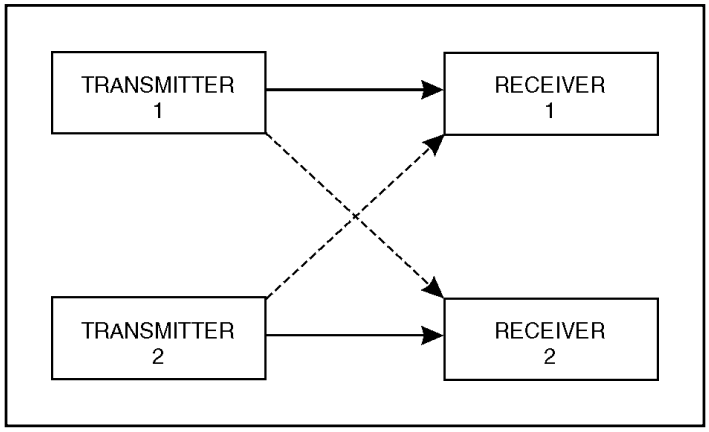

Figure 4-24. Directivity and Interference

4-113. The use of highly directional arrays as radiators from the transmitters tends to solve the problem. The signals are beamed along the paths of the solid arrows and provide very low radiation along the paths of the broken arrows. Further improvement along these lines is obtained by the use of narrowly directed arrays as receiving antennas. The effect of this arrangement is to select the desired signal while discriminating against all other signals. This same approach can be used to overcome other types of radiated interference. In such cases, preventing radiation in certain directions is more important than producing greater gain in other directions.

4-114. Look at the differences between the field patterns of the single-element antenna and the array, as illustrated in figure 4-25. View A shows the relative field-strength pattern for a horizontally polarized single antenna. View B shows the horizontal-radiation pattern for an array. The antenna in view A radiates fairly efficiently in the desired direction toward receiving point X. It radiates equally as efficiently toward Y, although no radiation is desired in this direction. The antenna in view B radiates strongly to point X, but very little in the direction of point Y, which results in more satisfactory operation.

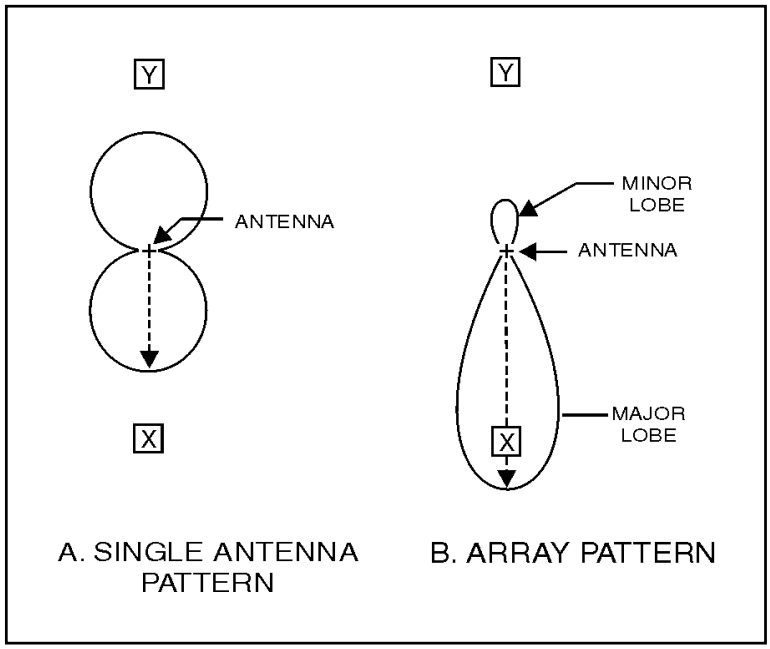

Figure 4-25. Single Antenna Versus Array

Major and Minor Lobes

4-115. The pattern shown in figure 4-25, view B has radiation concentrated in two lobes. The radiation intensity in one lobe is considerably stronger than in the other. The lobe toward point X is called a major lobe; the other is a minor lobe. Because the complex radiation patterns associated with arrays frequently contain several lobes of varying intensity, you should learn to use appropriate terminology. In general, major lobes are those in which the greatest amount of radiation occurs. Minor lobes are those in which the radiation intensity is least.

DIRECTIONAL ARRAYS

4-116. You have already learned about radiation patterns and directivity of radiation. These topics are important to you because using an antenna with an improper radiation pattern or with the wrong directivity will decrease the overall performance of the system. In the following paragraphs, we discuss in more detail the various types of directional antenna arrays mentioned earlier in this chapter.

Collinear Array

4-117. The pattern radiated by the collinear array is similar to that produced by a single dipole. The addition of the second radiator, however, tends to intensify the pattern. Compare the radiation pattern of the dipole (figure 4-26, view A) and the two-element antenna in view B. You will see that each pattern consists of two major lobes in opposite directions along the same axis, QQ1. There is little or no radiation along the PP1 axis. QQ1 represents the line of maximum propagation. You can see that radiation is stronger with an added element. The pattern in view B is sharper, or more directive, than that in view A. This means that the gain along the line of maximum energy propagation is increased and the beam width is decreased.

As more elements are added, the effect is heightened, as shown in view C. Unimportant minor lobes are generated as more elements are added.

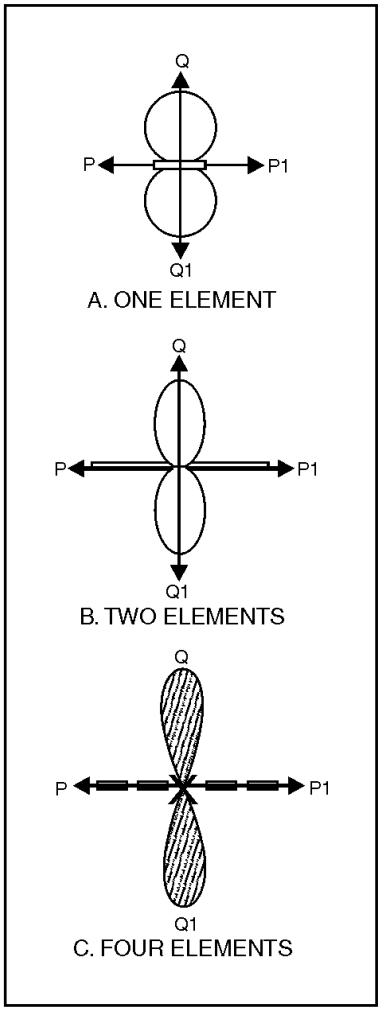

Figure 4-26. Single Half-Wave Antenna versus Two Half-Wave Antenna in Phase

4-118. More than four elements are seldom used because accumulated losses cause the elements farther from the point of feeding to have less current than the nearer ones. This introduces an unbalanced condition in the system and impairs its efficiency. Space limitations often are another reason for restricting the number of elements. Because this type of array is in a single line, rather than in a vertically stacked arrangement, the use of too many elements results in an antenna several wavelengths long.

4-119. **Radiation pattern**. The characteristic radiation pattern of a given array is obtained at the frequency or band of frequencies at which the system is resonant. The gain and directivity characteristics are lost when the antenna is not used at or near this frequency and the array tunes too sharply. A collinear antenna is more effective than an end-fire array when used off its tuned frequency. This feature is considered when transmission or reception is to be over a wide frequency band. When more than two elements are used, this advantage largely disappears.

4-120. **Length and phasing**. Although the one-half wavelength is the basis for the collinear element, you will find that greater lengths are often used. Effective arrays of this type have been constructed in which the elements are 0.7 and even 0.8 wavelength long. This type of array provides efficient operation at more than one frequency or over a wider frequency range. Whatever length is decided upon, all of the elements in a particular array should closely adhere to that length. If elements of different lengths are combined, current phasing and distribution are changed, throwing the system out of balance and seriously affecting the radiation pattern.

4-121. **Spacing**. The lower relative efficiency of collinear arrays of many elements, compared with other multi-element arrays, relates directly to spacing and mutual impedance effects. Mutual impedance is an important factor to be considered when any two elements are parallel and are spaced so that considerable coupling is between them. There is very little mutual impedance between collinear sections. Where impedance does exist, it is caused by the coupling between the ends of adjacent elements. Placing the ends of elements close together is frequently necessary because of construction problems, especially where long lengths of wire are involved.

4-122. The effects of spacing and the advantages of proper spacing can be demonstrated by some practical examples. A collinear array consisting of two half-wave elements with one-half-wavelength spacing between centers has a gain of 1.8 decibels (dB). If the ends of these same dipoles are separated so that the distance from center to center is three-quarters of a wavelength and they are driven from the same source, the gain increases to approximately 2.9 dB.

4-123. A three-dipole array with negligible spacing between elements gives a gain of 3.3 dB. In other words, when two elements are used with wider spacing, the gain obtained is approximately equal to the gain obtainable from three elements with close spacing. The spacing of this array permits simpler construction, because only two dipoles are used. It also allows the antenna to occupy less space. Construction problems usually dictate small-array spacing.

Broadside Arrays

4-124. A broadside array is shown in figure 4-27, view A. Physically, it looks somewhat like a ladder. When the array and the elements in it are polarized horizontally, it looks like an upright ladder. When the array is polarized vertically, it looks like a ladder lying on one side (view B). View C is an illustration of the radiation pattern of a broadside array. Horizontally polarized arrays using more than two elements are not common. This is because the requirement that the bottom of the array be a significant distance above the earth presents construction problems. Compared with collinear arrays, broadside arrays tune sharply, but lose efficiency rapidly when not operated on the frequencies for which they are designed.

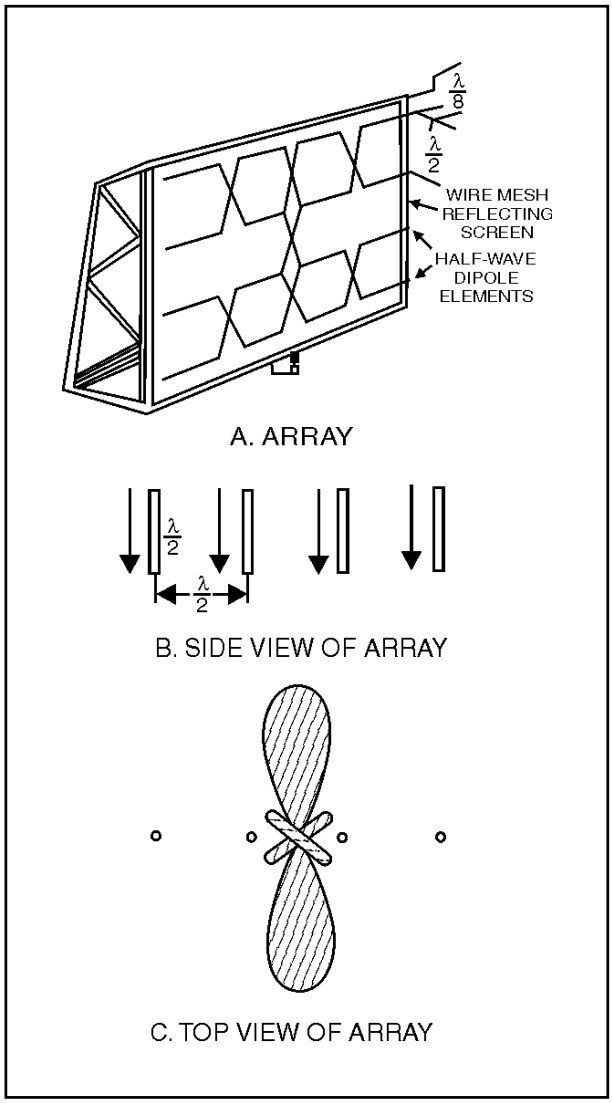

Figure 4-27. Typical Broadside Array

4-125. **Radiation pattern**. Figure 4-28 shows an end view of two parallel half-wave antennas (A and B) operating in the same phase and located one-half wavelength apart. At a point (P) far removed from the antennas, the antennas appear as a single point. Energy radiating toward P from antenna A starts out in phase with the energy radiating from antenna B in the same direction. Propagation from each antenna travels over the same distance to point P, arriving there in phase. The antennas reinforce each other in this direction, making a strong signal available at P. Field strength measured at P is greater than it would be if the total power supplied to both antennas had been fed to a single dipole. Radiation toward point P1 is built up in the same manner.

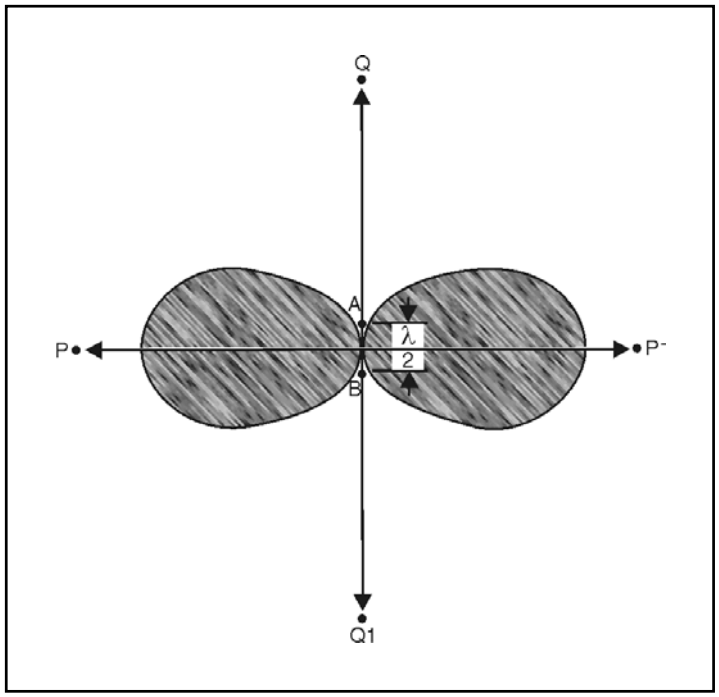

Figure 4-28. Parallel Elements in Phase

4-126. Next consider a wavefront traveling toward point Q from antenna B. By the time it reaches antenna A, one-half wavelength away, one-half cycle has elapsed. Therefore energy from antenna B meets the energy from antenna A 180 degrees out of phase. As a result, the energy moving toward point Q from the two sources cancels. In a like manner, radiation from antenna A traveling toward point Q1 meets and cancels the radiation in the same direction from antenna B. As a result, little propagation takes place in either direction along the QQ1 axis. Most of the energy is concentrated in both directions along the PP1 axis. When both antenna elements are fed from the same source, the result is the basic broadside array.

4-127. When more than two elements are used in a broadside arrangement, they are all parallel and in the same plane, as shown in figure 4-27, view B. Current phase, indicated by the arrows, must be the same for all elements. The radiation pattern shown in figure 4-27, view C, and is always bidirectional. This pattern is sharper than the one shown in figure 4-28 because of the additional two elements. Directivity and gain depend on the number of elements and the spacing between them.

4-128. **Gain and directivity**. The physical disposition of dipoles operated broadside to each other allows for much greater coupling between them than can occur between collinear elements. Moving the parallel antenna elements closer together or farther apart affects the actual impedance of the entire array and the overall radiation resistance as well. As the spacing between broadside elements increases, the effect on the radiation pattern is a sharpening of the major lobes. When the array consists of only two dipoles spaced exactly one-half wavelength apart, no minor lobes are generated at all. Increasing the distance between the elements beyond that point,

however, tends to throw off the phase relationship between the original current in one element and the current induced in it by the other element. The result is that, although the major lobes are sharpened, minor lobes are introduced, even with two elements. These minor lobes, however, are not large enough to be of concern.

4-129. If you add the same number of elements to both a broadside array and a collinear array, the gain of the broadside array will be greater. Reduced radiation resistance resulting from the efficient coupling between dipoles accounts for most of this gain. However, certain practical factors limit the number of elements that may be used. The construction problem increases with the number of elements, especially when they are polarized horizontally.

End-Fire Arrays

4-130. An end-fire array looks similar to a broadside array. The ladder-like appearance is characteristic of both (figure 4-29, view A). The currents in the elements of the end-fire array, however, are usually 180 degrees out of phase with each other as indicated by the arrows. The construction of the end-fire array is like that of a ladder lying on its side (elements horizontal). The dipoles in an end-fire array are closer together (one-eighth wavelength to one-quarter wavelength spacing) than they are for a broadside array.

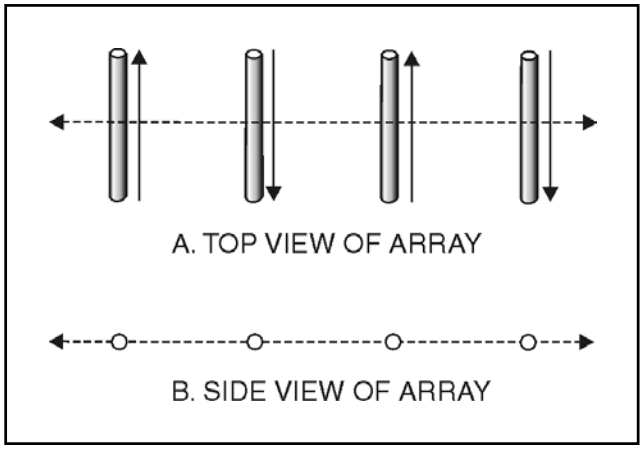

Figure 4-29. Typical End-Fire Array

4-131. Closer spacing between elements permits compactness of construction. For this reason, an end-fire array is preferred to other arrays when high gain or sharp directivity is desired in a confined space. However, the close coupling creates certain disadvantages. Radiation resistance is extremely low, sometimes as low as 10 ohms, making antenna losses greater. The end-fire array is confined to a single frequency. With changes in climatic or atmospheric conditions, the danger of detuning exists.

4-132. **Radiation pattern**. The radiation pattern for a pair of parallel half-wave elements fed 180 degrees out of phase is shown in figure 4-30, view A. The elements shown are spaced one-half wavelength apart. In practice, smaller spacings are used. Radiation from elements L and M traveling toward point P begins 180 degrees out of phase. Moving the same distance over approximately parallel paths, the respective wavefronts from these

elements remain 180 degrees out of phase. In other words, maximum cancellation takes place in the direction of P. The same condition is true for the opposite direction (toward P1). The P to P1 axis is the line of least radiation for the end-fire array.

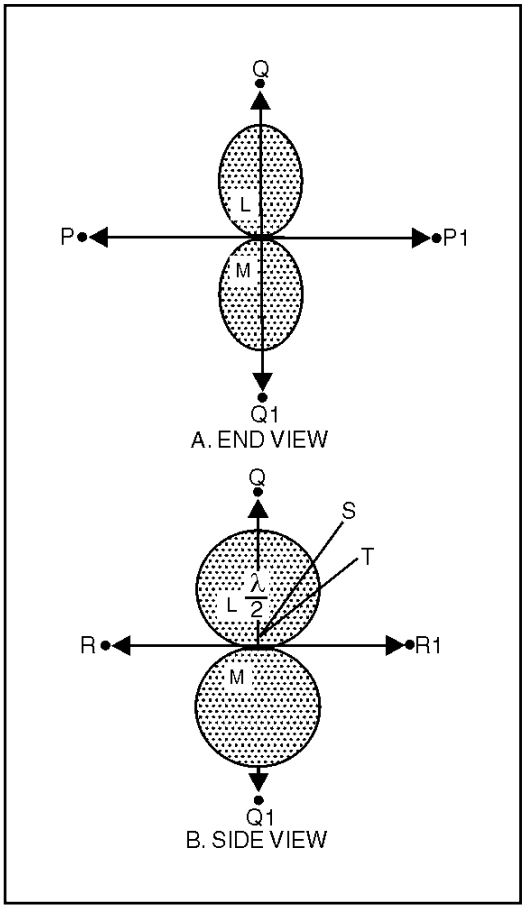

Figure 4-30. Parallel Elements 180 Degrees Out of Phase

4-133. Consider what happens along the QQ1 axis. Energy radiating from element M toward Q reaches element L in about one-half cycle (180 degrees) after it leaves its source. Because element L was fed 180 degrees out of phase with element M, the wavefronts are now in the same phase and are both moving toward Q and reinforcing each other. Similar reinforcement occurs along the same axis toward Q1. This simultaneous movement towards Q and Q1 develops a bidirectional pattern. This is not always true in end-fire operation. Another application of the end-fire principle is one in which the elements are spaced one-quarter wavelength apart and phased 90 degrees from each other to produce a unidirectional pattern.

4-134. In figure 4-30, view A, elements A and B are perpendicular to the plane represented by the page; therefore, only the ends of the antennas appear. In view B, the antennas are rotated a quarter of a circle in space around the QQ1 axis so that they are seen in the plane of the elements themselves. Therefore, the PP1 axis, now perpendicular to the page, is not

seen as a line. The RR1 axis, now seen as a line, is perpendicular to the PP1 axis as well as to the QQ1 axis. The end-fire array is directional in this plane also, although not quite as sharply. The reason for the greater broadness of the lobes can be seen by following the path of energy radiating from the midpoint of element B toward point S in view B. This energy passes the A element at one end after traveling slightly more than the perpendicular distance between the dipoles. Energy, therefore, does not combine in exact phase toward point S. Although maximum radiation cannot take place in this direction, energy from the two sources combines closely enough in phase to produce considerable reinforcement. A similar situation exists for wavefronts traveling toward T. However; the wider angle from Q to T produces a greater phase difference and results in a decrease in the strength of the combined wave.

4-135. Directivity occurs from either one or both ends of the end-fire array, along the axis of the array, as shown by the broken arrows in figure 4-29, view A; hence, the term end-fire is used.

4-136. The major lobe or lobes occur along the axis of the array. The pattern is sharper in the plane that is at right angles to the plane containing the elements (figure 4-30, view A). If the elements are not exact half-wave dipoles, operation is not significantly affected. However, because of the required balance of phase relationships and critical feeding, the array must be symmetrical. Folded dipoles, such as the one shown in figure 4-21, view A, are used frequently because the impedance at their terminals is higher. This is an effective way of avoiding excessive antenna losses. Another expedient to reduce losses is the use of tubular elements of wide diameter.

4-137. **Gain and directivity**. In end-fire arrays, directivity increases with the addition of more elements and with spacings approaching the optimum. The directive pattern for a two-element, bidirectional system is illustrated in figure 4-30. View A shows radiation along the array axis in a plane perpendicular to the dipoles, and view B shows radiation along the array axis in the plane of the elements. These patterns were developed with a 180-degree phase difference between the elements. Additional elements introduce small, minor lobes.

4-138. With a 90-degree phase difference in the energy fed to a pair of end-fire elements spaced approximately one-quarter wavelength apart, unidirectional radiation can be obtained. The pattern perpendicular to the plane of the two elements is shown in figure 4-31, view A. The pattern shown in view B, taken in the same plane, is for a six-element array with 90-degree phasing between adjacent elements. Because both patterns show relative gain only, the increase in gain produced by the six-element array is not evident. End-fire arrays are the only unidirectional arrays wholly made up of driven elements.

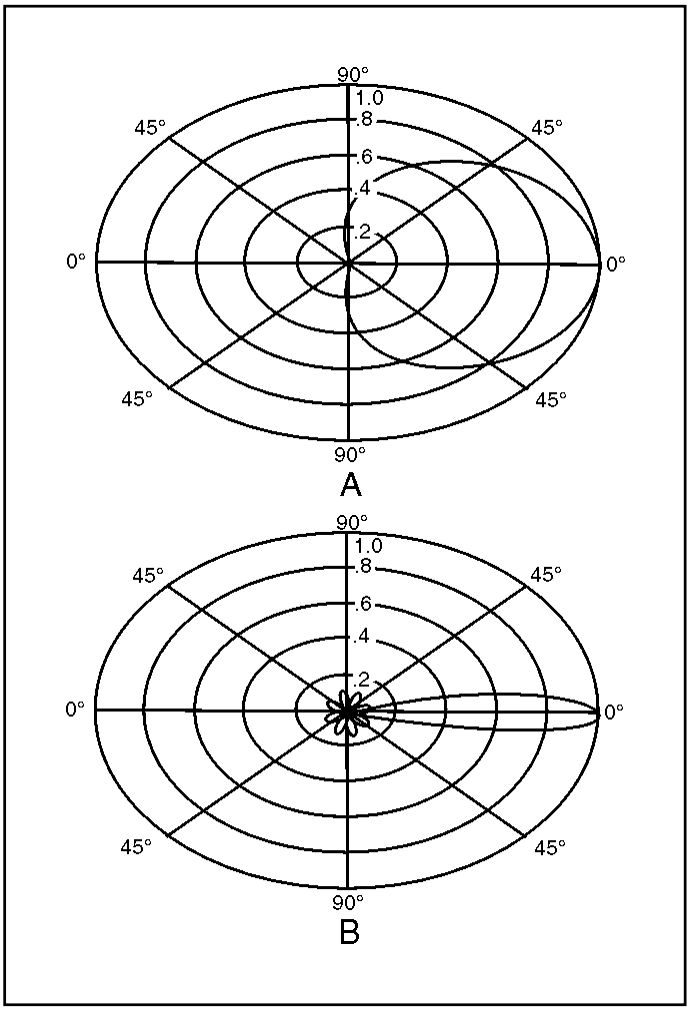

Figure 4-31. Unidirectional End-Fire Arrays

Parasitic Arrays

4-139. If a small light bulb were placed in the center of a large room, the illumination would be very poor. However, if a reflector were placed behind the bulb, the space in front of the reflector would be brighter and the space behind the reflector would be dimmer. The light rays would be concentrated. Also, if a lens were placed in front of the bulb, the light would be even more concentrated and a very bright spot would appear on the wall in front of the lens. A flashlight is a practical combination of the small bulb, the reflector, and the lens. The energy from an antenna can be reflected and concentrated in a similar manner.

4-140. Although we do not usually discuss the gain of a flashlight, we can continue the comparison of an antenna and a flashlight to explain the meaning of antenna gain. Suppose the spot on the wall in front of the flashlight becomes 10 times brighter than it was when only the open bulb was used. The lens and reflector have then produced a 10-fold gain in light. For antennas, the simple half-wave antenna corresponds to the open bulb in

the flashlight. Suppose an antenna system concentrates the radio waves so that at a particular point the field strength is 10 times more than it would be at the same distance from a half-wave antenna. The antenna system is then said to have a gain of 10.

4-141. Parasitic arrays represent another method of achieving high antenna gains. A parasitic array consists of one or more parasitic elements placed in parallel with each other and, in most cases, at the same line-of-sight level. The parasitic element is fed inductively by radiated energy coming from the driven element connected to the transmitter. It is in no way connected directly to the driven element.

4-142. When the parasitic element is placed so that it radiates away from the driven element, the element is a director. When the parasitic element is placed so that it radiates toward the driven element, the parasitic element is a reflector.

4-143. The directivity pattern resulting from the action of parasitic elements depends on two factors:

- The tuning determined by the length of the parasitic element.
- The spacing between the parasitic and driven elements.

To a lesser degree, the directivity pattern also depends on the diameter of the parasitic element, because diameter has an effect on tuning.

4-144. **Operation**. When a parasitic element is placed a fraction of a wavelength away from the driven element and is of approximately resonant length, it will re-radiate the energy it intercepts. The parasitic element is effectively a tuned circuit coupled to the driven element, much as the two windings of a transformer are coupled together. The radiated energy from the driven element causes a voltage to be developed in the parasitic element, which, in turn, sets up a magnetic field. This magnetic field extends over to the driven element, which then has a voltage induced in it. The magnitude and phase of the induced voltage depend on the length of the parasitic element and the spacing between the elements. In actual practice the length and spacing are arranged so that the phase and magnitude of the induced voltage cause a unidirectional, horizontal-radiation pattern and an increase in gain.

4-145. In the parasitic array in figure 4-32, view A, the parasitic and driven elements are spaced one-quarter wavelength apart. The radiated signal coming from the driven element strikes the parasitic element after one-quarter cycle. The voltage developed in the parasitic element is 180 degrees out of phase with that of the driven element. This is because of the distance traveled (90 degrees) and because the induced current lags the inducing flux by 90 degrees (90 + 90 = 180 degrees). The magnetic field set up by the parasitic element induces a voltage in the driven element one-quarter cycle later because the spacing between the elements is one-quarter wavelength. This induced voltage is in phase with that in the driven element and causes an increase in radiation in the direction indicated in figure 4-32, view A. Because the direction of the radiated energy is stronger in the direction away from the parasitic element (toward the driven element), the parasitic element is called a reflector. The radiation pattern as it would appear if you were looking down on the antenna is shown in view B. The pattern as it would look if viewed from the ends of the elements is shown in view C.

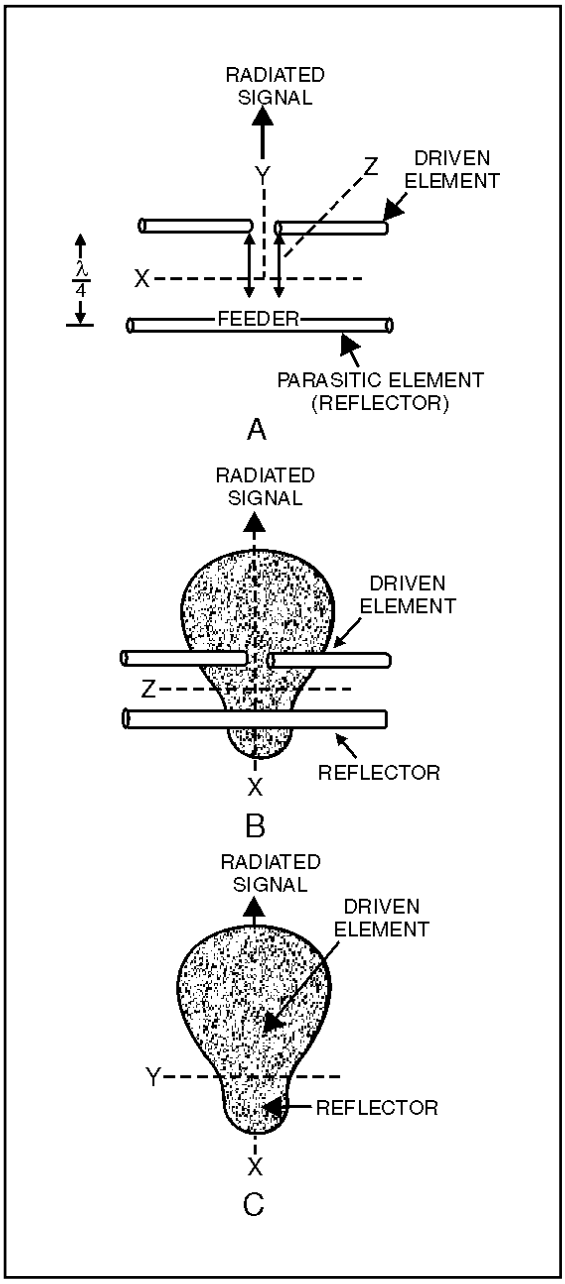

Figure 4-32. Patterns Obtained Using a Reflector with Proper Spacing

4-146. Because the voltage induced in the reflector is 180 degrees out of phase with the signal produced at the driven element, a reduction in signal strength exists behind the reflector. Because the magnitude of an induced voltage never quite equals that of the inducing voltage, even in very closely coupled circuits, the energy behind the reflector (minor lobe) is not reduced to 0.

4-147. The spacing between the reflector and the driven element can be reduced to about 15 percent of a wavelength. The parasitic element must be

made electrically inductive before it will act as a reflector. If this parasitic element is made about 5 percent longer than one-half wavelength, it will act as a reflector when the spacing is 15 percent of a wavelength.

4-148. Changing the spacing and length can change the radiation pattern so that maximum radiation is on the same side of the driven element as the parasitic element. In this instance, the parasitic element is called a director.

4-149. Combining a reflector and a director with the driven element causes a decrease in back radiation and an increase in directivity. This combination results in the two main advantages of a parasitic array—unidirectivity and increased gain. If the parasitic array is rotated, it can pick up or transmit in different directions because of the reduction of transmitted energy in all but the desired direction. An antenna of this type is called a rotary array. Size for size, both the gain and directivity of parasitic arrays are greater than those of driven arrays. The disadvantage of parasitic arrays is that their adjustment is critical and they do not operate over a wide frequency range.

4-150. **Gain and directivity**. Changing the spacing between either the director or the reflector and the driven element results in a change in the radiation pattern. More gain and directivity are obtained by changing the length of the parasitic elements.

4-151. The front-to-back ratio of an array is the proportion of energy radiated in the principal direction of radiation to the energy radiated in the opposite direction. A high front-to-back ratio is desirable because this means that a minimum amount of energy is radiated in the undesired direction. Because completely suppressing all such radiation is impossible, an infinite ratio cannot be achieved. In actual practice, however, rather high values can be attained. Usually the length and spacing of the parasitic elements are adjusted so that a maximum front-to-back ratio is obtained, rather than maximum gain in the desired direction.

Multi-Element Parasitic Array

4-152. A multi-element parasitic array is one that contains two or more parasitic elements with the driven element. If the array contains two parasitic elements (a reflector and a director) in addition to the driven element, it is usually known as a three-element array. If three parasitic elements are used, the array is known as a four-element array, and so on. Generally speaking, if more parasitic elements are added to a three-element array, each added element is a director. The field behind a reflector is so small that additional reflectors would have little effect on the overall radiation pattern. In radar, from one to five directors are used.

4-153. **Construction**. The parasitic elements of a multi-element parasitic array usually are positioned as shown in figure 4-33, views A and B. Proper spacings and lengths are determined experimentally. A folded dipole (view B) is often used as the driven element to obtain greater values of radiation resistance.

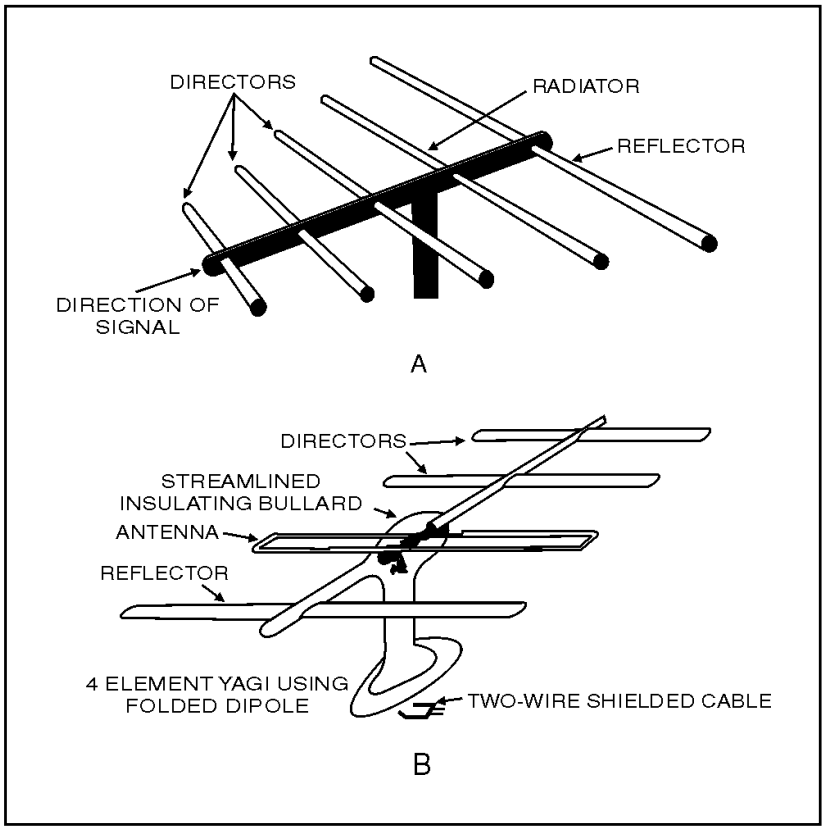

Figure 4-33. Yagi Antenna

4-154. **Yagi antennas**. An example of a multi-element parasitic array is the yagi antenna (figure 4-33, views A and B). The spacings between the elements are not uniform. The radiation from the different elements arrives in phase in the forward direction, but out of phase by various amounts in the other directions.

4-155. The director and the reflector in the yagi antenna are usually welded to a conducting rod or tube at their centers. This support does not interfere with the operation of the antenna. Because the driven element is center-fed, it is not welded to the supporting rod. Using a folded dipole as the driven element can increase the center impedance.

4-156. The yagi antenna shown in figure 4-33, view A, has three directors. In general, the greater number of parasitic elements used, the greater the gain. However, a greater number of such elements cause the array to have a narrower frequency response as well as a narrower beam width. Therefore, proper adjustment of the antenna is critical. The gain does not increase directly with the number of elements used. For example, a three-element yagi array has a relative power gain of 5 dB. Adding another director results in a 2 dB increase. Additional directors have less and less effect.

4-157. A typical yagi array used for receiving and transmitting energy is shown with a support frame in figure 4-34. This antenna is used by the military services. It operates at frequencies of from 12 to 50 megahertz and

consists of two separate arrays (one high frequency and one low frequency antenna array) mounted on one frame. The various elements are indicated in the figure. The high-frequency (HF) array consists of one reflector, one driven element, and two directors; the low-frequency (LF) array has the same arrangement with one less director. The lengths of the elements in the high-frequency array are shorter than those in the low-frequency array. The physical lengths of the elements in the individual arrays are equal, but the electrical lengths can be varied by means of the tuning stubs at the center of the elements. The array can be rotated in any desired direction by a remotely controlled, electrically driven, antenna rotator.

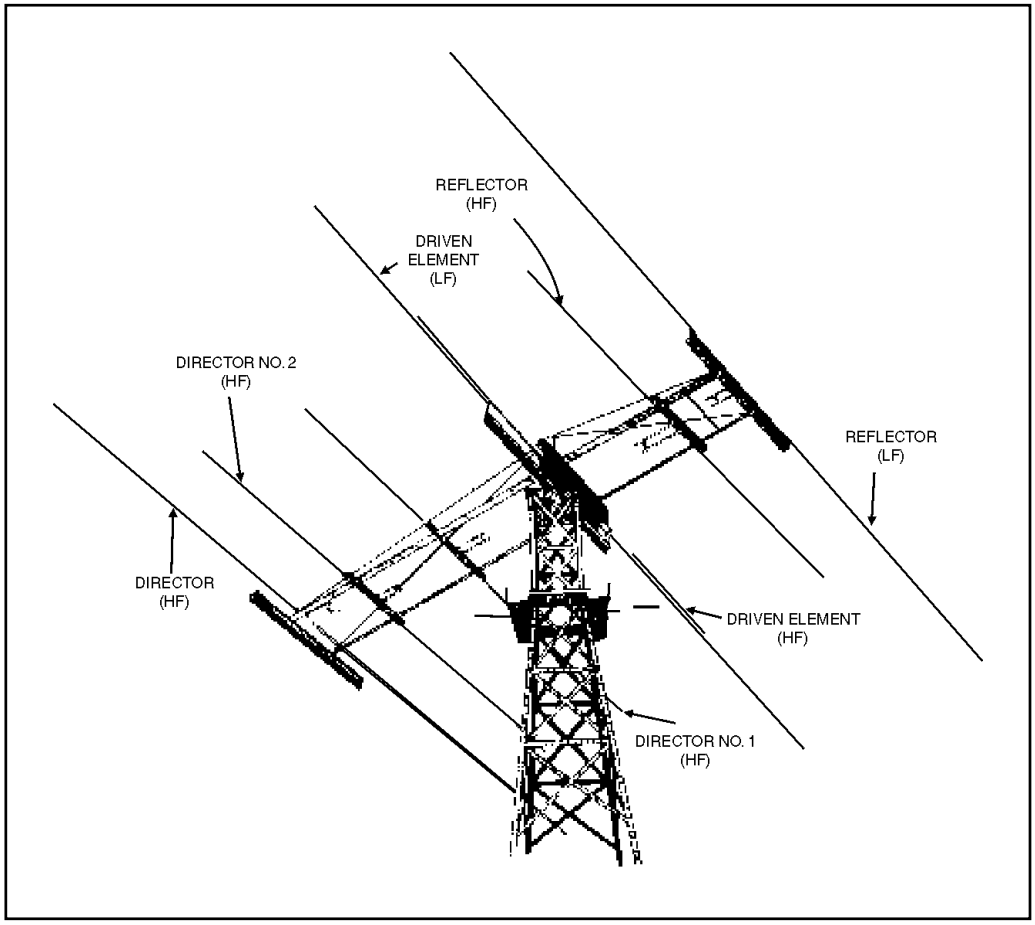

Figure 4-34. Typical Parasitic Array Used for Transmitting and Receiving

SPECIAL ANTENNAS

4-158. In this section we cover some special communications and radar antennas. Some of these antennas we touch on only briefly because they are covered thoroughly in other courses.

4-159. Previously discussed antennas operate with standing waves of current and voltage along the wires. This section deals principally with antenna systems in which the current is practically uniform in all parts of the antenna. In its basic form, such an antenna consists of a single wire grounded at the far end through a resistor. The resistor has a value equal to

the characteristic impedance of the antenna. This termination, just as in the case of an ordinary transmission line, eliminates standing waves. The current, therefore, decreases uniformly along the wire as the terminated end is approached. This decrease is caused by the loss of energy through radiation. The energy remaining at the end of the antenna is dissipated in the terminating resistor. For such an antenna to be a good radiator, its length must be fairly long. Also, the wire must not be too close to the ground. The return path through the ground will cause cancellation of the radiation. If the wire is sufficiently long, it will be practically nonresonant over a wide range of operating frequencies.

Long-Wire Antenna

4-160. A long-wire antenna is an antenna that is one wavelength or longer at the operating frequency. In general, the gain achieved with long-wire antennas is not as great as the gain obtained from the multi-element arrays studied in the previous section. But the long-wire antenna has advantages of its own. The construction of long-wire antennas is simple, both electrically and mechanically, with no particularly critical dimensions or adjustments. The long-wire antenna will work well and give satisfactory gain and directivity over a frequency range up to twice the value for which it was cut. In addition, it will accept power and radiate it efficiently on any frequency for which its overall length is not less than approximately one-half wavelength. Another factor is that long-wire antennas have directional patterns that are sharp in both the horizontal and vertical planes. Also, they tend to concentrate the radiation at the low vertical angles.

4-161. Another type of long-wire antenna is the beverage antenna, also called a wave antenna. It is a horizontal, long-wire antenna designed especially for the reception and transmission of low frequency, vertically polarized ground waves. It consists of a single wire, two or more wavelengths long, supported 3 to 6 meters above the ground, and terminated in its characteristic impedance, as shown in figure 4-35.

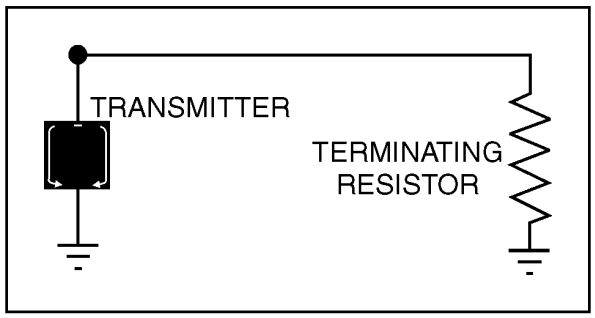

Figure 4-35. Beverage Antenna

V Antenna

4-162. A V antenna is a bidirectional antenna used widely in military and commercial communications. It consists of two conductors arranged to form a V. Each conductor is fed with currents of opposite polarity.

4-163. The V is formed at such an angle that the main lobes reinforce along the line bisecting the V and make a very effective directional antenna (see

figure 4-36). Connecting the two-wire feed line to the apex of the V and exciting the two sides of the V 180 degrees out of phase causes the lobes to add along the line of the bisector and to cancel in other directions, as shown in figure 4-37. The lobes are designated 1, 2, 3, and 4 on leg AA', and 5, 6, 7, and 8 on leg BB'. When the proper angle between AA' and BB' is chosen, lobes 1 and 4 have the same direction and combine with lobes 7 and 6, respectively. This combination of two major lobes from each leg results in the formation of two stronger lobes, which lie along an imaginary line bisecting the enclosed angle. Lobes 2, 3, 5, and 8 tend to cancel each other, as do the smaller lobes, which are approximately at right angles to the wire legs of the V. The resultant waveform pattern is shown at the right of the V antenna in figure 4-37.

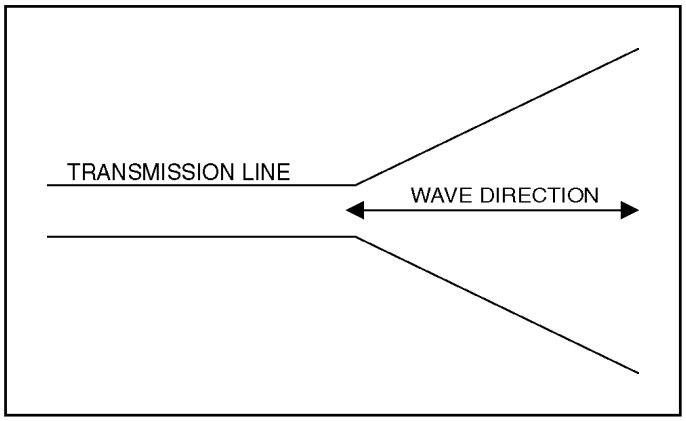

Figure 4-36. Basic V Antenna

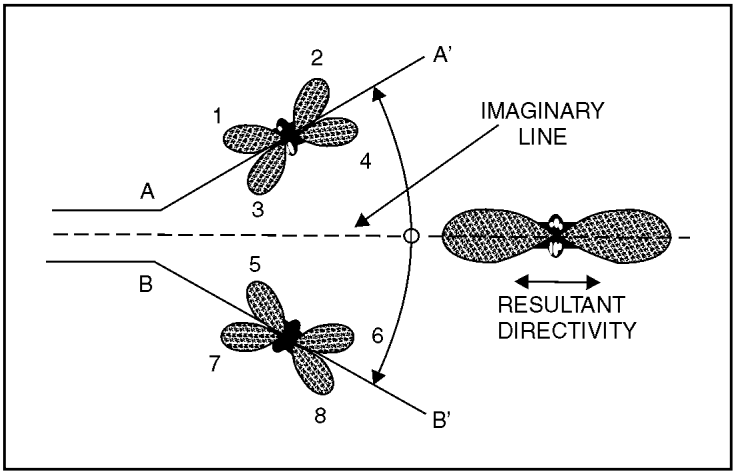

Figure 4-37. Formation of Directional Radiation from a Resonant V Antenna

Rhombic Antenna

4-164. The highest development of the long-wire antenna is the rhombic antenna (see figure 4-38). It consists of four conductors joined to form a rhombus, or diamond shape. The antenna is placed end to end and

terminated by a noninductive resistor to produce a unidirectional pattern. A rhombic antenna can be made of two obtuse-angle V antennas that are placed side by side, erected in a horizontal plane, and terminated so the antenna is nonresonant and unidirectional. The rhombic antenna is widely used for long-distance, high-frequency transmission and reception. It is one of the most popular fixed-station antennas because it is very useful in point-to-point communications.

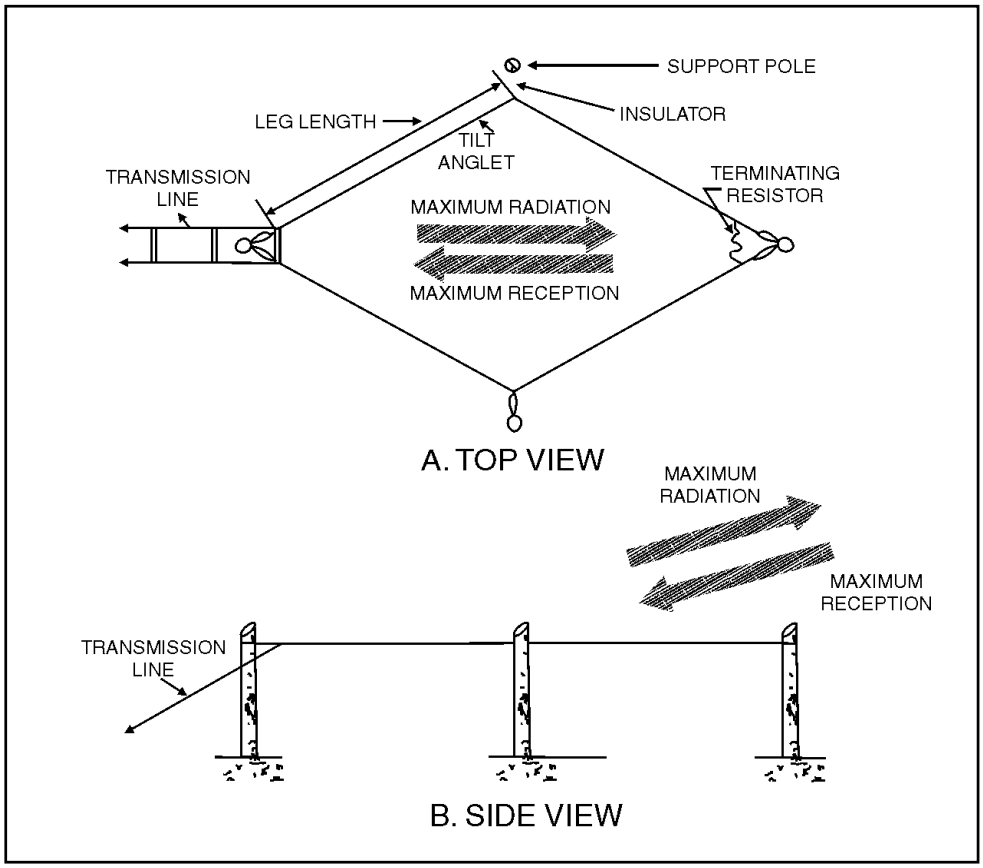

Figure 4-38. Basic Rhombic Antenna

4-165. **Advantages**. The rhombic antenna is useful over a wide frequency range. Although some changes in gain, directivity, and characteristic impedance do occur with a change in operating frequency, these changes are small enough to be ignored.

4-166. The rhombic antenna is much easier to construct and maintain than other antennas of comparable gain and directivity. Only four supporting poles of common heights from 15 to 20 meters are needed for the antenna.

4-167. The rhombic antenna also has the advantage of being noncritical as far as operation and adjustment are concerned. This is because of the broad frequency characteristics of the antenna.

4-168. Still another advantage is that the voltages present on the antenna are much lower than those produced by the same input power on a resonant

antenna. This is particularly important when high transmitter powers are used or when high-altitude operation is required.

4-169. **Disadvantages**. The rhombic antenna is not without its disadvantages. The principal one is that a fairly large antenna site is required for its erection. Each leg is made at least 1 or 2 wavelengths long at the lowest operating frequency. When increased gain and directivity are required, legs of from 8 to 12 wavelengths are used. These requirements mean that high-frequency rhombic antennas have wires of several hundred feet in length. Therefore, they are used only when a large plot of land is available.

4-170. Another disadvantage is that the horizontal and vertical patterns depend on each other. If a rhombic antenna is made to have a narrow horizontal beam, the beam is also lower in the vertical direction. Therefore, obtaining high vertical-angle radiation is impossible except with a very broad horizontal pattern and low gain. Rhombic antennas are used, however, for long-distance skywave coverage at the high frequencies. Under these conditions low vertical angles of radiation (less than 20 degrees) are desirable. With the rhombic antenna, a considerable amount of the input power is dissipated uselessly in the terminating resistor. However, this resistor is necessary to make the antenna unidirectional. The great gain of the antenna more than makes up for this loss.

4-171. **Radiation patterns**. Figure 4-39 shows the individual radiation patterns produced by the four legs of the rhombic antenna and the resultant radiation pattern. The principle of operation is the same as for the V and the half-rhombic antennas.

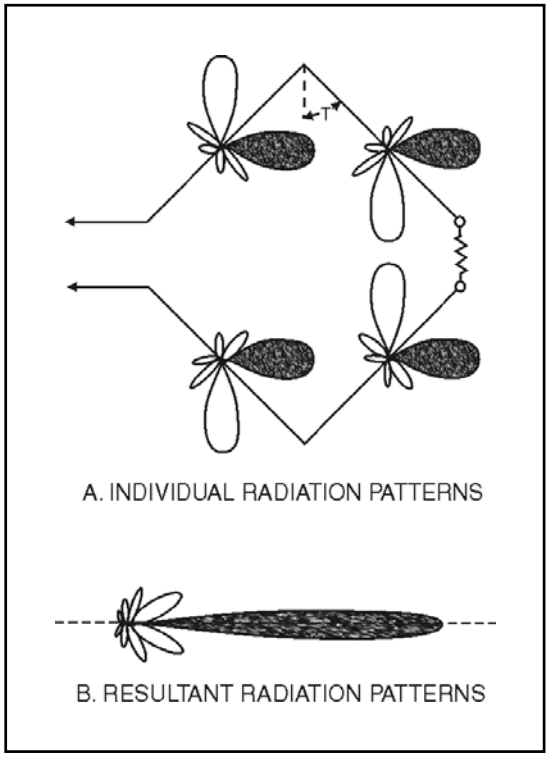

Figure 4-39. Formation of a Rhombic Antenna Beam

4-172. **Terminating resistor**. The terminating resistor plays an important part in the operation of the rhombic antenna. Upon it depend the unidirectivity of the antenna and the lack of resonance effects. An antenna should be properly terminated so it will have constant impedance at its input. Terminating the antenna properly will also allow it to be operated over a wide frequency range without needing to change the coupling adjustments at the transmitter. The reduction of back radiation is perhaps of lesser importance for transmission. When an antenna is terminated with resistance, the energy that would be radiated backward is absorbed in the resistor.

Turnstile Antenna

4-173. The turnstile antenna is one of the many types that has been developed primarily for omnidirectional VHF communications. The basic turnstile consists of two horizontal half-wave antennas mounted at right angles to each other in the same horizontal plane. When these two antennas are excited with equal currents 90 degrees out of phase, the typical figure-eight patterns of the two antennas merge to produce the nearly circular pattern shown in figure 4-40, view A. Pairs of such antennas are frequently stacked, as shown in figure 4-41. Each pair is called a bay. In figure 4-41 two bays are spaced one-half wavelength apart. Their corresponding elements are excited in phase. These conditions cause a part of the vertical radiation from each bay to cancel that of the other bay. This cancellation results in a decrease in energy radiated at high vertical angles and increases the energy radiated in the horizontal plane. Stacking a number of bays can alter the vertical radiation pattern, causing a substantial gain in a horizontal direction without altering the overall horizontal directivity pattern. Figure 4-40, view B, compares the circular vertical radiation pattern of a single-bay turnstile with the sharp pattern of a four-bay turnstile array. A three-dimensional radiation pattern of a four-bay turnstile antenna is shown in figure 4-40, view C.

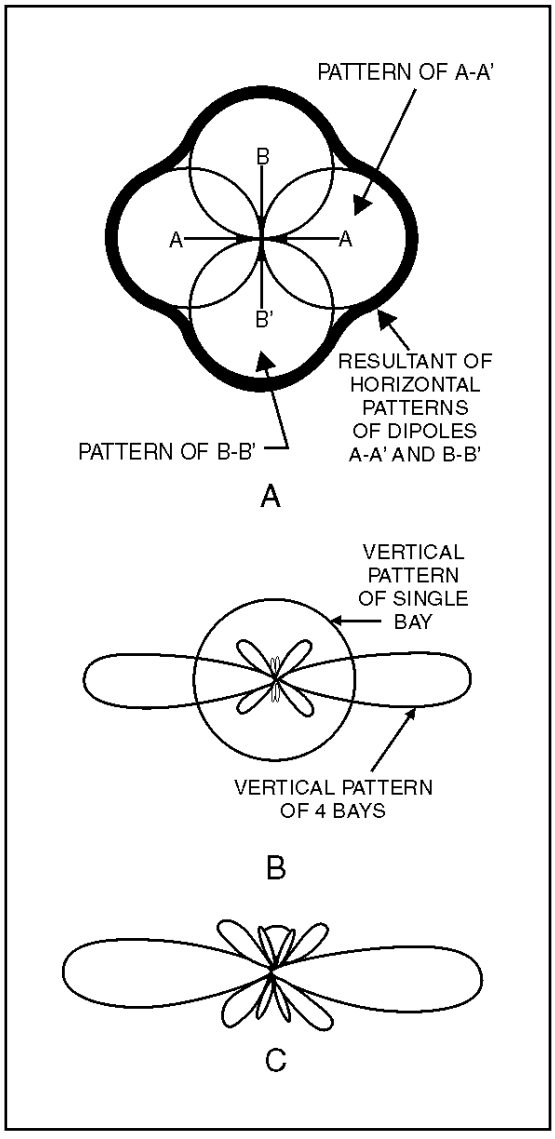

Figure 4-40. Turnstile Antenna Radiation Pattern

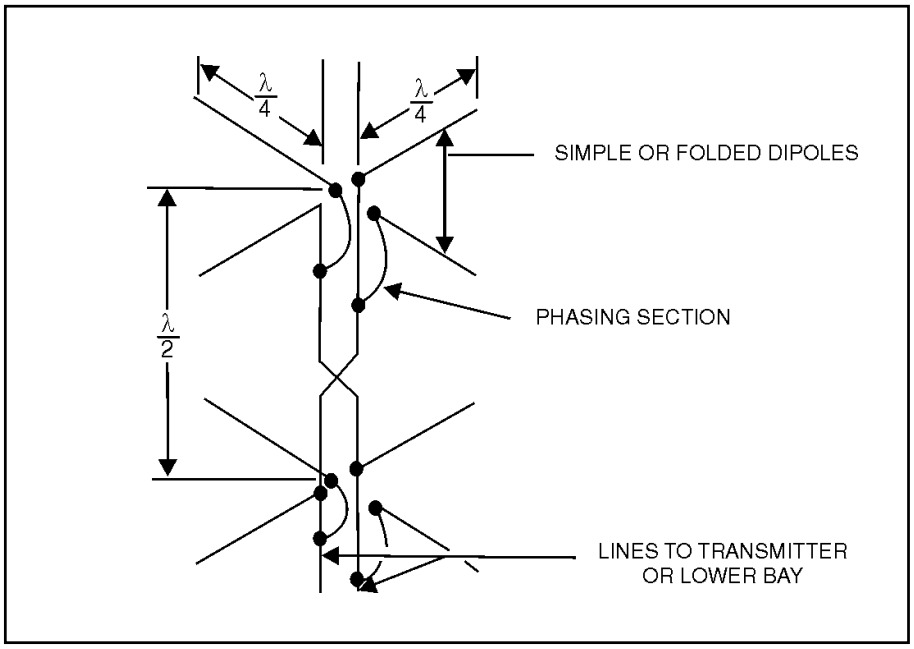

Figure 4-41. Stacked Turnstile Antenna

Ground-Plane Antenna

4-174. A vertical quarter-wave antenna several wavelengths above ground produces a high angle of radiation that is very undesirable at VHF and UHF frequencies. The most common means of producing a low angle of radiation from such an antenna is to work the radiator against a simulated ground called a ground plane. A simulated ground may be made from a large metal sheet or several wires or rods radiating from the base of the radiator. An antenna so constructed is known as a ground-plane antenna. Two ground-plane antennas are shown in figure 4-42, views A and B.

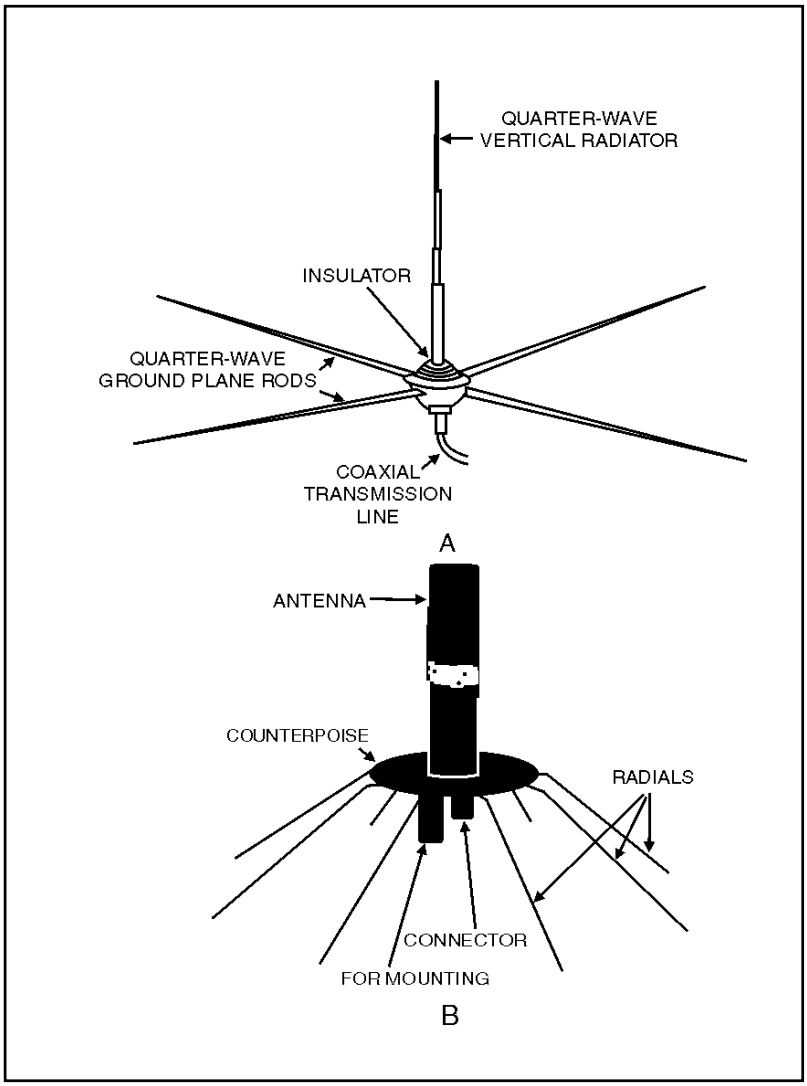

Figure 4-42. Ground-Plane Antenna

Corner Reflector

4-175. When a unidirectional radiation pattern is desired, it can be obtained by using a corner reflector with a half-wave dipole. A corner-reflector antenna is a half-wave radiator with a reflector. The reflector consists of two flat metal surfaces meeting at an angle immediately behind the radiator. In other words, the radiator is set in the plane of a line bisecting the corner angle formed by the reflector sheets. The construction of a corner reflector is shown in figure 4-43, view B Corner-reflector antennas are mounted with the radiator and the reflector in the horizontal position when horizontal polarization is desired. In such cases the radiation pattern is very narrow in the vertical plane, with maximum signal being radiated in line with the bisector of the corner angle. The directivity in the horizontal plane is approximately the same as for any half-wave radiator having a single-rod type reflector behind it. If the antenna is mounted with the radiator and the corner reflector in the vertical position, as shown in view A, maximum

radiation is produced in a very narrow horizontal beam. Radiation in a vertical plane will be the same as for a similar radiator with a single-rod type reflector behind it.

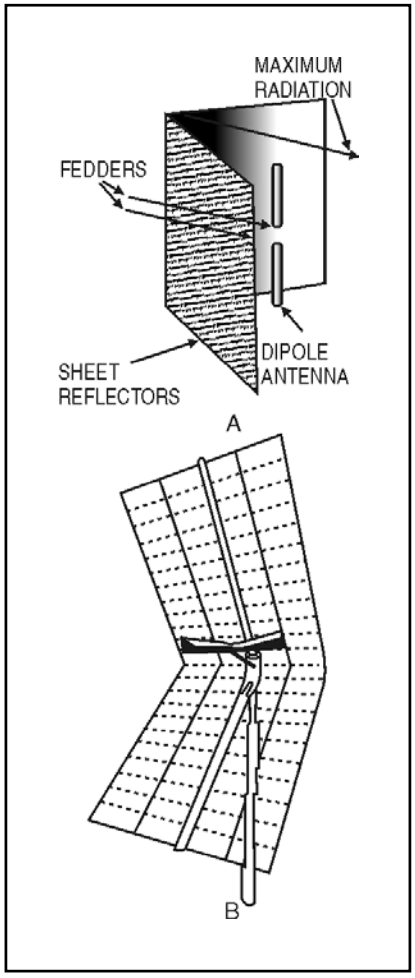

Figure 4-43. Corner-Reflector Antenna

SUMMARY

This chapter has presented information on the various types of antennas. The information that follows summarizes the important points of this chapter.

An antenna is a conductor, or system of conductors, that radiates or receives energy in the form of electromagnetic waves.

Hertz (half-wave) and Marconi (quarter-wave) are the two basic classifications of antennas.

Reciprocity of antennas means that the various properties of the antenna apply equally to transmitting and receiving.

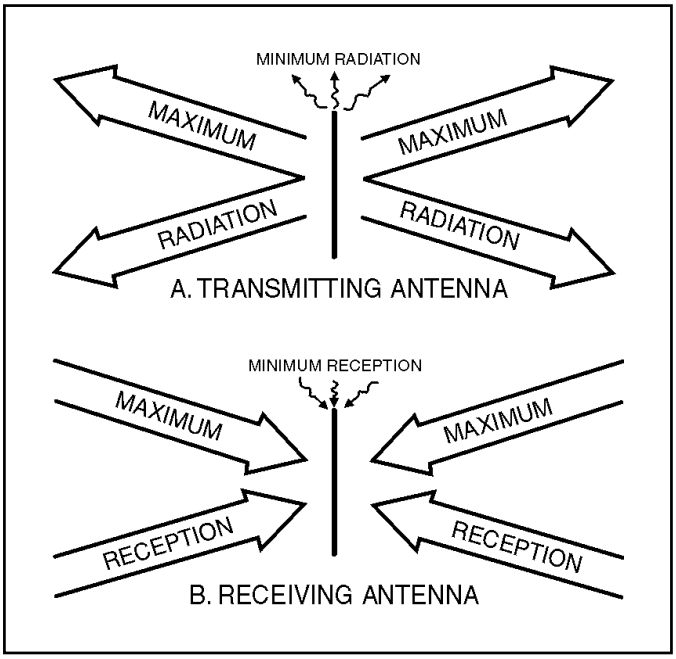

Figure 4-Sum 1. Reciprocity of Antennas

Radiation resistance is the amount of resistance that, if inserted in place of the antenna, would consume the same amount of power that is actually radiated by the antenna.

Radiation patterns can be plotted on a rectangular or polar-coordinate graph. These patterns are a measurement of the energy leaving an antenna.

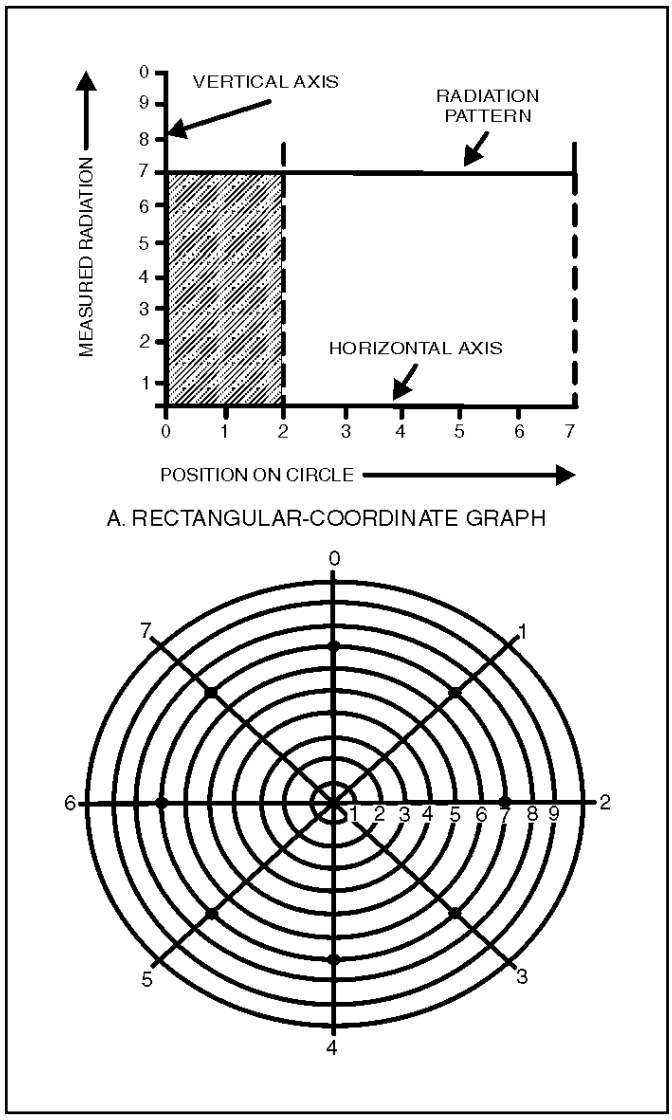

Figure 4-Sum 2. Radiation Patterns

An isotropic radiator radiates energy equally in all directions.

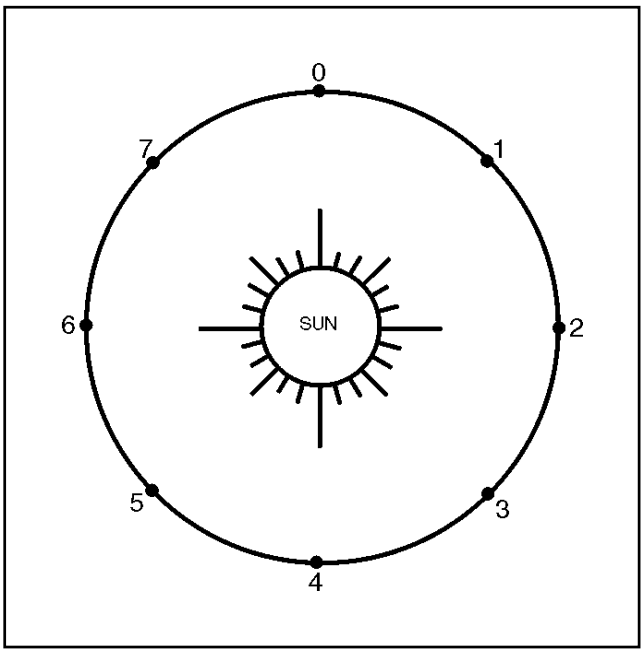

Figure 4-Sum 3. Radiating Energy of an Isotropic Radiator

An anisotropic radiator radiates energy directionally.

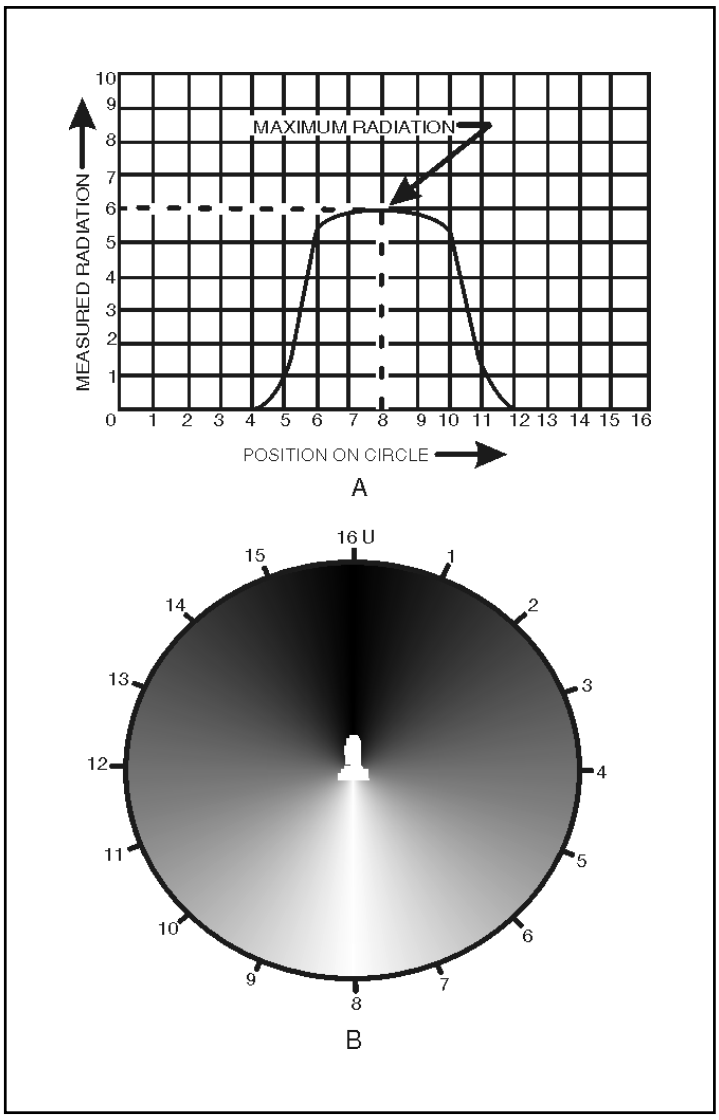

Figure 4-Sum 4. Directional Radiating Energy of an Anisotropic Radiator

A lobe is the area of a radiation pattern that is covered by radiation.

A null is the area of a radiation pattern that has minimum radiation.

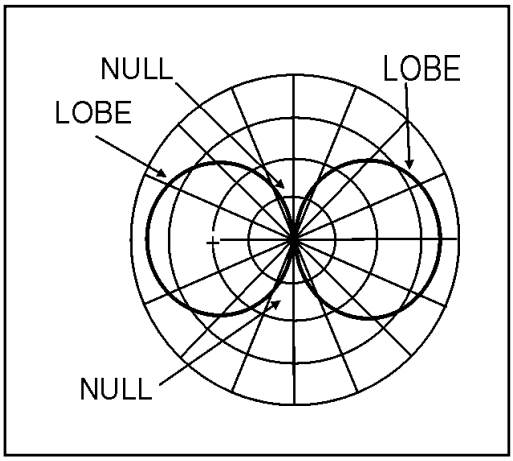

Figure 4-Sum 5. Null and Lobe Radiation Patterns

Antenna loading is the method used to change the electrical length of an antenna. This keeps the antenna in resonance with the applied frequency. It is accomplished by inserting a variable inductor or capacitor in series with the antenna.

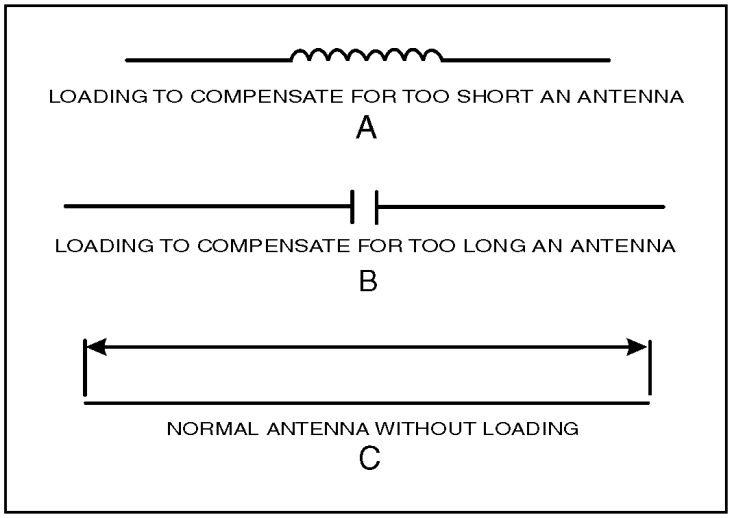

Figure 4-Sum 6. Antenna Loading

A half-wave antenna (Hertz) consists of two lengths of rod or tubing, each a quarter-wavelength long at a certain frequency, that radiate a doughnut pattern.

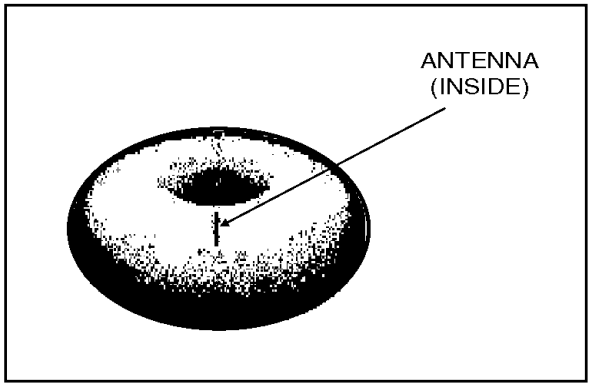

Figure 4-Sum 7. Half-Wave Antenna Pattern

A quarter-wave antenna (Marconi) is a half-wave antenna cut in half with one end grounded. The ground furnishes the missing half of the antenna.

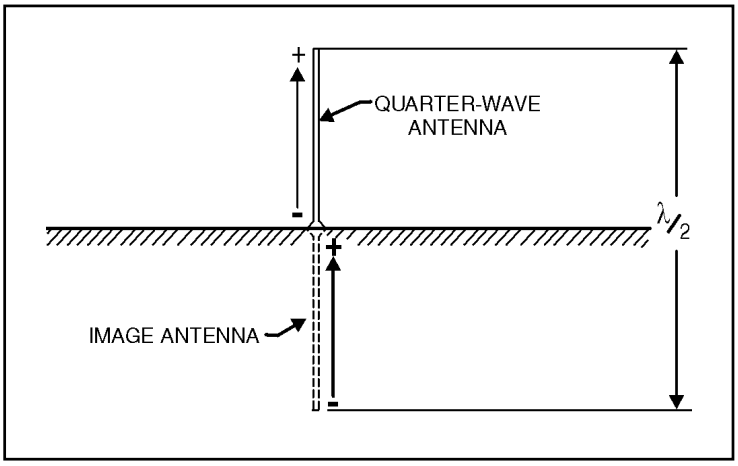

Figure 4-Sum 8. Quarter-Wave Antenna

The ground screen and the counterpoise are used to reduce losses caused by the ground in the immediate vicinity of the antenna. The ground screen is buried below the surface of the earth. The counterpoise is installed above the ground.

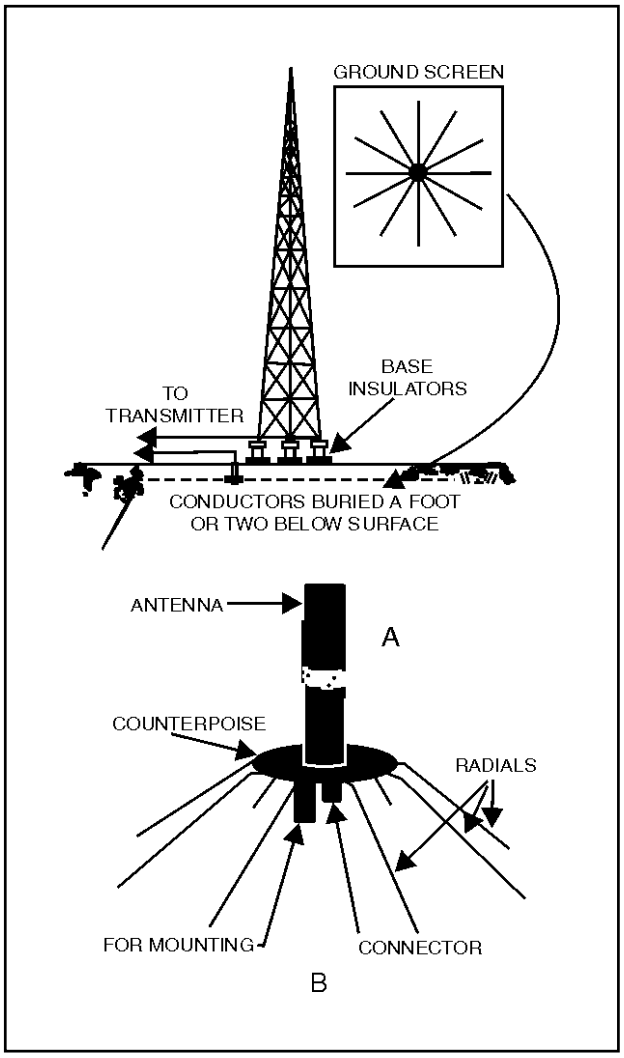

Figure 4-Sum 9. Ground Screen and Counterpoise Antennas

The folded dipole consists of a dipole radiator, which is connected in parallel at its ends to a half-wave radiator.

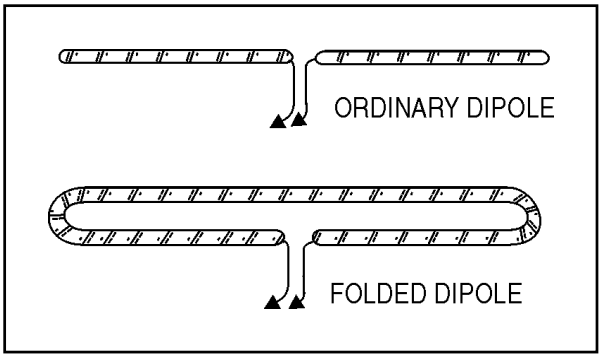

Figure 4-Sum 10. Folded Dipole

An array is a combination of half-wave elements operating together as a single antenna. It provides more gain and greater directivity than single element antennas.

A driven array derives its power directly from the source.

A parasitic array derives its power by coupling the energy from other elements of the antenna.

The bidirectional array radiates energy equally in two opposing directions.

The unidirectional array radiates energy efficiently in a single direction.

The collinear array has elements in a straight line. Maximum radiation occurs at right angles to this line.

The broadside array has elements parallel and in the same plane. Maximum radiation develops in the plane at right angles to the plane of the elements.

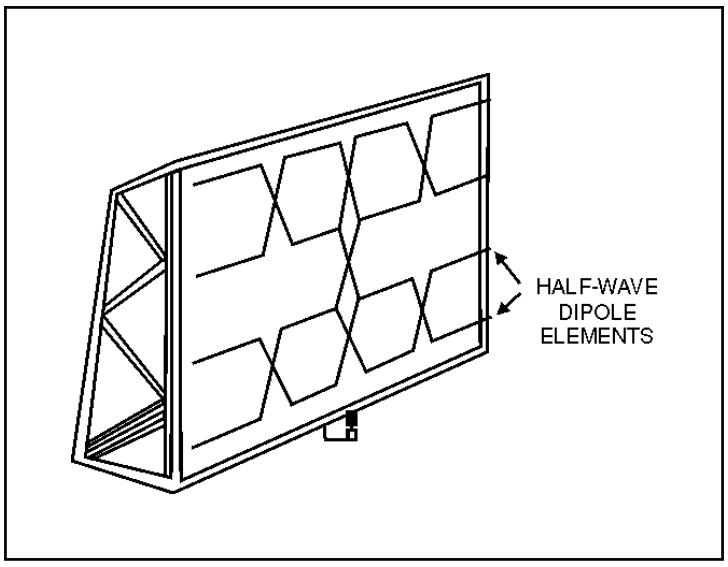

Figure 4-Sum 11. Broadside Array Elements

The end-fire array has elements parallel to each other and in the same plane. Maximum radiation occurs along the axis of the array.

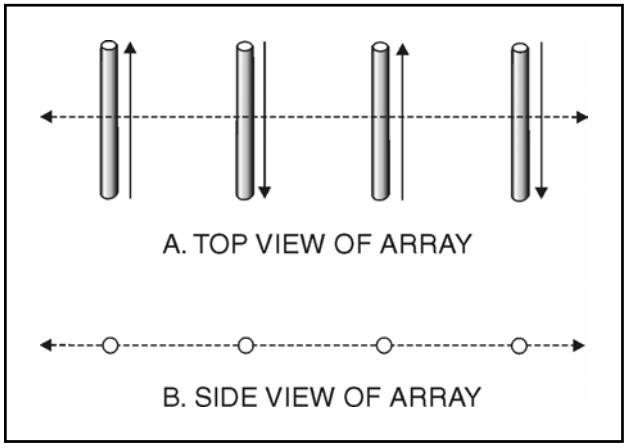

Figure 4-Sum 12. End-Fire Array

Matching stubs are used between elements to maintain current in the proper phase.

The gain of a collinear antenna is greatest when the elements are spaced from 0.4 to 0.5 wavelengths apart or when the number of elements is increased.

The optimum gain of a broadside array is obtained when the elements are spaced 0.65 wavelengths apart.

A parasitic array consists of one or more parasitic elements with a driven element. The amount of power gain and directivity depends on the lengths of the parasitic elements and the spacing between them.

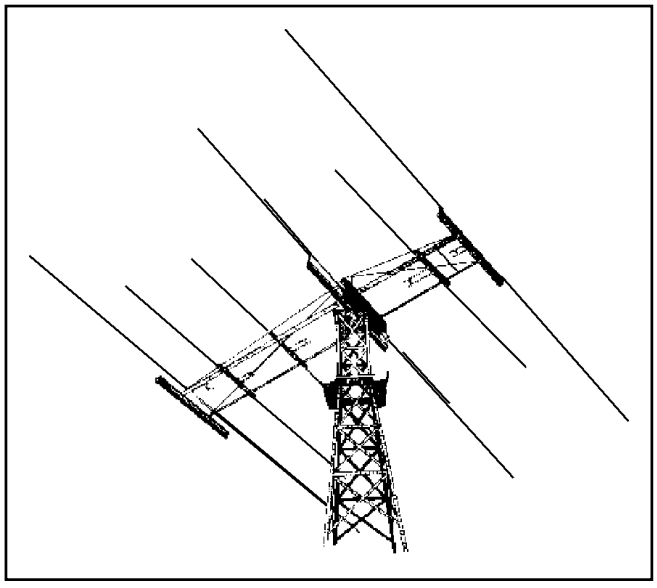

Figure 4-Sum 13. Parasitic Array

Multi-element arrays, such as the yagi, have a narrow frequency response as well as a narrow beam width.

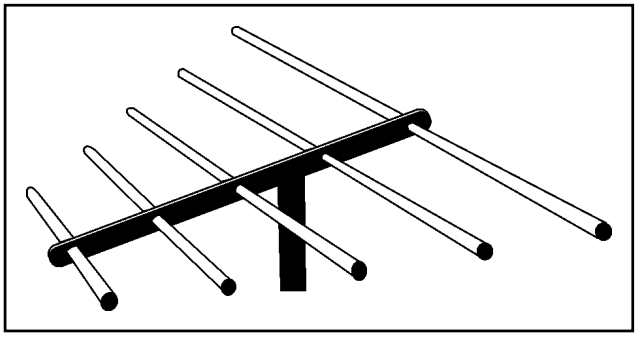

Figure 4-Sum 14. Multi-Element Arrays

A long-wire antenna is an antenna that is a wavelength or more long at the operating frequency. These antennas have directive patterns that are sharp in both the horizontal and vertical planes.

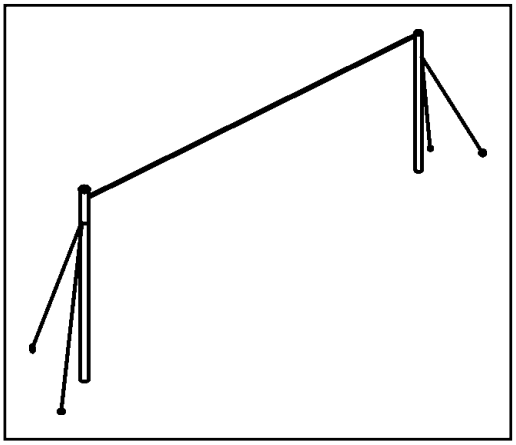

Figure 4-Sum 15. Long-Wire Antenna

Beverage antennas consist of a single wire that is two or more wavelengths long.

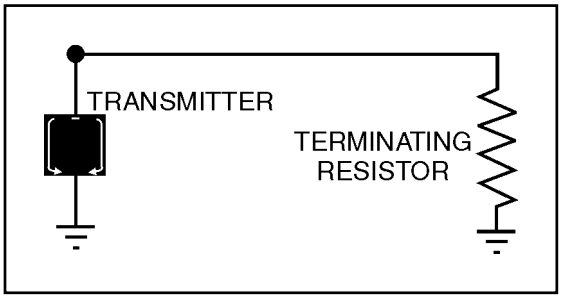

Figure 4-Sum 16. Beverage Antenna Wavelengths

A V antenna is a bidirectional antenna consisting of two horizontal, long wires arranged to form a V.

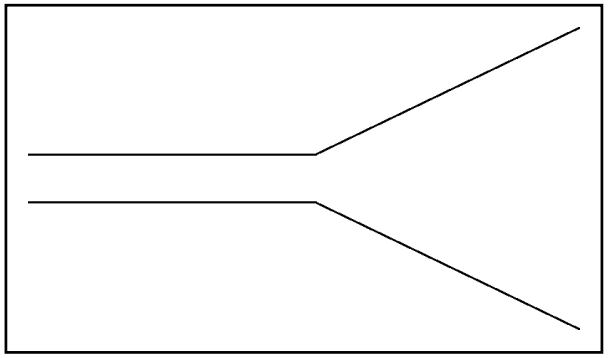

Figure 4-Sum 17. V Antenna Layout

The rhombic antenna uses four conductors joined to form a rhombus shape. This antenna has a wide frequency range, is easy to construct and maintain, and is noncritical as far as operation and adjustment are concerned.

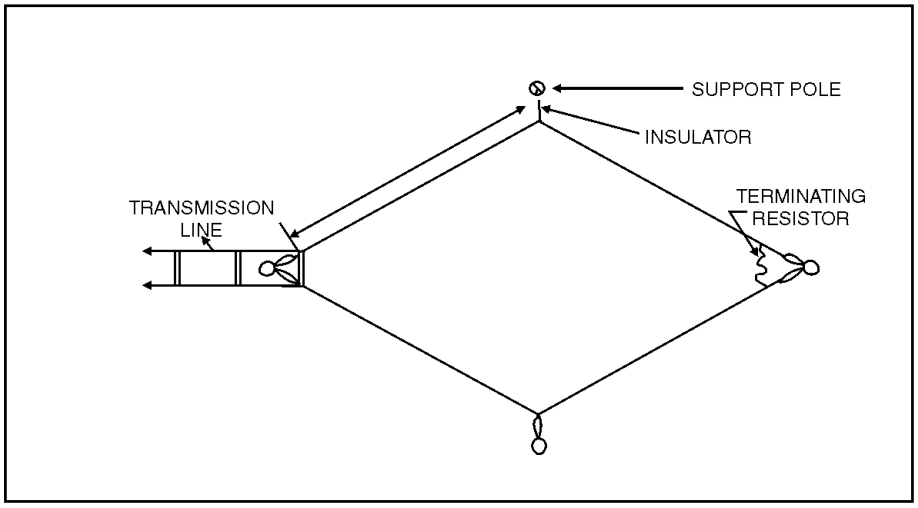

Figure 4-Sum 18. Rhombic Antenna Conductors

The turnstile antenna consists of two horizontal, half-wire antennas mounted at right angles to each other.

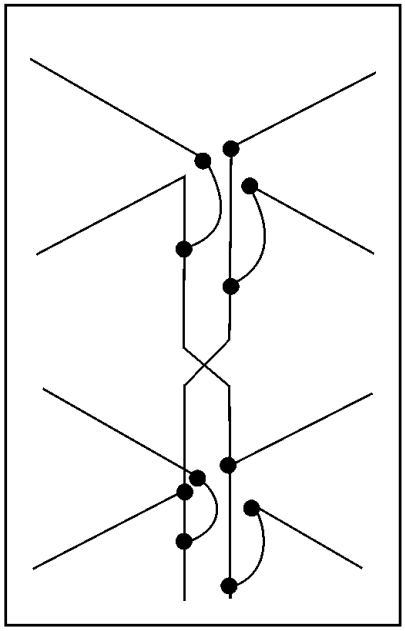

Figure 4-Sum 19. Turnstile Antenna

Check-On-Learning Questions

Antennas

When you are satisfied that you have answered every question to the best of your ability, check your answers using appendix A. If you missed eight or more questions, you should review the chapter, paying particular attention to the areas in which your answers were incorrect.

1. What are the two basic classifications of antennas?
2. What are the three parts of a complete antenna system?
3. What three factors determine the type, size, and shape of an antenna?
4. If a wave travels exactly the length of an antenna from one end to the other and back during the period of 1 cycle, what is the length of the antenna?
5. What are the terms used to identify the points of high current and high voltage on an antenna?
6. What is the term used to identify the points of minimum current and minimum voltage on an antenna?
7. The various properties of a transmitting antenna can apply equally to the same antenna when it is used as a receiving antenna. What term is used for this property?
8. The direction of what field is used to designate the polarization of a wave?
9. If a wave's electric lines of force rotate through 360 degrees with every cycle of RF energy, what is the polarization of this wave?
10. What type of polarization should be used at medium and low frequencies?
11. What is an advantage of using horizontal polarization at high frequencies?
12. What type of polarization should be used if an antenna is mounted on a moving vehicle at frequencies below 50 megahertz?
13. What is the radiation resistance of a half-wave antenna in free space?
14. A radiating source that radiates energy stronger in one direction than another is known as what type of radiator?
15. A radiating source that radiates energy equally in all directions is known as what type of radiator?
16. A flashlight is an example of what type of radiator?
17. What terms are often used to describe basic half-wave antennas?
18. If a basic half-wave antenna is mounted vertically, what type of radiation pattern will be produced?
19. In which plane will the half-wave antenna be operating if it is mounted horizontally?
20. Because the radiation pattern of a dipole is similar to that of a doublet, what will happen to the pattern if the length of the doublet is increased?
21. What is the simplest method of feeding power to the half-wave antenna?
22. What is the radiation pattern of a quarter-wave antenna?
23. Describe the physical arrangement of a ground screen.

24. What is the difference in the amount of impedance between a three-wire dipole and a simple center-fed dipole?
25. Which has a wider frequency range, a simple dipole or a folded dipole?
26. What is the purpose of antenna stubs?
27. What is the primary difference between the major and minor lobes of a radiation pattern?
28. What is the maximum number of elements ordinarily used in a collinear array?
29. Why is the number of elements used in a collinear array limited?
30. How can the frequency range of a collinear array be increased?
31. How is directivity of a collinear array affected when the number of elements is increased?
32. What is the primary cause of broadside arrays losing efficiency when not operating at their designed frequency?
33. When more than two elements are used in a broadside array, how are the elements arranged?
34. As the spacing between elements in a broadside array increases, what is the effect on the major lobes?
35. What are some disadvantages of the end-fire array?
36. Where does the major lobe in the end-fire array occur?
37. To maintain the required balance of phase relationships and critical feeding, how must the end-fire array be constructed?
38. What two factors determine the directivity pattern of the parasitic array?
39. What two main advantages of a parasitic array can be obtained by combining a reflector and a director with the driven element?
40. The parasitic array can be rotated to receive or transmit in different directions. What is the name given to such an antenna?
41. What are the disadvantages of the parasitic array?
42. What is the advantage of adding parasitic elements to a yagi array?
43. The yagi antenna is an example of what type of array?
44. To radiate power efficiently, a long-wire antenna must have what minimum overall length?
45. What is another name for the Beverage antenna?
46. What is the polarity of the currents that feed the V antenna?
47. What is the main disadvantage of the rhombic antenna?
48. What is the primary reason for the development of the turnstile antenna?

Appendix A

Check-On-Learning Answers

CHAPTER 1: WAVE PROPAGATION

1 Propagation means spreading out.

2. A wave is a disturbance that moves through a medium.

3 A means of transferring energy from one place to another.

4. Sound waves, light waves, radio waves, heat waves, water waves.

5. Transverse waves.

6. Radio waves, light waves, and heat waves.

7. A sound wave.

8. A source, medium, and detector (receiver).

9. A sequence of events, such as the positive and negative alternation of electrical current.

10. The space occupied by one cycle of a radio wave at any given instant.

11. The law of reflection states: The angle of incidence is equal to the angle of reflection.

12. When the incident wave is nearly parallel with the surface.

13. When the incident wave is perpendicular to the surface. Also a dull (or black) surface reflects very little regardless of the angle.

14. The density of the two mediums, and the velocity of the waves.

15. The Doppler effect.

16. Sonics.

17. No. The average human ear cannot hear all sounds in the infrasonic and ultrasonic regions.

18. An amplifier.

19. A source, medium, and detector (receiver).

20. Noise and tones.

21. Pitch, intensity, and quality.

22. 20 Hz to 20 kHz.

23. The amount of energy transmitted from a source.

24. Quality.

25. Velocity increases as density decreases and temperature increases.

26. Acoustics.

27. Echo.

28. Reverberation.

29. Resonance.

30. Noise.
31. Mechanical, electrical, and chemical.
32. A photon.
33. Angstrom unit.
34. Red, green and blue.
35. Magenta, yellow and cyan.
36. Reflected or absorbed.
37. None, all colors would be absorbed.
38. Translucent.
39. 186,000 miles per second or 300,000,000 meters per second.
40. Transmitted.
41. Diffused.
42. Light waves, heat waves, and radio waves.
43. The visible spectrum can be seen.
44. Electric field and magnetic field.
45. An antenna.
46. Electric field.
47. Magnetic field.
48. Radiation field.

CHAPTER 2: RADIO WAVE PROPAGATION

1. Induction field and radiation field.
2. Induction field.
3. Radiation field.
4. Fundamental frequency.
5. Harmonic frequency or harmonics.
6. 30 meters.
7. 5 megahertz.
8. Vertically polarized.
9. Direction of wave propagation.
10. Shifting in the phase relationships of the wave.
11. Troposphere, stratosphere, and ionosphere.
12. Stratosphere.
13. Whether the component of the wave is traveling along the surface or over the surface of the earth.
14. Sea water
15. Radio horizon is about one-third farther. .
16. (a) electrical properties of the terrain

    (b) frequency

    (c) polarization of the antenna
17. High energy ultraviolet light waves from the sun.
18 D, E, F1, and F2 layers.
19. D layer is 30 to 55 miles, E layer 55 to 90 miles, and F layers are 90 to 240 miles.
20. Thickness of ionized layer.
21. Critical frequency.
22. (a) density of ionization of the layer

    (b) frequency

    (c) angle at which it enters the layer
23. A zone of silence between the ground wave and sky wave where there is no reception.
24. Where ionization density is greatest.
25. A term used to describe the multiple pattern a radio wave may follow.
26. Selective fading.
27. Natural and man-made interference.
28. Natural.
29. Man-made.

30. (a) filtering and shielding of the transmitter

    (b) limiting bandwidth

    (c) cutting the antenna to the correct frequency

31. (a) physical separation of the antenna

    (b) limiting bandwidth of the antenna

    (c) use of directional antennas

32. Regular and irregular variations.

33. Regular variations can be predicted but irregular variations are unpredictable.

34. Daily, seasonal, 11-year, and 27-day variations.

35. Sporadic E, sudden disturbances, and ionospheric storms.

36. MUF is maximum usable frequency. LUF is lowest usable frequency. FOT is commonly known as optimum working frequency.

37. MUF is highest around noon. Ultraviolet light waves from the sun are most intense.

38. When LUF is too low it is absorbed and is too weak for reception.

39. Signal-to-noise ratio is low and the probability of multipath propagation is greater.

40. Frequent signal fading and dropouts.

41. FOT is the most practical operating frequency that can be relied on to avoid problems of multipath, absorption, and noise.

42. They can cause attenuation by scattering.

43. It can cause attenuation by absorption.

44. It is a condition where layers of warm air are formed above layers of cool air.

45. It can cause VHF and UHF transmission to be propagated far beyond normal line-of-sight distances.

46. Troposphere.

47. VHF and above.

48. Near the mid-point between the transmitting and receiving antennas, just above the radio horizon.

CHAPTER 3: PRINCIPLES OF TRANSMISSION LINES

1. Transmission line.
2. Input end, generator end, transmitter end, sending end, and source.
3. Output end, receiving end, load end and sink.
4. Parallel two-wire, twisted pair, shielded pair and coaxial line.
5. Power lines, rural telephone lines, and telegraph lines.
6. High radiation losses and noise pickup.
7. Twin lead.
8. The conductors are balanced to ground.
9. Air coaxial (rigid) and solid coaxial (flexible).
10. The ability to minimize radiation losses.
11. Expensive to construct, must be kept dry, and high frequency losses limit the practical length of the line.
12. Cylindrical and rectangular.
13. Copper, dielectric, and radiation.
14. Copper losses.
15. Dielectric losses.
16. λ = 20 meters.
17. (1) Type of line used, (2) dielectric in the line, and (3) length of line.
18. Inductance is expressed in microhenrys per unit length, capacitance is expressed in picofarads per unit length, and resistance is expressed in ohms per unit length.
19. The small amount of current that flows through the dielectric between two wires of a transmission line and is expressed in micromhos per unit length.
20. When the characteristic impedance of the transmission line and the load impedance are equal.
21. Z_0 and it is the ratio of E to I at every point along the line.
22. Between 50 and 600 ohms.
23. Incident waves from generator to load. Reflected waves from load back to generator.
24. 2 and 6 have zero resultant wave and they indicate that the incident and reflected waves are 180 degrees out of phase at all parts.
25. One-fourth the distance from each end of the line.
26. The load impedance of such a line is equal to Z_0.
27. Even quarter-wave points (1/2λ, l, 3/2λ, etc.).
28. At 1/2 wavelength from the end and at every 1/2 wavelength along the line.
29. Power standing-wave ratio (PSWR).
30. The existence of voltage variations on a line.

CHAPTER 4: ANTENNAS

1. Half-wave (Hertz) and quarter-wave (Marconi).
2. Coupling device, feeder, and antenna.
3. Frequency of operation of the transmitter, amount of power to be radiated, and general direction of the receiving set.
4. One-half the wavelength.
5. Current and voltage loops.
6. Current and voltage nodes.
7. Reciprocity of antennas.
8. Electric (E) field.
9. Circular polarization.
10. Vertical polarization.
11. Less interference is experienced by man-made noise sources.
12. Vertical polarization.
13. 73 ohms.
14. Anisotropic radiator.
15. Isotropic radiator.
16. Anisotropic radiator.
17. Dipole, doublet and Hertz.
18. Nondirectional.
19. Vertical plane.
20. The pattern would flatten.
21. To connect one end through a capacitor to the final output stage of the transmitter.
22 .A circular radiation pattern in the horizontal plane, or same as a half wave.
23. It is composed of a series of conductors arranged in a radial pattern and buried 1 to 2 feet below the ground.
24. Nine times the feed-point impedance.
25. Folded dipole.
26. To produce desired phase relationship between connected elements.
27. Major lobes have the greatest amount of radiation.
28. Four.
29. As more elements are added, an unbalanced condition in the system occurs which impairs efficiency.
30. By increasing the lengths of the elements of the array.
31. Directivity increases.

32. Lower radiation resistance.
33. Parallel and in the same plane.
34. They sharpen.
35. Extremely low radiation resistance, confined to one frequency, and affected by atmospheric conditions.
36. Along the major axis
37. Symmetrically.
38. Length of the parasitic element (tuning) and spacing between the parasitic and driven elements.
39. Increased gain and directivity.
40. Rotary array.
41. Their adjustment is critical and they do not operate over a wide frequency range.
42. Increased gain.
43. Multi-element parasitic array.
44. One-half wavelength.
45. Wave antenna.
46. Opposite.
47. It requires a large antenna site.
48. For omnidirectional VHF communications.

Glossary

absorption	(1) Absorbing light waves. Does not allow any reflection or refraction. (2) Atmospheric absorption of RF energy with no reflection or refraction (adversely affects long distance communications).
acoustics	The science of sound.
alternating current (AC)	An electrical current, which constantly changes amplitude and polarity at regular intervals.
amplitude	The portion of a cycle measured from a reference line to a maximum value above (or to a maximum value below) the line.
angle of incidence	The angle between the incident wave and the normal.
angle of reflection	The angle between the reflected wave and the normal.
angle of refraction	The angle between the normal and the path of a wave through the second medium.
angstrom unit	The unit used to define the wavelength of light waves.
anisotropic	The property of a radiator to emit strong radiation in one direction.
antenna	A conductor or set of conductors used either to radiate RF energy into space or to collect RF energy from space.
AR	Army regulation
array of arrays	Same as COMBINATION ARRAY.
bay	Part of an antenna array.
beverage antenna	A horizontal, longwire antenna designed for reception and transmission of low-frequency, vertically polarized ground waves.
bidirectional array	An array that radiates in opposite directions along the line of maximum radiation.
broadside array	An array in which the direction of maximum radiation is perpendicular to the plane containing the elements.

center-feed method	Connecting the center of an antenna to a transmission line, which is then connected to the final (output) stage of the transmitter.
characteristic impedance	The ratio of voltage to current at any given point on a transmission line. Represented by a value of impedance.
coaxial line	A type of transmission line that contains two concentric conductors.
collinear array	An array with all the elements in a straight line. Maximum radiation is perpendicular to the axis of the elements.
combination array	An array system that uses the characteristics of more than one array.
complementary (secondary) colors of light	The colors of light produced when two of the primaries are mixed in overlapping beams of light. The complementary colors of light are magenta, yellow, and cyan.
complex wave	A wave produced by combining two or more pure tones at the same time.
compression waves	Longitudinal waves that have been compressed (made more dense) as they move away from the source.
conductance	The opposite of resistance in transmission lines. The minute amount of resistance that is present in the insulator of a transmission line.
connected array	Another term for DRIVEN ARRAY.
copper losses	The I^2R loss in a conductor caused by the current flow through the resistance of the conductor.
corner-reflector antenna	A half-wave antenna with a reflector consisting of two flat metal surfaces meeting at an angle behind the radiator.
counterpoise	A network of wire that is connected to a quarter-wave antenna at one end and provides the equivalent of an additional one-quarter wavelength.
coupling device	A coupling coil that connects the transmitter to the feeder.
crest (top)	The peak of the positive alternation (maximum value above the line) of a wave.

critical angle	The maximum angle at which radio waves can be transmitted and still be refracted back to earth.
critical frequency	The maximum frequency at which a radio wave can be transmitted vertically and still be refracted back to earth.
current-feed method	Same as CENTER-FEED METHOD.
current standing-wave ratio (ISWR)	The ratio of maximum to minimum current along a transmission line.
cycle	One complete alternation of a sine wave that has a maximum value above and a maximum value below the reference line.
damping	Reduction of energy by absorption.
density	(1) The compactness of a substance. (2) Mass per unit volume.
detector	The device that responds to a wave or disturbance.
dielectric heating	The heating of an insulating material by placing it in a high frequency electric field.
dielectric losses	The losses resulting from the heating effect on the dielectric material between conductors.
diffraction	The bending of the paths of waves when the waves meet some form of obstruction.
diffusion	The scattering of reflected light waves (beams) from an object, such as white paper.
dipole	A common type of half-wave antenna made from a straight piece of wire cut in half. Each half operates at a quarter wavelength of the output.
direct current (DC)	An electric current that flows in one direction.
directional	Radiation that varies with direction.
director	The parasitic element of an array that reinforces energy coming from the driver toward itself.
directivity	The property of an array that causes more radiation to take place in certain directions than in others.
dispersion	The refraction of light waves that causes the different frequencies to bend at slightly different angles.

distributed constants	The constants of inductance, capacitance, and resistance in a transmission line. The constants are spread along the entire length of the line and cannot be distinguished separately.
Doppler effect	The apparent change in frequency or pitch when a sound source moves either toward or away from a listener.
doublet	Another name for the dipole antenna.
driven array	An array in which all of the elements are driven.
driven element	An element of an antenna (transmitting or receiving) that is connected directly to the transmission line.
echo	The reflection of the original sound wave as it bounces off a distant surface.
elasticity	The ability of a substance to return to its original state.
electromagnetic field	The combination of an electric (E) field and a magnetic (H) field.
electromagnetic interference	Man-made or natural interference that degrades the quality of reception of radio waves.
electromagnetic radiation	The radiation of radio waves into space.
electric (E) field	The field produced as a result of a voltage charge on a conductor or antenna.
electromagnetic interference (EMI)	Any electromagnetic disturbance that interrupts, obstructs, or otherwise degrades or limits the effective performance of electronics/electrical equipment.
electromotive force (EMF)	Electromotive force or voltage is electrical pressure that can force the free electrons to move in the direction of negative to positive.
element	A part of an antenna that can be either an active radiator or a parasitic radiator.
end-feed method	Connecting one end of an antenna through a capacitor to the final output stage of a transmitter.
end-fire array	An array in which the direction of radiation is parallel to the axis of the array.
fading	Variations in signal strength by atmospheric conditions.

feeder	A transmission line that carries energy to the antenna.
flat line	A transmission line that has no standing waves. This line requires no special tuning device to transfer maximum power.
flexible coaxial line	A coaxial line made with a flexible inner conductor insulated from the outer conductor by a solid, continuous insulating material.
FM	field manual
folded dipole	An ordinary half-wave antenna (dipole) that has one or more additional conductors connected across the ends parallel to each other.
four-element array	An array with three parasitic elements and one driven element.
free-space loss	The loss of energy of a radio wave because of the spreading of the wavefront as it travels from the transmitter.
frequency	The number of cycles that occur in one second. Usually expressed in hertz.
frequency diversity	Transmitting (and receiving) of radio waves on two different frequencies simultaneously.
frequency modulation (FM)	Frequency modulation is a method of impressing data onto an alternating-current wave by varying the instantaneous frequency of the wave. This scheme can be used with analog or digital data.
front-to-back ratio	The ratio of the energy radiated in the principal direction to the energy radiated in the opposite direction.
fundamental frequency	The basic frequency or first harmonic frequency.
gain	The ratio between the amount of energy propagated from an antenna that is directional to the energy from the same antenna that would be propagated if the antenna were not directional.
generator end	See INPUT END.
ground plane	The portion of a ground plane antenna that acts as ground.

ground-plane antenna	A type of antenna that uses a ground plane as a simulated ground to produce low-angle radiation.
ground reflection loss	The loss of RF energy each time a radio wave is reflected from the earth's surface.
ground screen	A series of conductors buried below the surface of the earth and arranged in a radial pattern. Used to reduce losses in the ground.
ground waves	Radio waves that travel near the surface of the earth.
half-wave dipole antenna	An antenna, consisting of two rods (one-quarter wavelength each) in a straight line, that radiates electromagnetic energy.
harmonic	A frequency that is a whole number multiple of a smaller base frequency.
Hertz antenna	A half-wave antenna installed some distance above ground and positioned either vertically or horizontally.
high frequency (HF)	The range of the radio frequency spectrum extending from 3 MHz to 30 MHz.
horizontal axis	On a graph, the straight line axis plotted from left to right.
horizontal pattern	The part of a radiation pattern that is radiated in all directions along the horizontal plane.
horizontally polarized	Waves that are radiated with their E field component parallel to the earth's surface.
incident wave	(1) The wave that strikes the surface of a medium. (2) The wave that travels from the sending end to the receiving end of a transmission line.
induction field	The electromagnetic field produced about an antenna when current and voltage are present on the same antenna.
induction losses	The losses that occur when the electromagnetic field around a conductor cuts through a nearby metallic object and induces a current into that object.
infrasonic (subsonic)	Sounds below 15 hertz.
input end	The end of a two-wire transmission line that is connected to a source.

input impedance	The impedance presented to the transmitter by the transmission line and its load.
intensity (of sound)	The measurement of the amplitude of sound energy. Sometimes mistakenly called loudness.
interecept	The point where two lines drawn on a graph cross each other.
interference	Any disturbance that produces an undesirable response or degrades a wave.
ionosphere	The most important region of the atmosphere extending from 31 miles to 250 miles above the earth. Contains four cloud-like layers that affect radio waves.
ionospheric storms	Disturbances in the earth's magnetic field that make communications practical only at lower frequencies.
ionization	The process of upsetting electrical neutrality.
isotropic radiation	The radiation of energy equally in all directions.
leakage current	The small amount of current that flows between the conductors of a transmission line through the dielectric.
light rays	Straight lines that represent light waves emitting from a source.
load end	See OUTPUT END.
loading	See LUMPED-IMPEDANCE TUNING.
lobe	An area of a radiation pattern plotted on a polar-coordinate graph that represents maximum radiation.
long-wire antenna	An antenna that is a wavelength or more long at its operating frequency.
longitudinal waves	Waves in which the disturbance (back and forth motion) takes place in the direction of propagation. Sometimes called compression waves.
loop	The curves of a standing wave or antenna that represent amplitude of current or voltage.
low frequency (LF)	The range of the radio frequency spectrum extending from 30 kHz to 300 kHz.
lowest usable frequency (luf)	The minimum operating frequency that can be used for communications between two points.

lumped constants	The properties of inductance, capacitance, and resistance in a transmission line.
lumped-impedance tuning	The insertion of an inductor or capacitor in series with an antenna to lengthen or shorten the antenna electrically.
magnetic (H) field	The field produced when current flows through a conductor or antenna.
major lobe	The lobe in which the greatest amount of radiation occurs.
Marconi antenna	A quarter-wave antenna oriented perpendicular to the earth and operated with one end grounded.
maximum usable frequency (muf)	Maximum frequency that can be used for communications between two locations for a given time of day and a given angle of incidence.
medium	The substance through which a wave travels from one point to the next. Air, water, and wood are examples of a medium.
medium frequency (MF)	The range of the radio frequency spectrum extending from 300 kHz to 3 MHz.
minor lobe	The lobe in which the radiation intensity is less than a major lobe.
multielement array	An array consisting of one or more arrays and classified as to directivity.
multielement parasitic array	An array that contains two or more parasitic elements and a driven element.
multipath	The multiple paths a radio wave may follow between transmitter and receiver.
natural horizon	The line-of-sight horizon.
negative alternation	The portion of a sine wave below the reference line.
node	The fixed minimum points of voltage or current on a standing wave or antenna.
noise (of sound)	An unwanted disturbance caused by spurious waves that originate from man-made or natural sources.
nondirectional	See OMNIDIRECTIONAL.

nonluminous bodies	Objects that either reflect or diffuse light that falls upon them.
nonresonant line	A transmission line that has no standing waves of current or voltage.
normal	The imaginary line perpendicular to the point at which the incident wave strikes the reflecting surface. Also called the perpendicular.
null	On a polar-coordinate graph, the area that represents minimum or 0 radiation.
omnidirectional	Transmitting in all directions.
opaque	A type of substance that does not transmit any light rays.
open-ended line	A transmission line that has an infinitely large terminating impedance.
optimum working frequency (fot)	The most practical operating frequency that can be used with the least amount of problems; roughly 85 percent of the maximum usable frequency.
origin	The point on a graph where the vertical and horizontal axes cross each other.
output end	The end of a transmission line that is opposite the source.
output impedance	The impedance presented to the load by the transmission line and its source.
parallel resonant circuit	A circuit that acts as a high impedance at resonance.
parallel-wire	A type of transmission line consisting of two parallel wires.
parasitic array	An array that has one or more parasitic elements.
parasitic element	The passive element of an antenna array that is connected to neither the transmission line nor the driven element.
period	The amount of time required for completion of one full cycle.
pitch	A term used to describe the frequency of a sound heard by the human ear.

plane of polarization	The plane (vertical or horizontal) with respect to the earth in which the E field propagates.
point of zero displacement	See REFERENCE LINE.
polar-coordinate graph	A graph whose axes consist of a series of circles with a common center and a rotating radius extending from the center of the concentric circles.
positive alternation	The portion of a sine wave above the reference line.
power loss	The heat loss in a conductor as current flows through it.
power standing-wave ratio (PSWR)	The ratio of the square of the maximum and minimum voltages of a transmission line.
primary colors (of light)	The three primary colors of light (red, green, and blue), from which all other colors may be derived.
prism	A triangular-shaped glass that refracts and disperses light waves into component wavelengths.
propagation	Waves traveling through a medium.
quality (of sound)	The factor that distinguishes tones of pitch and loudness.
quarter-wave antenna	Same as the Marconi antenna.
radiation field	The electromagnetic field that detaches itself from an antenna and travels through space.
radiation losses	The losses that occur when magnetic lines of force about a conductor are projected into space as radiation and are not returned to the conductor as the cycle alternates.
radiation pattern	A plot of the radiated energy from an antenna.
radiation resistance	The resistance, which if inserted in place of an antenna, would consume the same amount of power as that radiated by the antenna.
radio frequencies (RF)	Electromagnetic frequencies that fall between 3 kilohertz and 300 gigahertz and are used for radio communications.

radio horizon	The boundary beyond the natural horizon in which radio waves cannot be propagated over the earth's surface.
radio wave	(1) A form of radiant energy that can neither be seen nor felt. (2) An electromagnetic wave generated by a transmitter.
rarefied wave	A longitudinal wave that has been expanded or rarefied (made less dense) as it moves away from the source.
receiver	The object that responds to a wave or disturbance. Same as detector.
receiving antenna	The device used to pick up an RF signal from space.
receiving end	See OUTPUT END.
reciprocity	The property of interchangeability of the same antenna for transmitting and receiving.
rectangular-coordinate graph	A graph in which straight-line axes (horizontal and vertical) are perpendicular.
reference line	The position a particle of matter would occupy if it were not disturbed by wave motion.
reflected wave	(1) The wave that reflects back from a medium. (2) Waves traveling from the load back to the generator on a transmission line. (3) The wave moving back to the sending end of a transmission line after reflection has occurred.
reflection waves	Waves that are neither transmitted nor absorbed, but are reflected from the surface of the medium they encounter.
reflector	The parasitic element of an array that causes maximum energy radiation in a direction toward the driven element.
refraction	The changing of direction as a wave leaves one medium and enters another medium of a different density.
reradiation	The reception and retransmission of radio waves caused by turbulence in the troposphere.
resonance	The condition produced when the frequency of vibrations are the same as the natural frequency (of a cavity). The vibrations reinforce each other.

resonant line	A transmission line that has standing waves of current and voltage.
rest position	See REFERENCE LINE.
reverberation	The multiple reflections of sound waves.
rhombic antenna	frequency transmission and reception.
rigid coaxial line	A coaxial line consisting of a central, insulated wire (inner conductor) mounted inside a tubular outer conductor.
scatter angle	The angle at which the receiving antenna must be aimed to capture the scattered energy of tropospheric scatter.
self-induction	The phenomenon caused by the expanding and collapsing fields of an electron which encircles other electrons and retards the movement of the encircled electrons.
self-luminous bodies	Objects that produce their own light.
sending end	See INPUT END.
series resonant circuit	A circuit that acts as a low impedance at resonance.
shielded pair	A line consisting of parallel conductors separated from each other and surrounded by a solid dielectric.
short-circuited line	A transmission line that has a terminating impedance equal to 0.
sink	See OUTPUT END.
skin effect	Skin effect is a tendency for alternating current to flow mostly near the outer surface of a solid electrical conductor, such as metal wire, at frequencies above the audio range. .
skip distance	The distance from a transmitter to the point where the sky wave is first returned to earth.
skip zone	A zone of silence between the point where the ground wave becomes too weak for reception and the point where the sky wave is first returned to earth.
sky waves	Radio waves reflected back to earth from the ionosphere.

sonic	Pertaining to sounds capable of being heard by the human ear.
source	(1) The object that produces waves or disturbance. (2) The name given to the end of a two-wire transmission line that is connected to a source.
space diversity	Reception of radio waves by two or more antennas spaced some distance apart.
space wave	A radio wave that travels directly from the transmitter to the receiver and remains in the troposphere.
spectrum	(1) The entire range of electromagnetic waves. (2) VISIBLE. The range of electromagnetic waves that stimulate the sense of sight. (3) ELECTROMAGNETIC. The entire range of electromagnetic waves arranged in order of their frequencies.
sporadic E layer	Irregular cloud-like patches of unusually high ionization. Often forms at heights near the normal E layer.
spreader	Insulator used with transmission lines and antennas to keep the parallel wires separated.
standing wave	The distribution of voltage and current formed by the incident and reflected waves which have minimum and maximum points on a resultant wave that appears to stand still.
standing-wave ratio (SWR)	The ratio of the maximum (voltage, current) to the minimum (voltage, current) of a transmission line. Measures the perfection of the termination of the line.
stratosphere	Located between the troposphere and the ionosphere. Has little effect on radio waves.
stub	Short section of a transmission line used to match the impedance of a transmission line to an antenna. Can also be used to produce desired phase relationships between connected elements of an antenna.
sudden ionospheric disturbance (sid)	An irregular ionospheric disturbance that can totally blank out HF radio communications.
supersonic	Speed greater than the speed of sound.
surface wave	A radio wave that travels along the contours of the earth, thereby being highly attenuated.

TC	training circular
temperature inversion	The condition in which warm air is formed above a layer of cool air that is near the earth's surface.
three-element array	An array with two parasitic elements (reflector and director) and a driven element.
TM	technical manual
tones	Musical sounds.
translucent	A type of substance, such as frosted glass, through which some light rays can pass but through which objects cannot be seen clearly.
transmission line	A device designed to guide electrical energy from one point to another.
transmitting antenna	The device used to send the transmitted signal energy into space.
transparent	A type of substance, such as glass, that transmits almost all of the light waves that fall upon it.
transmission mediums	The various types of lines and waveguides used as transmission lines.
transmitter end	See INPUT END.
transverse wave motion	The up and down motion of a wave as the wave moves outward.
troposphere	The portion of the atmosphere closest to the earth's surface, where all weather phenomena take place.
tropospheric scatter	The propagation of radio waves in the troposphere by means of scatter.
trough (bottom)	The peak of the negative alternation (maximum value below the line).
tuned line	Another name for the resonant line. This line uses tuning devices to eliminate the reactance and to transfer maximum power from the source to the line.
turnstile antenna	A type of antenna used in VHF communications that is omnidirectional and consists of two horizontal half-wave antennas mounted at right angles to each other in the same horizontal plane.

twisted pair	A line consisting of two insulated wires twisted together to form a flexible line without the use of spacers.
two-wire open line	A parallel line consisting of two wires that are generally spaced from 2 to 6 inches apart by insulating spacers.
two-wire ribbon (twin lead)	A parallel line similar to a two-wire open line except that uniform spacing is assured by embedding the two-wires in a low-loss dielectric.
ultrahigh frequency (UHF)	The range of the radio frequency spectrum extending from 30 MHz to 3 GHz.
ultrasonic	Sounds above 20,000 hertz.
unidirectional array	An array that radiates in only one general direction.
untuned line	Another name for the flat or nonresonant line.
V antenna	A bidirectional antenna, shaped like a V, which is widely used for communications.
velocity	The rate at which a disturbance travels through a medium.
vertical axis	On a graph, the straight-line axis oriented from bottom to top.
vertical pattern	The part of a radiation pattern that is radiated in the vertical plane.
vertically polarized	Waves radiated with the E field component perpendicular to the earth's surface.
very high frequency (VHF)	The range of the radio frequency spectrum extending from 30 MHz to 300 MHz.
voltage-feed method	Same as END FEED METHOD.
voltage standing-wave ratio (VSWR)	The ratio of maximum to minimum voltage of a transmission line.
wave antenna	Same as BEVERAGE ANTENNA.
wave motion	A recurring disturbance advancing through space with or without the use of a physical medium.
wave train	A continuous series of waves with the same amplitude and wavelength.

wavefront	A small section of an expanding sphere of electromagnetic radiation, perpendicular to the direction of travel of the energy.
waveguide	A hollow metal tube used as a transmission line to guide energy from one point to another.
wavelength	(1) The distance in space occupied by 1 cycle of a radio wave at any given instant. (2) The distance a disturbance travels during one period of vibration.
yagi antenna	A multi-element parasitic array. Elements lie in the same plane as those of the end-fire array.

FOREWORD

Communications and information systems (CIS) support collecting, processing, and exchanging information. CIS automate routine functions, freeing commanders and staffs to focus on the aspects of command and control that require experience, judgment, and intuition. Personnel who install, operate, and maintain CIS play a key role in the command and control of the Marine air-ground task force (MAGTF). It is an understatement to say that the success of the MAGTF in the modern battlespace depends on the effective employment of CIS.

One of the most important networks of the MAGTF CIS architecture is single-channel radio (SCR). SCR is the principal means of communications support for maneuver units. SCR communications equipment is easy to operate, and networks are easily established, rapidly reconfigured, and, most importantly, easily maintained on the move. SCR provides secure voice communication and supports limited data information exchange. MAGTF SCR equipment is fielded in many configurations and includes hand-held, manpack, vehicle-mounted, bench-mounted, and sheltered radios. These radios operate in simplex and half-duplex modes. The most widely employed tactical radios provide integrated communications security (COMSEC) and jam resistance through frequency hopping.

Tactical SCRs operate in the three military radio frequency bands (high frequency [HF], very high frequency [VHF], and ultrahigh frequency [UHF]). In the HF band, SCR can support long-range communications, albeit at the expense of mobility. SCR in the VHF and UHF bands is normally limited to line of sight. SCR satellite communications (SATCOM) provide mobility, flexibility, and ease of operation with unlimited range. Limitations of SCR include susceptibility to enemy electronic warfare; cosite, footprint, terrain, and atmospheric interference; the requirement for close coordination and detailed planning; a need for common timing, frequency, and equipment; and limited spectrum availability. The latter is particularly critical for SATCOM.

Of all the variables affecting single-channel radio communications, the one factor that an operator has the most control over is the antenna. With the right antenna, an operator can change a marginal net into a reliable net. Marine Corps Reference Publication (MCRP) 6-22D, *Antenna Handbook*, gives operators the knowledge to properly select and employ antennas to provide the strongest possible signal at the receiving station of the circuit.

MCRP 6-22D builds on the doctrinal foundation established in Marine Corps Warfighting Publication (MCWP) 6-22, *Communications and Information Systems*. This handbook is intended not only for CIS officers and radio operators, but for all personnel desiring information about antenna fundamentals.

MCRP 6-22D supersedes Fleet Marine Force Reference Publication (FMFRP) 3-34, *Field Antenna Handbook*, dated 5 March 1991.

Reviewed and approved this date.

BY DIRECTION OF THE COMMANDANT OF THE MARINE CORPS

J. E. RHODES
Lieutenant General, U.S. Marine Corps
Commanding General
Marine Corps Combat Development Command

Chapter 1

Radio Principles

ELECTROMAGNETIC RADIATION

Electromagnetic radiation includes radio waves, microwaves, infrared radiation, visible light, ultraviolet waves, X-rays, and gamma rays. Together they make up the electromagnetic spectrum. They all move at the speed of light (186,000 miles/300 million meters per second). The only difference between them is their wavelength (the distance a wave travels during one complete cycle [vibration]), which is directly related to the amount of energy the waves carry. The shorter the wavelength, the higher the energy. Figure 1-1 lists the electromagnetic spectrum components according to wavelength and frequency (the number of complete cycles [vibrations] per second). A portion of the spectrum which is used for HF, VHF, and UHF radio communication has been expanded to show more detail.

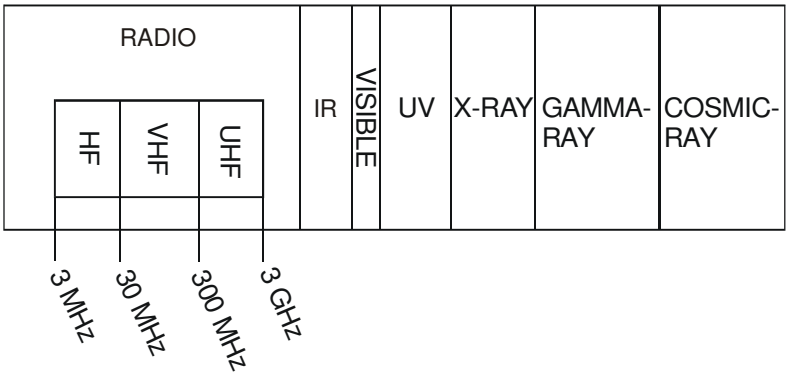

Figure 1-1. Electromagnetic Spectrum.

RADIO WAVES

Radio waves propagate (travel) much like surface water waves. They travel near the Earth's surface and also radiate skyward at various angles to the Earth's surface. As the radio waves travel, their energy spreads over an ever-increasing surface area. A typical radio wave has two components, a crest (top portion) and a trough (bottom portion). These components travel outward from the transmitter, one after the other, at a consistent velocity (speed). The distance between successive wave crests is called a wavelength and is commonly represented by the Greek lowercase lambda (λ) (see fig. 1-2).

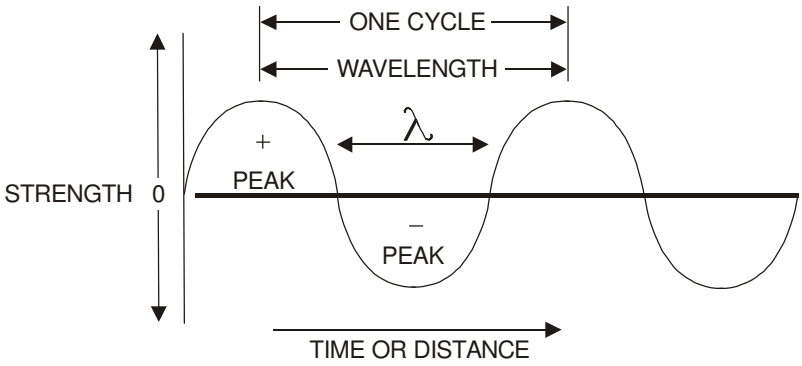

Figure 1-2. Radio Wave.

Frequency

Radio waves transmit radio and television (TV) signals. They have wavelengths that range from less than a centimeter to tens or even hundreds of meters. Frequency modulated (FM) radio waves are shorter than amplitude modulated (AM) radio waves. A radio wave's frequency equals the number of complete cycles that occur in 1 second. The longer the cycle time, the longer the wavelength

and the lower the frequency. The shorter the cycle time, the shorter the wavelength and the higher the frequency.

Frequency is measured and stated in hertz (Hz). A radio wave frequency is very high. It is generally measured and stated in thousands of hertz (kilohertz [kHz]), in millions of hertz (megahertz [MHz]), or sometimes in billions of hertz (gigahertz [GHz]).

1 Hz	=	1 cycle per second
1 kHz	=	1 thousand cycles per second
1 MHz	=	1 million cycles per seconds
1 GHz	=	1 billion cycles per second

Frequency Calculation

For practical purposes, the velocity of a radio wave is considered to be constant, regardless of the frequency or the amplitude of the transmitted wave. To find the frequency when the wavelength is known, divide the velocity by the wavelength.

$$\text{Frequency (hertz)} = \frac{\text{300,000,000 (meters per second)}}{\text{Wavelength (meters)}}$$

To find the wavelength when the frequency is known, divide the velocity by the frequency.

$$\text{Wavelength (meters)} = \frac{\text{300,000,000 (meters per second)}}{\text{Frequency (hertz)}}$$

Frequency Bands

Frequency spectrum designations are—

HF	VHF	UHF
3 to 30 MHz	30 to 300 MHz	300 to 3,000 MHz/3GHz

HF is used primarily for long-range communications. An HF signal is reflected by the outermost portion of the atmosphere, the ionosphere. VHF is used for short-range communications. To use VHF, it is necessary to be able to visualize a direct line of sight (LOS) between the transmitter and receiver. This limits UHF to distances that are not much greater than the distance to the horizon, assuming that there are no massive obstructions in the LOS. When the LOS path exists and VHF transmission is possible, VHF is always preferred to HF because a VHF signal can be made to follow a much narrower and more direct path to the receiver. UHF is a third type of transmission. UHF transmission is like VHF in that both follow the direct or LOS path. But with the proper antenna, UHF transmission can be made to follow an even narrower path to the receiver than VHF.

Each frequency band has unique characteristics. The ranges and power requirements shown in table 1-1 are for normal operating conditions (i.e., proper siting and antenna orientation and correct operating procedures). Ranges will change according to the condition of the propagation medium and the transmitter output power.

Table 1-1. Frequency Range Characteristics.

Band	Ground Wave Range	Sky Wave Range	Power Required
HF	0–50 miles	100–8000 miles	.5–5 kW
VHF	0–30 miles	50–150 miles	.5 or less kW
UHF	0–50 miles	N/A	.5 or less kW

Tactical SCRs operate in the three military radio frequency bands shown in table 1-2.

Table 1-2. Ground SCRs.

Frequency Band	MAGTF SCR Equipment Used	Operating Frequency Range	Typical Application
HF	AN/PRC-104 AN/GRC-193 AN/MRC-138	2–29.999 MHz	Radio LOS and beyond/long range
VHF	AN/PRC-68 AN/PRC-119 AN/VRC-88 (A, D) AN/VRC-89 (A, D) AN/VRC-90 (A, D) AN/VRC-91 (A, D) AN/VRC-92 (A, D) AN/GRC-213 AN/MRC-145	30–88 MHz	Radio LOS and relay/retransmission
	AN/PRC-113 AN/VRC-83	116–150 MHz	Critical LOS (ground to air)
UHF	AN/PRC-113 AN/VRC-83 AN/GRC-171	225–400 MHz	Critical LOS (ground to air)
	AN/PSC-3 AN/PSC-5		SATCOM footprint

RADIO COMMUNICATION CIRCUIT

The radio equipment for communicating between two stations, including the path the radio signal follows through the air, is a radio link. A radio link consists of seven components: transmitter, power supply, transmission lines, transmitting antenna, propagation path, receiving antenna, and receiver.

The transmitter generates a radio signal. The power supply provides power for the operating voltage of the radio (battery or generator). The transmission line delivers the signal from the transmitter to the transmitting antenna. The transmitting antenna sends the radio signal into space toward the receiving antenna. The path in space that the radio signal follows as it goes to the receiving antenna is the propagation path. The receiving antenna intercepts or receives the signal and sends it through a transmission line to the receiver. The receiver processes the radio signal so it can be heard (fig 1-3).

The radio operator's objective is to provide the strongest possible signal to the receiving station. The best possible signal is one that provides the greatest signal-to-noise (S/N) ratio at the receiving antenna.

To implement a radio communications circuit it is necessary to—

- Generate and radiate an electromagnetic wave modulated with information (e.g., voice, Morse code).
- Make the wave propagate efficiently from the transmitting antenna to the receiving antenna.
- Intercept the wave by using a receiving antenna.
- Demodulate the energy so that the information originally transmitted becomes available in a useful form.

Choosing the right antenna and matching its characteristics to the best propagation path are the two most important factors in setting up a communications circuit. The weakest link in the communications circuit is the wrong propagation path. The best transmitter, antenna, and receiver are of little use if the frequency is wrong or the propagation path is improper.

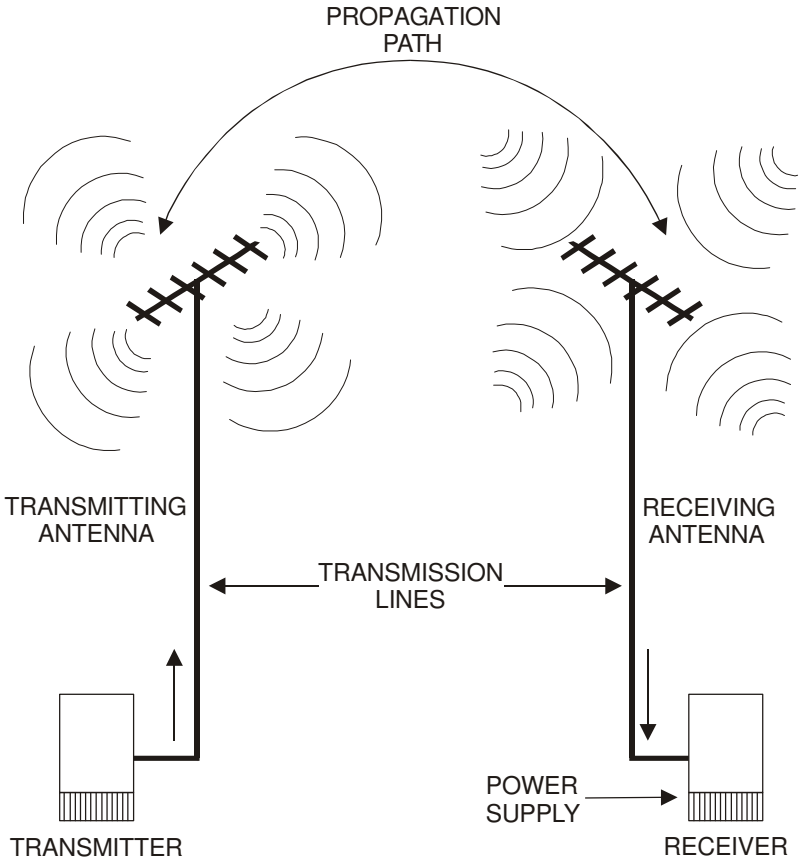

Figure 1-3. Typical Radio Link.

PROPAGATION FUNDAMENTALS

Earth's Atmosphere

Propagation usually takes place within the Earth's atmosphere. The atmosphere surrounding the Earth is divided into several layers, each possessing unique characteristics. The first layer, starting at the Earth's surface and extending to a height of about 10 kilometers (km), is the troposphere. In this layer, the air temperature decreases with altitude at the rate of about 2.5°C every 300 meters.

The second layer of the atmosphere is the stratosphere, which occupies an altitude range extending from about 10 km to 50 km. This layer of air remains at a nearly constant temperature of about -65°C.

Beginning at about 50 km and extending upward to more than 500 km is the ionosphere. The ionosphere gets its name because the molecules of its atmosphere are ionized, i.e., electrons have been stripped away from atoms by the constant bombardment of the Sun's rays and other high energy particles released by the Sun. Because of the large quantities of free electrons, the ionosphere is capable of interacting strongly on radio waves traveling through it.

Radio Wave Propagation

There are two principal ways radio waves travel from the transmitter to the receiver. One is by ground wave, directly from the transmitter to the receiver. The other is by sky wave, up to the ionosphere and refracted (bent downward) back to the Earth. Short-distance, all UHF, and upper VHF transmissions are by ground waves. Long-distance transmissions are principally by sky waves. SCR sets can use either ground wave or sky wave propagation for communications.

Ground Wave Propagation. Radio communications using ground wave propagation do not use or depend on waves refracted from the ionosphere (sky waves). Ground wave propagation is affected by the Earth's electrical characteristics and by the amount of diffraction (bending) of the waves along the Earth's curvature. The ground wave's strength at the receiver depends on the transmitter's power output and frequency, the Earth's shape and conductivity along the transmission path, and the local weather conditions. The ground wave includes three components: the direct wave, the ground reflected wave, and the surface wave (fig. 1-4).

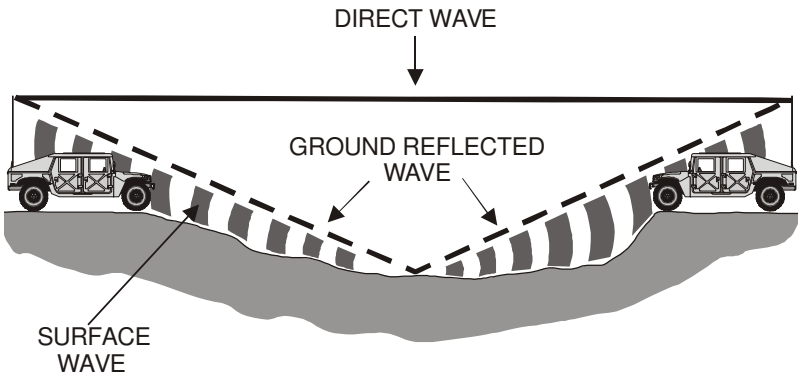

Figure 1-4. Ground Wave.

Direct Wave. **The direct wave travels directly from the transmitting antenna to the receiving antenna. The direct wave is limited to the LOS distance between the transmitting antenna and the receiving antenna plus the short distance added by atmospheric refraction and diffraction of the wave around the Earth's curvature. This distance can be extended by increasing the transmitting or the receiving antenna height, or both.**

Ground Reflected Wave. **The ground reflected wave reaches the receiving antenna after being reflected from the Earth's surface. Cancellation of the radio signal can occur when the ground reflected component and the direct wave component arrive at the receiving antenna at the same time and are 180° out of phase with each other.**

Surface Wave. **The surface wave follows the Earth's curvature. It is affected by the Earth's conductivity and dielectric constant.**

Frequency Characteristics Of Ground Waves. **Various frequencies determine which wave component will prevail along any given signal path. For example, when the Earth's conductivity is high and the frequency of a radiated signal is low, the surface wave is the predominant component. For frequencies below 10 MHz, the surface wave is sometimes the predominant component. However, above 10 MHz, the losses that are sustained by the surface wave component are so great that the other components (direct wave and sky wave) become predominant.**

At frequencies of 30 to 300 kHz, ground losses are very small, so the surface wave component follows the Earth's curvature. It can be used for long-distance communications provided the radio operator has enough power from the transmitter. The frequencies 300 kHz to 3 MHz are used for long-distance communications over sea water and for medium-distance communications over land.

At high frequencies, 3 to 30 MHz, the ground's conductivity is extremely important, especially above 10 MHz where the dielectric constant or conductivity of the Earth's surface determines how much signal absorption occurs. In general, the signal is strongest at the lower frequencies when the surface over which it travels has a high dielectric constant and conductivity.

Earth's Surface Conductivity. **The dielectric constant or Earth's surface conductivity determines how much of the surface wave signal energy will be absorbed or lost. Although the Earth's surface conductivity as a whole is generally poor, the conductivity of varying surface conditions, when compared one with an other, would be as stated in table 1-3.**

Table 1-3. Surface Conductivity.

Surface Type	Relative Conductivity
Large body fresh water	Very good
Ocean or sea water	Good
Flat or hilly loamy soil	Fair
Rocky terrain	Poor
Desert	Poor
Jungle	Very poor

Sky Wave Propagation. Radio communications that use sky wave propagation depend on the ionosphere to provide the signal path between the transmitting and receiving antennas.

Ionospheric Structure. **The ionosphere has four distinct layers. In the order of increasing heights and decreasing molecular densities, these layers are D, E, F1, and F2. During the day, when the rays of the Sun are directed toward that portion of the atmosphere, all four layers may be present. At night, the F1 and F2 layers seem to merge into a single F layer, and the D and E layers fade out. The actual number of layers, their height above the Earth, and their relative intensity of ionization vary constantly.**

The D layer exists only during the day and has little effect in bending the paths of HF radio waves. The main effect of the D layer is to attenuate HF waves when the transmission path is in sunlit regions.

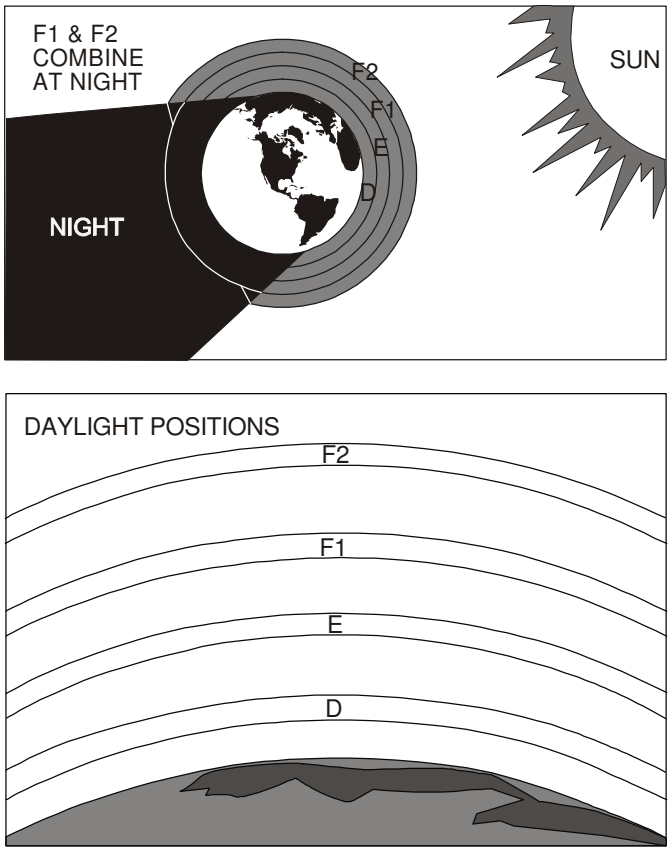
The E layer is used during the day for HF radio transmission over intermediate distances (less than 2,400 km/1,500 miles [mi]). At night the intensity of the E layer decreases, and it becomes useless for radio transmission.

The F layer exists at heights up to 380 km/240 mi above the Earth and is ionized all the time. It has two well-defined layers (F1 and F2) during the day, and one layer (F) at night. At night the F layer remains at a height of about 260 km/170 mi and is useful for long-range radio communications (over 2,400 km/1,500 mi). The F2 layer is the most useful for long-range radio communications, even though its degree of ionization varies appreciably from day to day (fig. 1-5).

The Earth's rotation around the Sun and changes in the Sun's activity contribute to ionospheric variations. There are two main classes of these variations: regular (predictable) and irregular, occuring from abnormal behavior of the Sun.

Regular Ionospheric Variations. **The four regular variations are—**

- **Daily: caused by the rotation of the Earth.**
- **Seasonal: caused by the north and south progression of the Sun.**
- **27-day: caused by the rotation of the Sun on its axis.**
- **1-year: caused by the sunspot activity cycle going from maximum through minimum back to maximum levels of intensity.**



F2 250-500 km (250-420 km at night)
F1 200-250 km
E 90-130 km
D 75-90 km

Figure 1-5. Ionospheric Structure.

Irregular Ionospheric Variations. **In planning a communications system, the current status of the four regular variations must be anticipated. There are also unpredictable irregular variations that must be considered. They have a degrading effect (at times blanking out communications) which cannot be controlled or compensated for at the present time. Some irregular variations are—**

- **Sporadic E. When excessively ionized, the E layer often blanks out the reflections from the higher layers. It can also cause unexpected propagation of signals hundreds of miles beyond the normal range. This effect can occur at any time.**
- **Sudden ionospheric disturbance (SID). A sudden ionospheric disturbance coincides with a bright solar eruption and causes abnormal ionization of the D layer. This effect causes total absorption of all frequencies above approximately 1 MHz. It can occur without warning during daylight hours and can last from a few minutes to several hours. When it occurs, receivers seem to go dead.**
- **Ionospheric storms. During these storms, sky wave reception above approximately 1.5 MHz shows low intensity and is subject to a type of rapid blasting and fading called flutter fading. These storms may last from several hours to days and usually extend over the entire Earth.**

Sunspots. **Sunspots generate bursts of radiation that cause high levels of ionization. The more sunspots, the greater the ionization. During periods of low sunspot activity, frequencies above 20 MHz tend to be unusable because the E and F layers are too weakly ionized to reflect signals back to Earth. At the peak of the sunspot cycle, however, it is not unusual to have worldwide propagation on frequencies above 30 MHz.**

Frequency Characteristics in the Ionosphere. **The range of long-distance radio transmission is determined primarily by the ionization density of each layer. The higher the frequency, the greater the ionization density required to reflect radio waves back to Earth. The upper (E and F) layers reflect the higher frequencies because they are the most highly ionized. The D layer, which is the least ionized, does not reflect frequencies above approximately 500 kHz. Thus, at any given time and for each ionized layer, there is an upper frequency limit at which radio waves sent vertically upward are reflected back to Earth. This limit is called the critical frequency.**

Radio waves directed vertically at frequencies higher than the critical frequency pass through the ionized layer out into space. All radio waves directed vertically into the ionosphere at frequencies lower than the critical frequency are reflected back to Earth. Radio waves used in communications are generally directed towards the ionosphere at some oblique angle, called the angle of incidence. Radio waves at frequencies above the critical frequency will be reflected back to Earth if transmitted at angles of incidence smaller than a certain angle, called the critical angle. At the critical angle, and at all angles larger than the critical angle, the radio waves pass through the ionosphere if the frequency is higher than the critical frequency. As the angle of transmission decreases, an angle is reached at which the radio waves are reflected back to Earth.

Transmission Paths. **Sky wave propagation refers to those types of radio transmissions that depend on the ionosphere to provide signal paths between transmitters and receivers.**

The distance from the transmitting antenna to the place where the sky waves first return to Earth is the skip distance. The skip distance depends on the angle of incidence, the operating frequency, and the

ionosphere's height and density. The antenna's height, in relation to the operating frequency, affects the angle that transmitted radio waves strike and penetrate the ionosphere and then return to Earth. This angle of incidence can be controlled to obtain the desired coverage area. Lowering the antenna height increases the angle of transmission and provides broad and even signal patterns in a large area.

Using near-vertical transmission paths is known as near-vertical incidence sky wave (NVIS). Raising the antenna height lowers the angle of incidence. Lowering the angle of incidence produces a skip zone in which no usable signal is received. This area is bounded by the outer edge of usable ground wave propagation and the point nearest the antenna at which the sky wave returns to Earth. In short-range communications situations, the skip zone is an undesirable condition. However, low angles of incidence make long-distance communications possible.

When a transmitted wave is reflected back to the Earth's surface, the Earth absorbs part of the energy. The remaining energy is reflected back into the ionosphere to be reflected back again. This means of transmission—alternately reflecting the radio wave between the ionosphere and the Earth—is called hops. Hops enable radio waves to be received at great distances from the point of origin.

Fading. Fading is the periodic increase and decrease of received signal strength. Fading occurs when a radio signal is received over a long-distance path in the high frequency range. The precise origin of this fading is seldom understood. There is little common knowledge of what precautions to take to reduce or eliminate fading's troublesome effects. Fading associated with sky wave paths is the greatest detriment to reliable communications. Too often, those responsible for communication circuits rely on raising the transmitter power or increasing antenna gain to overcome fading. Unfortunately, such actions often do not work and seldom improve

reliability. Only when the signal level fades down below the background noise level for an appreciable fraction of time will increased transmitter power or antenna gain yield an overall circuit improvement. Choosing the correct frequency and using transmitting and receiving equipment intelligently ensure a strong and reliable receiving signal, even when low power is used.

Maximum Usable and Lowest Usable Frequencies. Using a given ionized layer and a transmitting antenna with a fixed angle of radiation, there is a maximum frequency at which a radio wave will return to Earth at a given distance. This frequency is called the maximum usable frequency (MUF). It is the monthly median of the daily highest frequency that is predicted for sky wave transmission over a particular path at a particular hour of the day. The MUF is always higher than the critical frequency because the angle of incidence is less than 90°. If the distance between the transmitter and the receiver is increased, the MUF will also increase. Radio waves lose some of their energy through absorption by the D layer and a portion of the E layer at certain transmission frequencies.

The total absorption is less and communications more satisfactory as higher frequencies are used—up to the level of the MUF. The absorption rate is greatest for frequencies ranging from approximately 500 kHz to 2 MHz during the day. At night the absorption rate decreases for all frequencies. As the frequency of transmission over any sky wave path decreases from high to low frequencies, a frequency will be reached at which the received signal overrides the level of atmospheric and other radio noise interference. This is called the lowest useful frequency (LUF) because frequencies lower than the LUF are too weak for useful communications. The LUF depends on the transmitter power output as well as the transmission distance. When the LUF is greater than the MUF, no sky wave transmission is possible.

Propagation Prediction. **Although a detailed discussion of propagation prediction methods is beyond the scope of this publication, it should be noted that propagation predictions can be obtained from a system planning, engineering, and evaluation device (SPEED).**

Other Factors Affecting Propagation

In the VHF and UHF ranges, extending from 30 to 300 MHz and beyond, the presence of objects (e.g., buildings or towers) may produce strong reflections that arrive at the receiving antenna in such a way that they cancel the signal from the desired propagation path and render communications impossible. Most Marines are familiar with distant TV station reception interference caused by high-flying aircraft. The signal bouncing off of the aircraft alternately cancels and reinforces the direct signal from the TV station as the aircraft changes position relative to the transmitting and receiving antennas.

This same interference can adversely affect the ordinary voice communications circuit at VHF and UHF, rendering the received signal unintelligible for brief periods of time. Receiver locations that avoid the proximity of an airfield should be chosen if possible. Avoid locating transmitters and receivers where an airfield is at or near midpoint of the propagation path of frequencies above 20 MHz.

Many other things may affect the propagation of a radio wave. Hills, mountains, buildings, water towers, tall fences, aircraft, and even other antennas can have a marked affect on the condition and reliability of a given propagation path. Conductivity of the local ground or body of water can greatly alter the strength of the transmitted or received signal. Energy radiation from the Sun's surface also greatly affects conditions within the ionosphere and alters the characteristics of long-distance propagation at 2 to 30 MHz.

Path Loss

Radio waves become weaker as they spread from the transmitter. The ratio of received power to transmitted power is called path loss. LOS paths at VHF and UHF require relatively little power since the total path loss at the radio horizon is only about 25 decibels (dB) greater than the path loss over the same distance in free space (absence of ground). This additional loss results from some energy being reflected from the ground, canceling part of the direct wave energy. This is unavoidable in almost every practical case. The total path loss for an LOS path above average terrain varies with the following factors: total path loss between transmitting and receiving antenna terminals, frequency, distance, transmitting antenna gain, and receiving antenna gain.

Reflected Waves

Often, it is possible to communicate beyond the normal LOS distance by exploiting the reflection from a tall building, nearby mountain, or water tower (fig. 1-6 on page 1-20). If the top portion of a structure or hill can be seen readily by both transmitting and receiving antennas, it may be possible to achieve practical communications by directing both antennas toward the point of maximum reflection. If the reflecting object is very large in terms of a wavelength, the path loss, including the reflection, can be very low.

If a structure or hill exists adjacent to an LOS path, reflected energy may either add to or subtract from the energy arriving from the direct path. If the reflected energy arrives at the receiving antenna with the same amplitude (strength) as the direct signal but has the opposite phase, both signals will cancel and communication will be impossible. However, if the same condition exists but both signals arrive in phase, they will add and double the signal strength. These

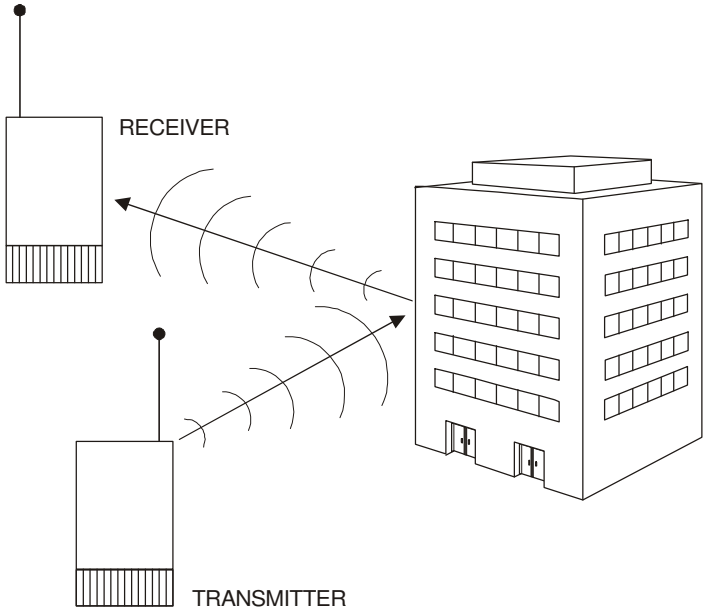


Figure 1-6. Reflected Waves.

two conditions represent destructive and constructive combinations of the reflected and direct waves.

Reflection from the ground at the common midpoint between the receiving and transmitting antennas may also arrive in a constructive or destructive manner. Generally, in the VHF and UHF range, the reflected wave is out of phase (destructive) with respect to the direct wave at vertical angles less than a few degrees above the horizon. However, since the ground is not a perfect conductor, the amplitude of the reflected wave seldom approaches that of the direct wave. Thus, even though the two arrive out of phase, complete cancellation does not occur. Some improvement may result from using vertical polarization rather than horizontal polarization

over LOS paths because there tends to be less phase difference between direct and reflected waves. The difference is usually less than 10 dB, however, in favor of vertical polarization.

Diffraction

Unlike the ship passing beyond the visual horizon, a radio wave does not fade out completely when it reaches the radio horizon. A small amount of radio energy travels beyond the radio horizon by a process called diffraction. Diffraction also occurs when a light source is held near an opaque object, casting a shadow on a surface behind it. Near the edge of the shadow a narrow band can be seen which is neither completely light nor dark. The transition from total light to total darkness does not occur abruptly, but changes smoothly as the light is diffracted.

A radio wave passing over either the curved surface of the Earth or a mountain ridge behaves in much the same fashion as a light wave. For example, people living in a valley below a high, sharp, mountain ridge can often receive a TV station located many miles below on the other side. Figure 1-7 illustrates how radio waves from the

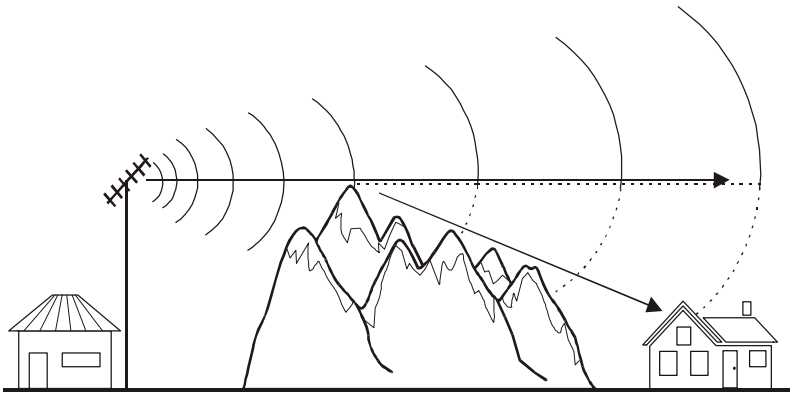

Figure 1-7. Diffracted Wave.

TV station are diffracted by the mountain ridge and bent downward in the direction of the village. It is emphasized, however, that the energy decays very rapidly as the angle of propagation departs from the straight LOS path. Typically, a diffracted signal may undergo a reduction of 30 to 40 dB by being bent only 5 feet by a mountain ridge. The actual amount of diffracted signal depends on the shape of the surface, the frequency, the diffraction angle, and many other factors. It is sufficient to say that there are times when the use of diffraction becomes practical as a means for communicating in the VHF and UHF over long distances.

Tropospheric Refraction, Ducting, and Scattering

Refraction is the bending of a wave as it passes through air layers of different density (refractive index). In semitropical regions, a layer of air 5 to 100 meters thick with distinctive characteristics may form close to the ground, usually the result of a temperature inversion. For example, on an unusually warm day after a rainy spell, the Sun may heat up the ground and create a layer of warm, moist air. After sunset, the air a few meters above the ground will cool very rapidly while the moisture in the air close to the ground serves as a blanket for the remaining heat. After a few hours, a sizable difference in temperature may exist between the air near the ground and the air at a height of 10 to 20 meters, resulting in a marked difference in air pressure. Thus, the air near the ground is considerably denser than the air higher up. This condition may exist over an area of several hundred square kilometers or over a long area of land near a seacoast. When such an air mass forms, it usually remains stable until dawn, when the ground begins to cool and the temperature inversion ends.

When a VHF or UHF radio wave is launched within such air mass, it may bend or become *trapped* (forced to follow the inversion layer). This layer then acts as a *duct* between the transmitting

antenna and a distant receiving site. The effects of such ducting can be seen frequently during the year in certain locations where TV or VHF FM stations are received over paths of several hundred kilometers. The total path loss within such a *duct* is usually very low and may exceed the free space loss by only a few dBs.

It is also possible to communicate over long distances by means of tropospheric scatter. At altitudes of a few kilometers, the air mass has varying temperature, pressure, and moisture content. Small fluctuations in tropospheric characteristics at high altitude create *blobs*. Within a blob, the temperature, pressure, and humidity are different from the surrounding air. If the difference is large enough, it may modify the refractive index at VHF and UHF. A random distribution of these blobs exists at various altitudes at all times. If a high-power transmitter (greater than 1 kW) and high gain antenna (10 dB or more) are used, sufficient energy may be scattered from these blobs down to the receiver to make reliable communication possible over several hundred kilometers. Communication circuits employing this mode of propagation must use very sensitive receivers and some form of diversity to reduce the effects of the rapid and deep fading. Scatter propagation is usually limited to path distances of less than about 500 km.

NOISE

Noise consists of all undesired radio signals, manmade or natural. Noise masks and degrades useful information reception. The radio signal's strength is of little importance if the signal power is greater than the received noise power. This is why S/N ratio is the most important quantity in a receiving system. Increasing receiver amplification cannot improve the S/N ratio since both signal and noise will be amplified equally and S/N ratio will remain unchanged. Normally, receivers have more than enough amplification.

Natural Noise

Natural noise has two principle sources: thunderstorms (atmospheric noise) and stars (galactic noise). Both sources generate sharp pulses of electromagnetic energy over all frequencies. The pulses propagate according to the same laws as manmade signals, and receiving systems must accept them along with the desired signal. Atmospheric noise is dominant from 0 to 5 MHz, and galactic noise is most important at all higher frequencies. Low frequency transmitters must generate very strong signals to overcome noise. Strong signals and strong noise mean that the receiving antenna does not have to be large to collect a usable signal (a few hundred microvolts). A 1.5 meter tuned whip will deliver adequately all of the signals that can be received at frequencies below 1 MHz.

Manmade Noise

Manmade noise is a product of urban civilization that appears wherever electric power is used. It is generated almost anywhere that there is an electric arc (e.g., automobile ignition systems, power lines, motors, arc welders, fluorescent lights). Each source is small, but there are so many that together they can completely hide a weak signal that would be above the natural noise in rural areas. Manmade noise is troublesome when the receiving antenna is near the source, but being near the source gives the noise waves characteristics that can be exploited. Waves near a source tend to be vertically polarized. A horizontally polarized receiving antenna will generally receive less noise than a vertically polarized antenna.

Manmade noise currents are induced by any conductors near the source, including the antenna, transmission line, and equipment cases. If the antenna and transmission line are balanced with respect to the ground, then the noise voltages will be balanced and cancel

with respect to the receiver input terminals (zero voltage across terminals), and this noise will not be received. Near-perfect balance is difficult to achieve, but any balance helps.

Other ways to avoid manmade noise are to locate the most troublesome sources and turn them off, or move the receiving system away from them. Moving a kilometer away from a busy street or highway will significantly reduce noise. Although broadband receiving antennas are convenient because they do not have to be tuned to each working frequency, sometimes a narrowband antenna can make the difference between communicating and not communicating. The HF band is now so crowded with users that interference and noise, not signal strength, are the main reasons for poor communications. A narrowband antenna will reject strong interfering signals near the desired frequency and help maintain good communications.

(reverse blank)

Chapter 2

Antenna Fundamentals

All radios, whether transmitting or receiving, require some sort of antenna. The antenna accepts power from the transmitter and launches it into space as an electromagnetic or radio wave. At the receiving end of the circuit, a similar antenna collects energy from the passing electromagnetic wave and converts it into an alternating electric current or signal that the receiver can detect.

How well antennas launch and collect electromagnetic waves directly influences communications reliability and quality. The function of an antenna depends on whether it is transmitting or receiving.

A transmitting antenna transforms the output radio frequency (RF) energy produced by a radio transmitter (RF output power) into an electromagnetic field that is radiated through space. The transmitting antenna converts energy from one form to another form. The receiving antenna reverses this process. It transforms the electromagnetic field into RF energy that is delivered to a radio receiver.

Section I. Concepts and Terms

To select the right antennas for a radio circuit, certain concepts and terms must be understood. This section defines several basic terms and relationships which will help the reader understand antenna fundamentals. These include: forming a radio wave, radiation fields and patterns, polarization, directionality, resonance, reception, reciprocity, impedance, bandwidth, gain, and take-off angle.

FORMING A RADIO WAVE

When an alternating electric current flows through a conductor (wire), electric and magnetic fields are created around the conductor. If the length of the conductor is very short compared to a wavelength, the electric and magnetic fields will generally die out within a distance of one or two wavelengths. However, as the conductor is lengthened, the intensity of the fields enlarge. Thus, an ever-increasing amount of energy escapes into space. When the length of the wire approaches one-half of a wavelength at the frequency of the applied alternating current, most of the energy will escape in the form of electromagnetic radiation. For effective communications to occur, the following must exist: alternating electric energy in the form of a transmitter, a conductor or a wire, an electric current flowing through the wire, and the generation of both electric and magnetic fields in the space surrounding the wire.

RADIATION

Once a wire is connected to a transmitter and properly grounded, it begins to oscillate electrically, causing the wave to convert nearly all of the transmitter power into an electromagnetic radio wave. The electromagnetic energy is created by the alternating flow of electrons impressed on the bottom end of the wire. The electrons travel

upward on the wire to the top, where they have no place to go and are bounced back toward the lower end. As the electrons reach the lower end in phase, i.e., in step with the radio energy then being applied by the transmitter, the energy of their motion is strongly reinforced as they bounce back upward along the wire. This regenerative process sustains the oscillation. The wire is resonant at the frequency at which the source of energy is alternating.

The radio power supplied to a simple wire antenna appears nearly equally distributed throughout its length. The energy stored at any location along the wire is equal to the product of the voltage and the current at that point. If the voltage is high at a given point, the current must be low. If the current is high, the voltage must be low. The electric current is maximum near the bottom end of the wire.

Radiation Fields

When RF power is delivered to an antenna, two fields evolve. One is an induction field, which is associated with the stored energy; the other is a radiation field. At the antenna, the intensities of these fields are large and are proportional to the amount of RF power delivered to the antenna. At a short distance from the antenna and beyond, only the radiation field remains. This field is composed of an electric component and a magnetic component (see fig. 2-1 on page 2-4).

The electric and magnetic fields (components) radiated from an antenna form the electromagnetic field. The electromagnetic field transmits and receives electromagnetic energy through free space. A radio wave is a moving electromagnetic field that has velocity in the direction of travel and components of electric intensity and magnetic intensity arranged at right angles to each other.

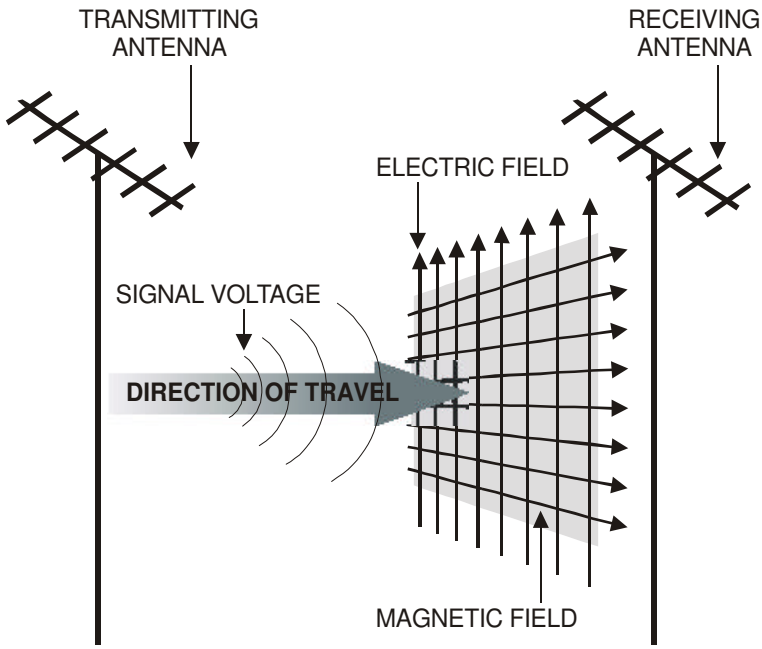

Figure 2-1. Radiation Fields.

Radiation Patterns

The radio signals radiated by an antenna form an electromagnetic field with a definite pattern, depending on the type of antenna used. This radiation pattern shows the antenna's directional characteristics. A vertical antenna radiates energy equally in all directions (omnidirectional), a horizontal antenna is mainly bidirectional, and a unidirectional antenna radiates energy in one direction. However, the patterns are usually distorted by nearby obstructions or terrain features. The full- or solid-radiation pattern is represented as a three-dimensional figure that looks somewhat like a doughnut with a transmitting antenna in the center (fig 2-2).

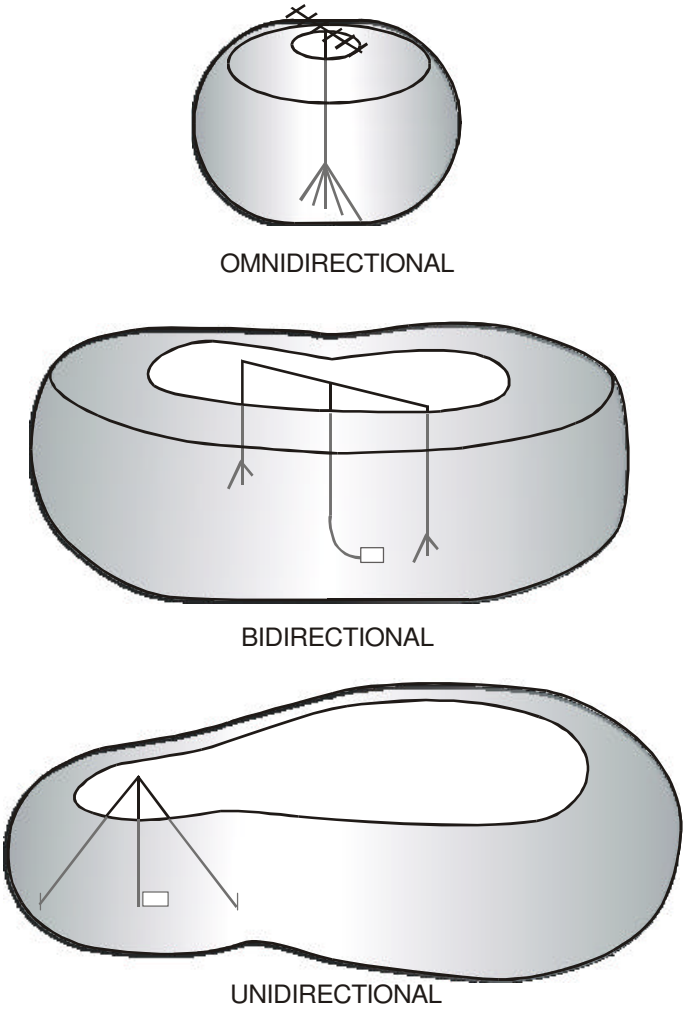

Figure 2-2. Radiation Patterns.

POLARIZATION

A radiated wave's polarization is determined by the direction of the lines of force making up the electric field. If the lines of electric force are at right angles to the Earth's surface, the wave is vertically polarized (fig. 2-3). If the lines of electric force are parallel to the Earth's surface, the wave is horizontally polarized (fig. 2-4). When a single-wire antenna extracts (receives) energy from a passing

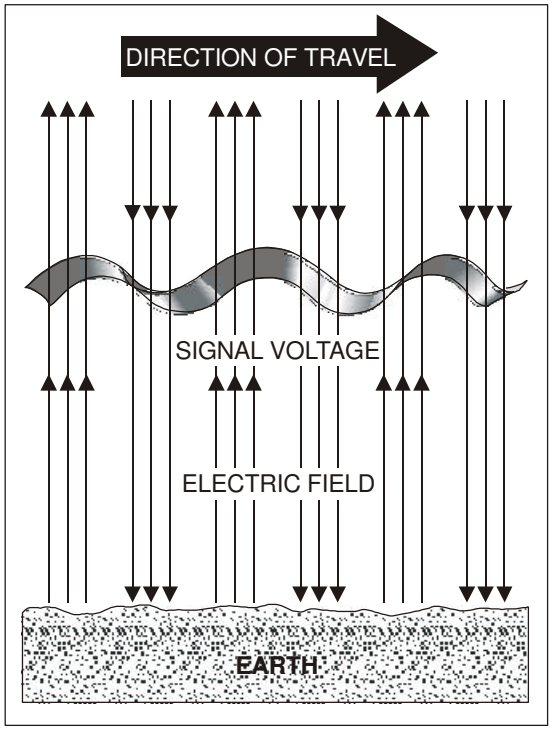

Figure 2-3. Vertical Polarization.

radio wave, maximum pickup results if the antenna is oriented in the same direction as the electric field component. A vertical antenna receives vertically polarized waves, and a horizontal antenna receives horizontally polarized waves. If the field rotates as the waves travel through space, both horizontal and vertical components of the field exist, and the wave is elliptically polarized.

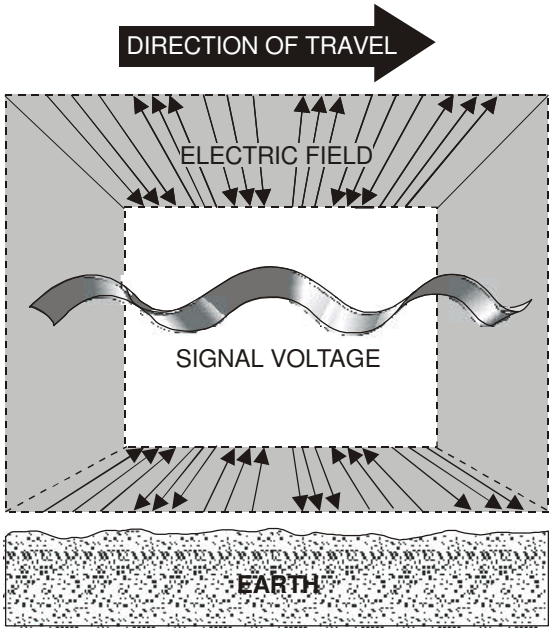

Figure 2-4. Horizontal Polarization.

Polarization Requirements for Various Frequencies

At medium and low frequencies, ground wave transmission is used extensively, and it is necessary to use vertical polarization. Vertical lines of force are perpendicular to the ground, and the radio wave can travel a considerable distance along the ground surface with a minimum amount of loss. Because the Earth acts as a relatively good conductor at low frequencies, horizontal lines of electric force are shorted out, and the useful range with the horizontal polarization is limited.

At high frequencies, with sky wave transmission, it makes little difference whether horizontal or vertical polarization is used. The sky wave, after being reflected by the ionosphere, arrives at the receiving antenna elliptically polarized. Therefore, the transmitting and receiving antennas can be mounted either horizontally or vertically. Horizontal antennas are preferred, since they can be made to radiate effectively at high angles and have inherent directional properties.

For frequencies in the VHF or UHF range, either horizontal or vertical polarization is satisfactory. Since the radio wave travels directly from the transmitting antenna to the receiving antenna, the original polarization produced at the transmitting antenna is maintained as the wave travels to the receiving antenna. If a horizontal antenna is used for transmitting, a horizontal antenna must be used for receiving.

Satellites and satellite terminals use circular polarization. Circular polarization describes a wave whose plane of polarization rotates through 360° as it progresses forward. The rotation can be clockwise or counterclockwise (see fig. 2-5). Circular polarization occurs when equal magnitudes of vertically and horizontally polarized waves are combined with a phase difference of 90°. Rotation in one direction or the other depends on the phase relationship.

Advantages of Vertical Polarization

Simple vertical half-wave and quarter-wave antennas provide omnidirectional communications. This is desirable in communicating with a moving vehicle. The disadvantage is that it radiates equally to the enemy and friendly forces.

When antenna heights are limited to 3.05 meters (10 feet) or less over land, as in a vehicular installation, vertical polarization provides a stronger received signal at frequencies up to about 50 MHz. From about 50 to 100 MHz, there is only a slight improvement over horizontal polarization with antennas at the same height. Above 100 MHz, the difference in signal strength between vertical and horizontal polarization is small. However, when antennas are located near dense forests, horizontally polarized waves suffer lower losses than vertically polarized waves.

Vertically polarized radiation is somewhat less affected by reflections from aircraft flying over the transmission path. With horizontal polarization, such reflections cause variations in received signal

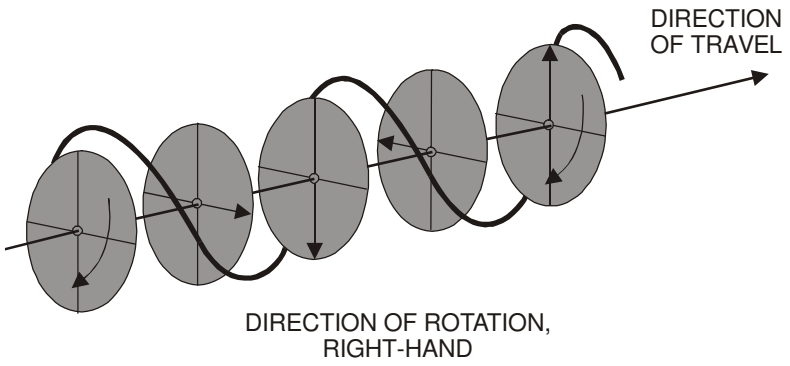

Figure 2-5. Circular Polarization.

strength. An example is the picture flutter in a television set when an aircraft interferes with the transmission path. This factor is important in areas where aircraft traffic is heavy.

When vertical polarization is used, less interference is produced or picked up from strong VHF and UHF transmissions (TV and FM broadcasts) because they use horizontal polarization. This factor is important when an antenna must be located in an urban area that has TV or FM broadcast stations.

Advantages of Horizontal Polarization

A simple horizontal half-wave antenna is bidirectional. This characteristic is useful in minimizing interference from certain directions.

Horizontal antennas are less likely to pick up manmade interference, which is ordinarily vertically polarized. When antennas are located near dense forests, horizontally polarized waves suffer lower losses than vertically polarized waves, especially above 100 MHz. Small changes in antenna location do not cause large variations in the field intensity of horizontally polarized waves when an antenna is located among trees or buildings. When vertical polarization is used, a change of only a few feet in the antenna location may have a significant effect on the received signal strength.

DIRECTIONALITY

Vertical receiving antennas accept radio signals equally from all horizontal directions, just as vertical transmitting antennas radiate equally in all horizontal directions. Because of this characteristic, other stations operating on the same or nearby frequencies may interfere with the desired signal and make reception difficult or

impossible. However, reception of a desired signal can be improved by using directional antennas.

Horizontal half-wave antennas accept radio signals from all directions. The strongest reception is received in a line perpendicular to the antenna (i.e., broadside, and the weakest reception is received from the direction of the ends of the antenna). Interfering signals can be eliminated or reduced by changing the antenna installation so that either end of the antenna points directly at the interfering station.

Communications over a radio circuit is satisfactory when the received signal is strong enough to override undesired signals and noise. The receiver must be within range of the transmitter. Increasing the transmitting power between two radio stations increases communications effectiveness. Also, changing the types of transmission, changing to a frequency that is not readily absorbed, or using a directional antenna aids in communications effectiveness.

Directional transmitting antennas concentrate radiation in a given direction and minimize radiation in other directions. A directional antenna may also be used to lessen interception by the enemy and interference with friendly stations.

RESONANCE

Antennas can be classified as either resonant or nonresonant, depending on their design. In a resonant antenna, almost all of the radio signal fed to the antenna is radiated. If the antenna is fed with a frequency other than the one for which it is resonant, much of the fed signal will be lost and will not be radiated. A resonant antenna will effectively radiate a radio signal for frequencies close to its design frequency (usually only 2 percent above or below the design

frequency). If a resonant antenna is used for a radio circuit, a separate antenna must be built for each frequency to be used on the radio circuit. A nonresonant antenna, on the other hand, will effectively radiate a broad range of frequencies with less efficiency. Resonant and nonresonant antennas are commonly used on tactical circuits. Resonance can be achieved in two ways: physically matching the length of the antenna to the wave and electronically matching the length of the antenna to the wave.

RECEPTION

The radio waves that leave the transmitting antenna will have an influence on and will be influenced by any electrons in their path. For example, as an HF wave enters the ionosphere, it is reflected or refracted back to earth by the action of free electrons in this region of the atmosphere. When the radio wave encounters the wire or metallic conductors of the receiving antenna, the radio wave's electric field will cause the electrons in the antenna to oscillate back and forth in step with the wave as it passes. The movement of these electrons within the antenna is the small alternating electrical current which is detected by the radio receiver.

When radio waves encounter electrons which are free to move under the influence of the wave's electric field, the free electrons oscillate in sympathy with the wave. This generates electric currents which then create waves of their own. These new waves are reflected or scattered waves. This process is electromagnetic scattering. All materials that are good electrical conductors reflect or scatter RF energy. Since a receiving antenna is a good conductor, it too acts as a scatterer. Only a portion of the energy which comes in contact with the antenna is converted into received electrical power; a sizable portion of the total power is re-radiated by the wire.

If an antenna is located within a congested urban environment or within a building, there are many objects which will scatter or re-raditate the energy in a manner that can be detrimental to reception. For example, the electric wiring inside a building can strongly re-radiate RF energy. If a receiving antenna is in close proximity to wires, it is possible for the reflected energy to cancel the energy received directly from the desired signal path. When this condition exists, the receiving antenna should be moved to another location within the room where the reflected and direct signals may reinforce rather than cancel each other.

RECIPROCITY

The various properties of an antenna apply equally, regardless of whether the antenna is used for transmitting or receiving. This is what is meant by reciprocity of antennas. For example, the more efficient a certain antenna is for transmitting, the more efficient it will be for receiving the same frequency. The directive properties of a given antenna will be the same whether it is used for transmission or reception.

For example, figure 2-6 on page 2-14 shows a particular antenna used with a transmitter radiating a maximum amount of energy at right angles to the antenna wire. There is a minimum amount of radiation along the axis of the antenna. If this same antenna is used as a receiving antenna, it receives best in the same directions in which it produced maximum radiation (i.e., at right angles to the axis of the antenna). There is a minimum amount of signal received from transmitters located in line with the antenna wire.

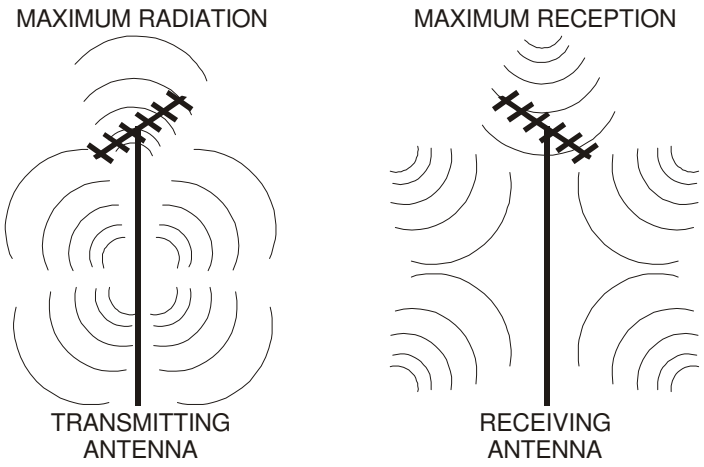

Figure 2-6. Reciprocity.

IMPEDANCE

Impedance is the relationship between voltage and current at any point in an alternating current circuit. The impedance of an antenna is equal to the ratio of the voltage to the current at the point on the antenna where the feed is connected (feed point). If the feed point is located at a point of maximum current, the antenna impedance is 20 to 100 ohms. If the feed point is moved to a maximum voltage point, the impedance is as much as 500 to 10,000 ohms.

The input impedance of an antenna depends on the conductivity or impedance of the ground. For example, if the ground is a simple stake driven about a meter into earth of average conductivity, the impedance of the monopole may be double or even triple the quoted values. Because this additional resistance occurs at a point on the antenna circuit where the current is high, a large amount of

transmitter power will dissipate as heat into the ground rather than radiated as intended. Therefore, it is essential to provide as good a ground or artificial ground (counterpoise) connection as possible when using a vertical whip or monopole.

The amount of power an antenna radiates depends on the amount of current which flows in it. Maximum power is radiated when there is maximum current flowing. Maximum current flows when the impedance is minimized—when the antenna is resonated so that its impedance is pure resistance. (When capacitive reactance is made equal to inductive reactance, they cancel each other, and impedance equals pure resistance.)

BANDWIDTH

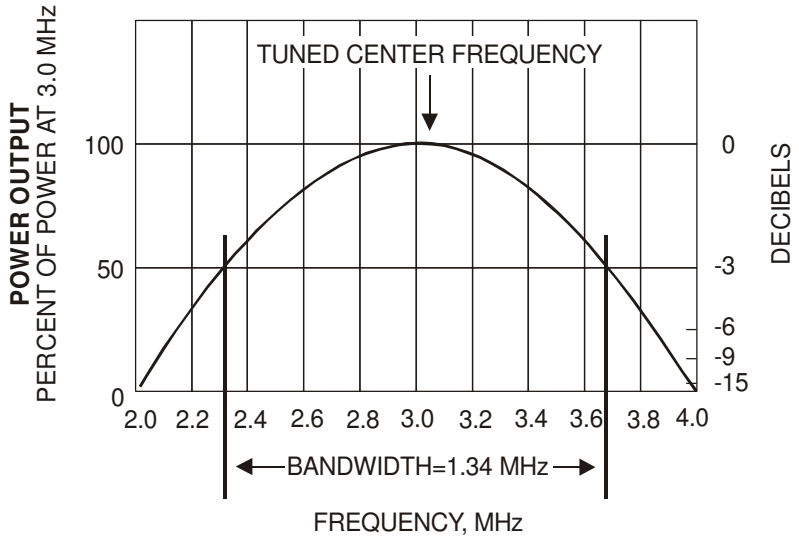
The bandwidth of an antenna is that frequency range over which it will perform within certain specified limits. These limits are with respect to impedance match, gain, and/or radiation pattern characteristics. Typical specification limits are—

- An impedance mismatch of less than 2:1 relative to some standard impedance such as 50 ohms.
- A loss in gain or efficiency of no more than 3 dB.
- A directivity pattern whose main beam is 13 dB greater than any of the side lobes, and a back lobe at least 15 dB below the main beam.
- Bandwidth is measured by changing the frequency of a constant-strength test signal above and below center frequency and measuring power output. The high and low frequencies, where power is one-half (-3 dB) of what it was at center, define the bandwidth. It is expressed as frequency (high minus low) or in percentage (high-low/center x 100%).

In the radio communication process, intelligence changes from speech or writing into a low frequency signal that is used to modulate, or cause change, in a much higher frequency radio signal. When transmitted by an antenna, these radio signals carry the intelligence to the receiving antenna, where it is picked up and reconverted into the original speech or writing. There are natural laws which limit the amount of intelligence or signal that can be transmitted and received at a given time. The more words per minute, the higher the rate and the modulation frequency, so a wider or greater bandwidth is needed. To transmit and receive all the intelligence necessary, the antenna bandwidth must be as wide or wider than the signal bandwidth, otherwise it will limit the signal frequencies, causing voices and writing to be unintelligible. Too wide a bandwidth is also bad, since it accepts extra voices and will degrade the S/N ratio. Figure 2-7 shows how signal bandwidth is defined and gives some examples of bandwidth required to transmit ordinary types of intelligence.

GAIN

The antenna's gain depends on its design. Transmitting antennas are designed for high efficiency in radiating energy, and receiving antennas are designed for high efficiency in picking up (gaining) energy. On many radio circuits, transmission is required between a transmitter and only one receiving station. Energy is radiated in one direction because it is useful only in that direction. Directional receiving antennas increase the energy gain in the favored direction and reduce the reception of unwanted noise and signals from other directions. Transmitting and receiving antennas should have small energy losses and should be efficient as radiators and receptors.



INTELLIGENCE	BANDWIDTH
Voice, AM	6.0 KHz
Voice, FM	46.0 KHz
One microsecond pulses	10,000.0 KHz

Bandwidths necessary to transmit and receive some ordinary kinds of intelligence

Figure 2-7. Bandwidth.

TAKE-OFF ANGLE

The antenna's take-off angle is the angle above the horizon that an antenna radiates the largest amount of energy (see fig. 2-8). VHF communications antennas are designed so that the energy is radiated parallel to the Earth (do not confuse take-off angle and polarization). The take-off angle of an HF communications antenna can determine whether a circuit is successful or not. HF sky wave antennas are designed for specific take-off angles, depending on the circuit distance. High take-off angles are used for short-range communications, and low take-off angles are used for long-range communications.

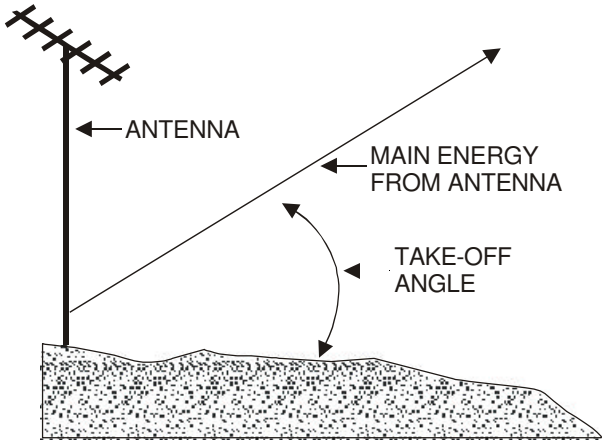


Figure 2-8. Take-Off Angle.

Section II. Ground Effects

Since most tactical antennas are erected over the Earth and not out in free space, except for those on satellites, the ground will alter the free space radiation patterns of antennas. The ground will also affect some of the electrical characteristics of an antenna. It has the greatest effect on those antennas that must be mounted relatively close to the ground in terms of wavelength. For example, medium- and high-frequency antennas, elevated above the ground by only a fraction of a wavelength, will have radiation patterns that are quite different from the free-space patterns.

GROUNDED ANTENNA THEORY

The ground is a good conductor for medium and low frequencies and acts as a large mirror for the radiated energy. The ground reflects a large amount of energy that is radiated downward from an antenna mounted over it. Using this characteristic of the ground, an antenna only a quarter-wavelength long can be made into the equivalent of a half-wave antenna. A quarter-wave antenna erected vertically, with its lower end connected electrically to the ground (fig. 2-9 on page 2-20), behaves like a half-wave antenna. The ground takes the place of the missing quarter-wavelength, and the reflections supply that part of the radiated energy that normally would be supplied by the lower half of an ungrounded half-wave antenna.

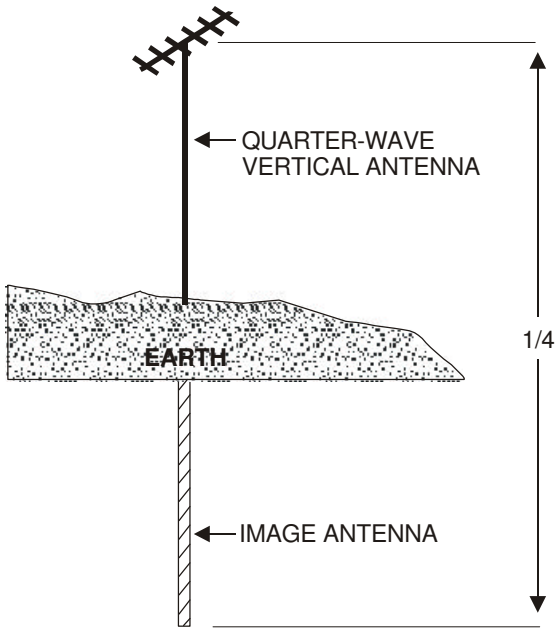

Figure 2-9. Quarter-Wave Antenna Connected to Ground.

TYPES OF GROUNDS

When grounded antennas are used, it is especially important that the ground has as high a conductivity as possible. This reduces ground losses and provides the best possible reflecting surface for the down-going radiated energy from the antenna. At low and medium frequencies, the ground acts as a good conductor. The ground connection must be made in such a way as to introduce the least possible amount of resistance to ground. At higher frequencies, artificial grounds constructed of large metal surfaces are common.

The ground connections take many forms, depending on the type of installation and the loss that can be tolerated. In many simple field installations, the ground connection is made by one or more metal rods driven into the soil. Where more satisfactory arrangements cannot be made, ground leads can be connected to existing devices which are grounded. Metal structures or underground pipe systems are commonly used as ground connections. In an emergency, a ground connection can be made by forcing one or more bayonets into the soil.

When an antenna must be erected over soil with low conductivity, treat the soil to reduce resistance. Treat the soil with substances that are highly conductive when in solution. Some of these substances, listed in order of preference, are sodium chloride (common salt), calcium chloride, copper sulfate (blue vitriol), magnesium sulfate (Epsom salt), and potassium nitrate (saltpeter). The amount required depends on the type of soil and its moisture content.

WARNING

WHEN THESE SUBSTANCES ARE USED, IT IS IMPORTANT THAT THEY DO NOT GET INTO NEARBY DRINKING WATER SUPPLIES.

For simple installations in the field, a single ground rod can be fabricated from pipe or conduit. It is important that a low resistance connection be made between the ground wire and the ground rod. The rod should be cleaned thoroughly by scraping and sandpapering at the point where the connection is to be made, and a clean ground clamp should be installed. A ground wire can then be soldered or joined to the clamp. This joint should be covered with tape to prevent an increase in resistance because of oxidation.

Counterpoise

When an actual ground connection cannot be used because of the high resistance of the soil or because a large buried ground system is not practical, a counterpoise may be used to replace the usual direct ground connection. The counterpoise (fig. 2-10) consists of a device made of wire, which is erected a short distance above the ground and insulated from it. The size of the counterpoise should be at least equal to or larger than the size of the antenna.

When the antenna is mounted vertically, the counterpoise should be made into a simple geometric pattern. Perfect symmetry is not required. The counterpoise appears to the antenna as an artificial ground that helps to produce the required radiation pattern.

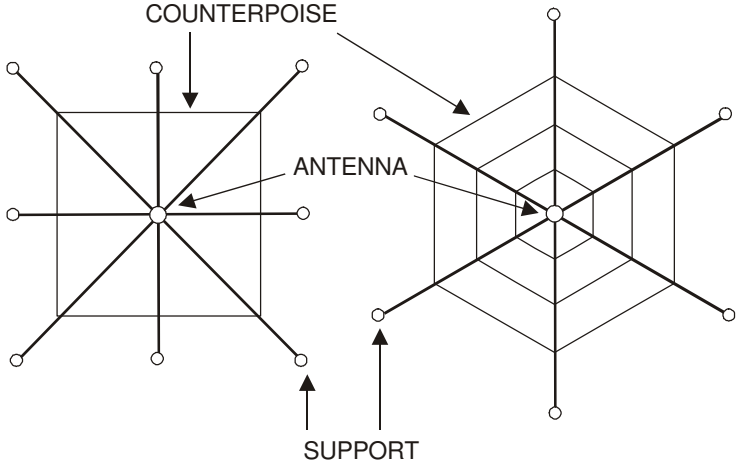

Figure 2-10. Wire Counterpoise.

In some VHF antenna installations on vehicles, the metal roof of the vehicle (or shelter) is used as a counterpoise for the antenna. Small counterpoises of metal mesh are sometimes used with special VHF antennas that must be located a considerable distance above the ground.

Ground Screen

A ground screen consists of a fairly large area of metal mesh or screen that is laid on the surface of the ground under the antenna. There are two specific advantages to using ground screens. First, the ground screen reduces ground absorption losses that occur when an antenna is erected over ground with poor conductivity. Second, the height of the antenna can be set accurately, and the radiation resistance of the antenna can be determined more accurately.

Section III. Calculating Antenna Length

An antenna's length must be considered in two ways: physical and electrical. The two are never the same. The reduced velocity of the wave on the antenna and a capacitive effect (end effect) make the antenna seem longer electrically than physically. The contributing factors are the ratio of the diameter of the antenna to its length and the capacitive effect of terminal equipment (e.g., insulators or clamps) used to support the antenna.

To calculate the antenna's physical length, use a correction of 0.95 for frequencies between 3 and 50 MHz. The figures given are for a half-wave antenna.

$$\text{Length (meters)} = \frac{150 \times 0.95}{\text{Frequency in MHz}} = \frac{142.50}{\text{Frequency in MHz}}$$

$$\text{Length (feet)} = \frac{492 \times 0.95}{\text{Frequency in MHz}} = \frac{468}{\text{Frequency in MHz}}$$

The length of a long-wire antenna (one wavelength or longer) for harmonic operation is calculated by using the following formula, where N = number of half-wavelengths in the total length of the antenna.

$$\text{Length (meters)} = \frac{150\ (N - 0.05)}{\text{Frequency in MHz}}$$

$$\text{Length (feet)} = \frac{492\ (N - 0.05)}{\text{Frequency in MHz}}$$

Example: 3 half-wavelengths at 7 MHz is—

$$\text{Length (meters)} = \frac{150\ (N - 0.05)}{\text{Frequency in MHz}}$$

$$= \frac{150\ (3 - .05)}{7}$$

$$= \frac{150 \times 2.95}{7}$$

$$= \frac{442.50}{7}$$

$$= 63.2 \text{ meters}$$

Section IV. Antenna Orientation

The orientation of an antenna is extremely important. Determining the position of an antenna in relation to the points of the compass can make the difference between a marginal and good radio circuit.

AZIMUTH

If the azimuth of the radio's path is not provided, determine it by the best available means. The accuracy required depends on the radiation pattern of the directional antenna. If the antenna beamwidth is very wide (e.g., 90° angle between half-power points) an error of

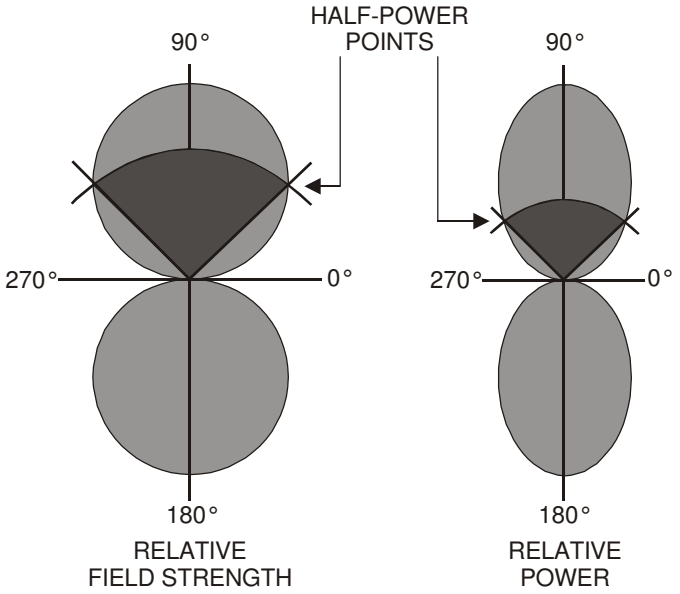

Figure 2-11. Beamwidth Measured on Relative Field Strength and Relative Power Patterns.

10° is of little consequence. In transportable operation, the rhombic and vee antennas may have such a narrow beam that great accuracy is required to determine azimuth. The antenna should be erected for the correct azimuth. Great accuracy is not required to erect broad-beam antennas.

Unless a line of known azimuth is available at the site, the direction of the path is best determined by a magnetic compass. Figure 2-12 on page 2-28 is a map of magnetic declination, showing the variation of the compass needle from the true north. When the compass is held so that the needle points to the direction indicated for the location on the map, all directions indicated by the compass will be true.

Improvement of Marginal Communications

It may not always be feasible to orient directional antennas to the correct azimuth of the desired radio path, and marginal communications may suffer. To improve marginal communications—

- Check, tighten, and tape cable couplings and connections.
- Retune all transmitters and receivers in the circuit.
- Check that the antennas are adjusted for proper operating frequency.
- Change the heights of antennas.
- Move the antenna a short distance away and in different locations from its original location.
- Separate transmitters from receiving equipment, if feasible.

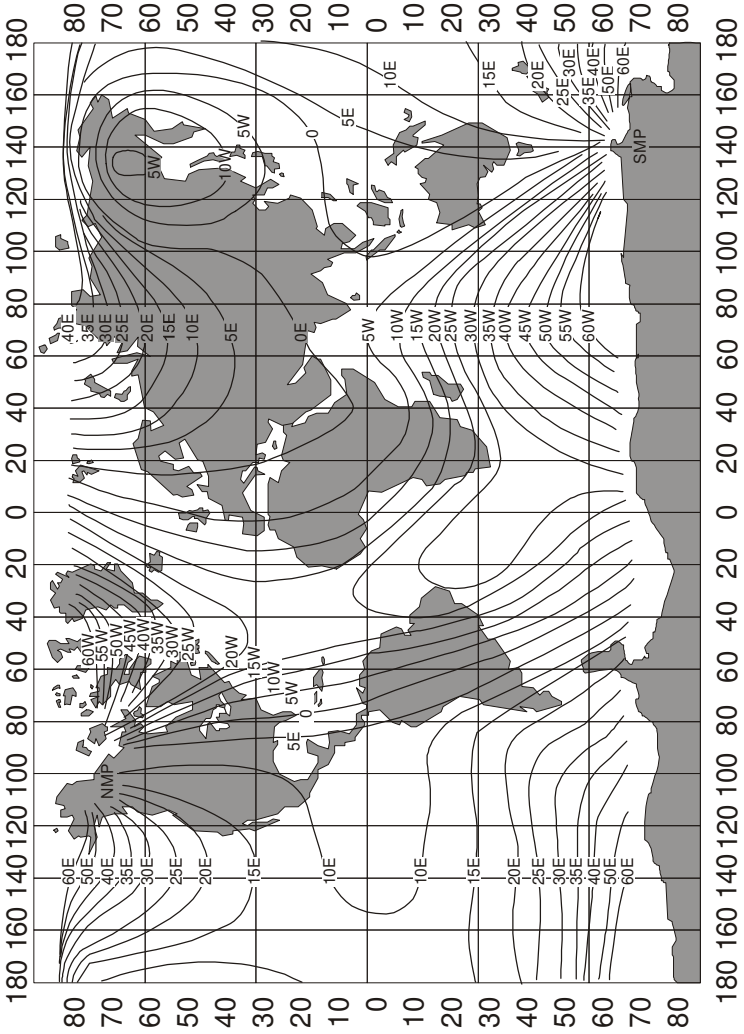

Figure 2-12. Magnetic Declination Over the World.

Transmission and Reception of Strong Signals

After an adequate site has been selected and the proper antenna orientation obtained, the signal level at the receiver will be proportional to the strength of the transmitted signal.

WARNING

EXCESSIVE SIGNAL STRENGTH MAY RESULT IN ENEMY INTERCEPT AND INTERFERENCE OR IN YOUR INTERFERENCE WITH ADJACENT FREQUENCIES.

If a high-gain antenna is used, a stronger signal can be obtained. Losses between the antenna and the equipment can be reduced by using a high quality transmission line, as short as possible, and properly matched at both ends.

WARNING

BE EXTREMELY CAREFUL WHEN PUTTING UP, TAKING DOWN, OR MOVING ANTENNAS LOCATED NEAR HIGH VOLTAGE OR COMMECIAL POWER LINES. ANTENNA CONTACT WITH THESE CAN AND MAY RESULT IN ELECTROCUTION OR SEVERE INJURY TO PERSONNEL HOLDING THE ANTENNA OR THE CONNECTING GUY WIRES AND CABLES.

(reverse blank)

Chapter 3

Transmission Lines

Transmission lines (antenna feed lines) conduct or guide electrical energy from the transmitter to the receiver. This chapter is oriented primarily toward transmission lines with field expedient antennas. For standard issue radios and antennas, use the issued coaxial cable. As long as radios, cables, and antennas are maintained in working order, they will operate as designed and won't require any adjustments or changes based on the information in this chapter.

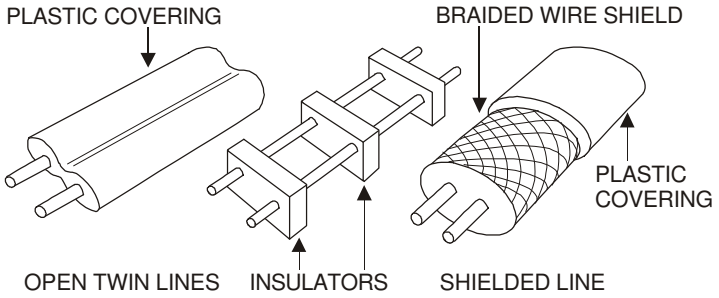
PROPERTIES

Transmission Line Types

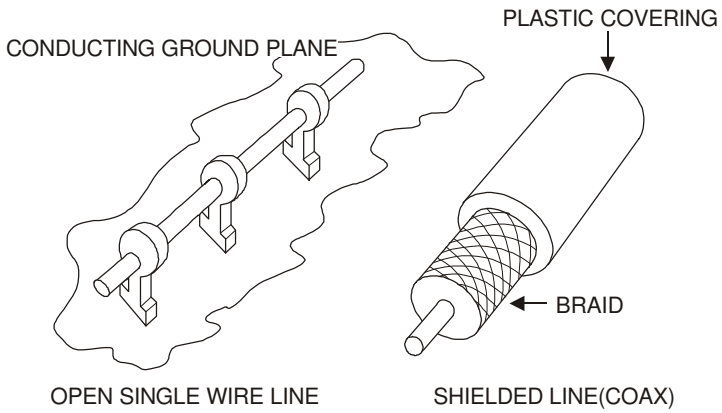
Transmission lines are classified according to construction and length, and fall into two main categories: balanced line and unbalanced line. The terms balanced and unbalanced describe the relationship between transmission line conductors and the Earth. Transmission lines may be classified as resonant or nonresonant lines, each of which may have advantages over the other under a given set of circumstances.

Balanced Line. A balanced line is composed of two identical conductors, usually circular wires, separated by air or an insulating material (dielectric). The voltages between each conductor and ground produced by an RF wave as it moves down a balanced line,

are equal and opposite (i.e. at the moment one of the conductors supports a positive voltage with respect to ground, the other supports a negative voltage of equal magnitude). Some balanced lines carry a third conductor in the form of a braided shield, which acts as ground. Conductor spacings up to several centimeters are commonly used. Figure 3-1 shows balanced and unbalanced lines.



BALANCED TRANSMISSION LINES



UNBALANCED TRANSMISSION LINES

Figure 3-1. Balanced and Unbalanced Transmission Lines.

Unbalanced Line. The unbalanced line is usually open single-wire line or coaxial cable. It is one-half of a balanced line.

Nonresonant Line. A nonresonant line is a line that has no standing waves of current and voltage. It is either infinitely long or is terminated in its characteristic impedance. Because there are no reflections, all of the energy passed along the line is absorbed by the load (except for the small amount of energy dissipated by the line).

Resonant Line. A resonant transmission line has standing waves of current and voltage. The line is of finite length and is not terminated in its characteristic impedance. Reflections are present. A resonant line, like a tuned circuit, is resonant at some particular frequency. The resonant line will present to its source of energy a high or a low resistive impedance at multiples of a quarter-wavelength. Whether the impedance is high or low at these points depends on whether the line is short- or open-circuited at the output end. At points that are not exact multiples of a quarter-wavelength, the line acts as a capacitor or an inductor.

MINIMIZING ENERGY LOSS

To communicate with minimal energy loss, elements such as impedance matching and attenuation (line losses) must be considered.

Impedance

Currents and waves cannot move from place to place without some dissipation; their flow is impeded. Impedance describes the nature and size of whatever impedes their flow. Impedance is an important consideration in selecting the proper transmission line.

A radio wave consists of electric and magnetic fields arranged perpendicularly to each other and to the direction the wave travels. The impedance associated with this wave is the ratio of the potential difference (voltage) to the current (amperage) at a given point along a transmission line. The following formula illustrates this.

$$\frac{\text{Voltage}}{\text{Current}} = \text{Impedance}$$

In transmission lines, because of the length-frequency relationship, the characteristic impedance is more often discussed in terms of capacitance and inductance. In conventional circuits that contain inductors and capacitors, the inductance and capacitance are present in definite lumps. In an RF transmission line, however, these quantities are distributed throughout the entire line and cannot be separated from each other.

If a transmitter is connected to a transmission line that is terminated in a load whose impedance is different from that of the line, only a portion of the available energy will be accepted by the load antenna, and the remainder will be reflected back down the line in the direction of the transmitter. The energy is actually traveling in both directions along the line.

If a transmitter is connected to a transmission line terminated in a load whose impedance exactly equals the impedance of the line, the line will absorb all of the energy except for that lost in the resistive and dielectric losses of the line. Current flowing through the line will be uniformly distributed along its length, and the voltage between the conductors on the line will be equal at all points. When this condition exists, the line is said to be perfectly matched and carries only a forward or incident wave. If the impedance of the transmission line and the load also equal the internal impedance (output impedance) of the transmitter, a maximum transfer of

energy (lowest system loss) is achieved (i.e., the transmitter or receiver, transmission line, and antenna are all the same impedance), and the best possible transfer of signal energy will occur.

Optimizing Line Length

When it is necessary to use a transmission line whose impedance is significantly different from that of the load, it is possible to make good use of standing waves and the repetitive impedance variations along the line to match the antenna to the transmitter or the receiver to the antenna by cutting the line to a specific length. An example is when the only available equipment consists of a 300-ohm twin-lead transmission line; a 50-ohm half-wave dipole antenna; and a 50-ohm internal impedance transceiver. (Note: The internal impedance of most USMC radios is 50 ohms). Ordinarily, this impedance combination would result in lost energy that could affect the quality of communications. However, if a single frequency is used to communicate, the length between the antenna and the receiver can be matched. This occurs because the impedance of the receiver is repeated at intervals of a half-wavelength along the line.

For end-fed, long-wire antennas, a similar impedance match can be made by feeding the long wire with a quarter-wavelength piece of wire that is connected to the transmitter on one end and to the end of the long wire on the other. The quarter-wavelength section doesn't need to be a separate piece of wire. For a 2-wavelength, long-wire antenna, for example, the wire can be cut to 2 1/4 wavelengths. The entire quarter-wavelength section then becomes the transmission line between the radio and the antenna.

Attenuation

Transmission lines do not transfer all of the energy applied at one end of the line to the opposite end. Attenuation is energy that is lost when converted into heart, partially due to conductor (wire) resistance. More energy is lost due to the insulation material used to space the conductors (dielectric loss). Some insulating materials (e.g., Teflon) have extremely low loss while others (e.g., rubber or wood) have relatively high loss, especially at frequencies above about 30 MHz. Old, dry wood (especially redwood) may be boiled in paraffin or bee's wax to make a fairly good insulator at frequencies up to about 200 MHz. Polyethylene, a common insulation material used in coaxial cables, has an average loss of about twice that of Teflon in the 100-MHz range for cables having a diameter of less than about one centimeter. Dry air is a better insulator than most solid, liquid, or flexible materials. Some inert gases (e.g., nitrogen, helium, and argon) are superior to air and are often used under pressure to fill coaxial cables used with high-powered transmitters.

Since attenuation results from conductor resistance and dielectric loss, transmission lines using large diameter conductors lose less energy than cables having small diameter conductors. Also, transmission lines having a large spacing between conductors (high impedance) will lose less energy than those with a smaller spacing (lower impedance) since they carry smaller currents and there is less energy lost in conductor resistance. Thus, 300-ohm twin-lead has less loss than coaxial cable at most frequencies. Among coaxial cables, the larger the diameter, the lower the loss, assuming the same insulator is used. It is also true that coaxial cable, which has an impedance of 75 ohm, has slightly lower loss than 50-ohm cable, when both cables have about the same diameter. When there is a choice, it is best to use the largest available transmission line which matches the impedance of both the antenna and transmitter.

MAKING THE BEST USE OF AVAILABLE TRANSMISSION LINES

It is often necessary to feed a balanced antenna (e.g., horizontal dipole) with coaxial cable. While this is not considered good practice, it will perform satisfactorily under most conditions. When coaxial cable is used for this purpose, it should run perpendicular to the dipole wires for a distance greater than one-half of the length of the dipole. This will help to prevent unwanted RF power from being induced on the outside shield of the cable. It is also advisable to make sure that the total length of the coaxial cable and one side of the antenna is not equal to a half-wavelength or any multiple thereof. This will prevent the outside conductor from becoming resonant and acting as a radiating part of the antenna. The same precaution should be taken with twin-lead transmission line.

Occasionally, it may also be necessary to feed an unbalanced antenna (e.g., a whip with twin-lead or balanced line). Again this is not considered good practice, but the bad effects can be minimized if care is taken. If the transmitter has a balanced output circuit, little difficulty will be experienced. However if the output is unbalanced, the hot terminal or coaxial center at the transmitter output must be connected to the same wire of the twin-lead as is the vertical whip at the other end of the twin-lead. This ensures that the ground side of the transmitter output is connected to the side of the twin-lead that goes to the ground side of the unbalanced antenna.

If the twin-lead is reversed and the antenna ground terminal is connected to the hot terminal of the transmitter, a large portion of the transmitter output may be wasted, making communications either difficult or impossible. Twin-lead of the type commonly used with television sets usually has one tinned and one bare copper conductor. This color coding readily permits correct connection of the transmitter to the antenna. It is also advisable to make the length of

the twin-lead equal to a half-wavelength or any multiple of a half-wavelength. When possible, the twin-lead should be twisted so that it forms a long helix with about one twist every thirty centimeters, or so. Twisting helps to prevent transmission line radiation and reduces noise pickup when receiving.

Twin-Lead Limitations

It is generally best not to use twin-lead or balanced line at frequencies higher than about 200 MHz for three reasons.

First, the spacing between the two wires becomes sufficiently large in terms of a wavelength that radiation from the line occurs. When lengths over 30 meters are employed, this radiation may represent a significant loss of energy.

Second, if the twin-lead or balanced lines must come in close contact (less than 2 or 3 cm) with metal, masonry, or wood surfaces, additional losses will be encountered due to the substantial impedance change which takes place along the section of the line next to the surface. This mismatch loss becomes apparent at frequencies above 200 MHz because the length of the section affected becomes a substantial portion of a wavelength long. At lower frequencies, the section of line involved is too short to be seriously affected.

Third, twin-lead picks up more locally generated interference than coaxial cable since the outer conductor of the coaxial cable acts as a shield for the center conductor. Radiation and noise pickup by twin-lead can be partially prevented by twisting it once every 20 or 30 centimeters.

When using common, TV twin-lead (300 ohm), preference should be given to the deep brown rather than the light, colorless variety. The darker colored twin-lead withstands the effects of sunlight and

moisture after prolonged outdoor exposure much better than the clear type. The clear, colorless, twin-lead tends to crack after a few months exposure to the Sun. It also begins to absorb moisture which greatly increases energy loss.

Directly Connecting the Transceiver and Antenna

In many instances the transmitter or receiver may be connected directly to the antenna wire without using a transmission line. This is particularly true with indoor antennas in the HF range and with many VHF whip antennas designed for use with manpack transceivers.

When a direct connection is made between a transmitter and the antenna at frequencies below 30 MHz or where the length of the antenna wire is much shorter than 0.25 λ, the output circuit of the transmitter usually contains a matching device which may be used to tune the antenna efficiently to resonance. This tuning actually matches the impedance of the antenna to the output impedance of the transmitter.

When a VHF transceiver is designed to connect directly to a short whip or self-contained, collapsible rod, the output circuit is usually designed to accommodate the range of impedances likely to be encountered at the base of the whip or rod.

The efficiency of these devices is usually low since the ground return circuit for the antenna may range from nothing more than the case of the transmitter to the hand and body of an individual holding the device. The impedance of the antenna may vary with frequency over a range of 5 to 1 or greater. Thus, antenna efficiencies of from 25 to 50 percent are not uncommon with such devices.

BALUNS

There are times when a balanced antenna must be used with a transmitter or receiver which has an unbalanced output or input circuit. While it is possible to make a direct connection between balanced and unbalanced devices, it is certainly not good practice. A balun can be used to transform energy from balanced to unbalanced devices and vice versa.

The word balun comes from balanced to unbalanced transformer. Many balun types are easily constructed in the field. Using them can often make the difference between marginal communications and completely solid contact. This may be especially true in the receiving case where a balun can result in a substantial reduction in the amount of manmade noise and interference received by a poorly balanced antenna system. The balun is usually placed at the antenna terminals so that a coaxial transmission line can be used. However, it is possible to feed a balanced antenna with twin-lead or any kind of balanced line, and the balun is placed near the transmitter or receiver terminals (see figs. 3-2 and 3-3).

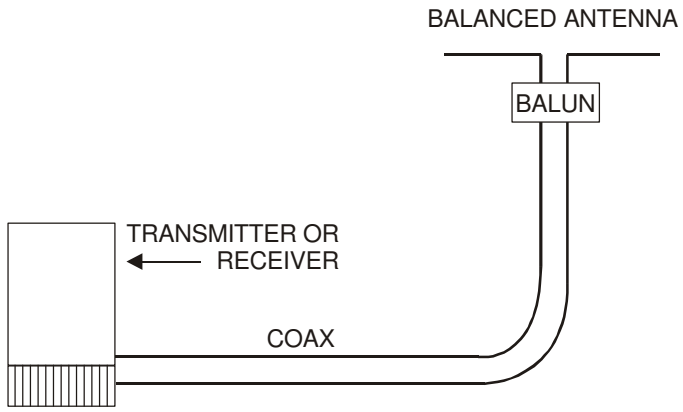


Figure 3-2. A Balun Placed at the Antenna.

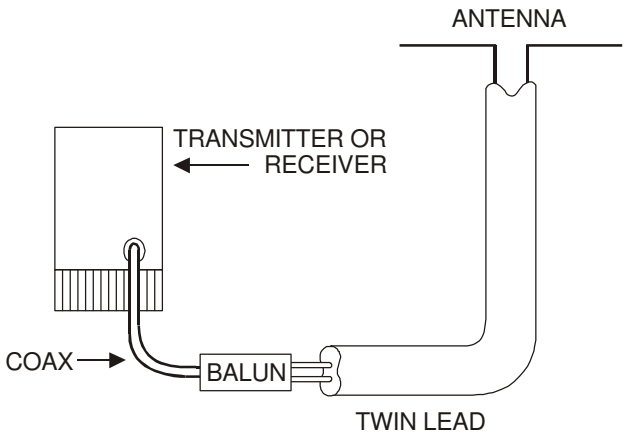

Figure 3-3. Balun Placed at the Transmitter or Receiver.

Cable Connectors

Cable connector fittings are available for all standard transmission lines. Although it takes some time to prepare the cable ends and solder the fittings on, it may be well worth it later if rapid assembly or disassembly of a communications system is necessary.

Balanced Antenna

It is highly desirable to use a receiving antenna which is balanced with respect to ground. This insures the antenna's insensitivity to locally generated noise. Balancing only the receiving antenna is not enough. The entire receiving system must be balanced to successfully reject noise. The antenna should be connected to its receiver so as not to disrupt the antenna's balance. Receivers are supplied with either balanced or unbalanced antenna terminals, and sometimes both.

(reverse blank)

Chapter 4

HF Antenna Selection

The HF portion of the radio spectrum is very important to communications. Radio waves in the 3 to 30 MHz frequency range are the only ones that are capable of being reflected or returned to Earth by the ionosphere with predictable regularity. To optimize the probability of a successful sky wave communications link, select the frequency and take-off angle that is most appropriate for the time of day transmission is to take place.

Merely selecting an antenna that radiates at a high elevation angle is not enough to ensure optimum communications. Various large conducting objects, in particular the Earth's surface, will modify an antenna's radiation pattern. Sometimes, nearby scattering objects may modify the antenna's pattern favorably by concentrating more power toward the receiving antenna. Often, the pattern alteration results in less signal transmitted toward the receiver.

When selecting an antenna site, the operator should avoid as many scattering objects as possible. How the Earth's surface affects the radiation pattern depends on the antenna's height. The optimum height above electrical ground is about 0.4 λ at the transmission frequency. However, the exact height is not critical.

Although NVIS is the chief mode of short-haul HF propagation, the ground wave and direction (LOS) modes are also useful over short paths. How far a ground wave is useful depends on the electrical conductivity of the terrain or body of water over which it travels. The direct wave is useful only to the radio horizon, which extends slightly beyond the visual horizon.

ANTENNA SELECTION PROCEDURE

Selecting the right antenna for an HF radio circuit is very important. When selecting an HF antenna, first consider the type of propagation. Ground wave propagation requires low take-off angle and vertically polarized antennas. The whip antenna included with all radio sets provides good omnidirectional ground wave radiation.

If a directional antenna is needed, select one with good, low-angle vertical radiation. An example is an AN/MRC-138 with its component 32-foot whip set up on a 200-mile circuit. With the radiation characteristics of the whip antenna, the radiated power of the transmitter or whip could be 300 watts for the take-off angle required for a 200-mile circuit.

If a 35-foot half-wave horizontal dipole is used instead of the whip, the radiated power would be 5,000 watts. By using the dipole instead of the whip, the radiated power is increased more than 16 times. A circuit with 5,000 watts of radiated power produces a better signal than a 300-watt circuit using the same frequency.

Selecting an antenna for sky wave propagation is more complex. First, find the circuit (range) distance so that the required take-off angle can be determined. Table 4-1 gives approximate take-off angles for daytime and nighttime sky wave propagation. A circuit distance of 966 kilometers (600 miles) requires a take-off angle of approximately 25° during the day and 40° at night. Select a high-gain antenna (25° to 40°). If propagation predictions are available, skip this step, since the predictions will probably give the take-off angles required.

Next, determine the required coverage. A radio circuit with mobile (vehicular) stations or several stations at different directions from the transmitter requires an omnidirectional antenna. A point-to-point

circuit uses either a bidirectional or a directional antenna. Normally, the receiving station locations dictate this choice (see table 4-1).

Table 4-1. Take-Off Angle vs. Distance.

Take-off Angle (Degrees)	Distance			
	F2 Region Daytime		F2 Region Nighttime	
	kilometers	miles	kilometers	miles
0	3220	2000	4508	2800
5	2415	1500	3703	2300
10	1932	1200	2898	1800
15	1450	900	2254	1400
20	1127	700	1771	1100
25	966	600	1610	1000
30	725	450	1328	825
35	644	400	1127	700
40	564	350	966	600
45	443	275	805	500
50	403	250	685	425
60	258	160	443	275
70	153	95	290	180
80	80	50	145	90
90	0	0	0	0

Before selecting a specific antenna, examine the available construction materials. At least two supports are needed to erect a horizontal dipole, with a third support in the middle for frequencies of 5 MHz or less. If these supports or other items to use as supports are unavailable, the dipole cannot be constructed, and another antenna should be selected. Examine the proposed antenna site to determine if the antenna will fit. If not, select a different antenna.

The site is another consideration. Usually, the tactical situation determines the position of the communications antennas. The ideal setting would be a clear, flat area (i.e., no trees, buildings, fences, power lines, or mountains). Unfortunately, an ideal location is seldom available. Choose the clearest, flatest area possible. If the proposed site is obstructed, try to maintain the horizontal distance listed in table 4-2. Often, an antenna must be constructed on irregular sites. This does not mean that the antenna will not work. It means that the site will affect the antenna's pattern and function.

Table 4-2. Assuming a 30-Foot Antenna and 75-Foot Trees

Take-Off Angle (Degrees)	Required Horizontal Distance from Trees	
0	18	kilometers
5	1932	meters
10	966	meters
15	644	meters
20	483	meters
25	370	meters
30	298	meters
35	241	meters
40	201	meters
45	169	meters
50	145	meters
60	105	meters
70	64	meters
80	32	meters
90	0	meters

After selecting the antenna, determine how to feed the power from the radio to the antenna (fig. 4-1). Most tactical antennas are fed with coaxial cable (RG-213). Coaxial cable is a reasonable compromise of efficiency, convenience, and durability. Issued antennas include the necessary connectors for coaxial cable or for direct connection to the radio.

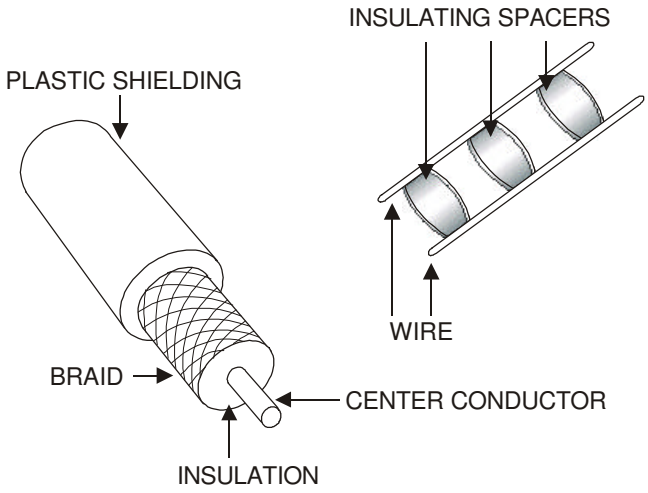

Figure 4-1. Antenna Feed Lines.

Problems may arise in connecting field expedient antennas. The horizontal half-wave dipole uses a balanced transmission line (open-wire). Coaxial cable can be used, but it may cause unwanted RF current.

A balun prevents unwanted RF current flow, which causes a radio to be hot and shock the operator. Install the balun at the dipole feed point (center) to prevent unwanted RF current flow on the coaxial cable. If a balun is unavailable, use the coaxial cable that feeds the

antenna as a choke (see fig. 4-2). Connect the cable's center wire to one leg of the dipole and the cable braid to the other antenna leg. Form the coaxial cable into a 6-inch coil (consisting of ten turns), and tape it to the antenna under the insulator for support.

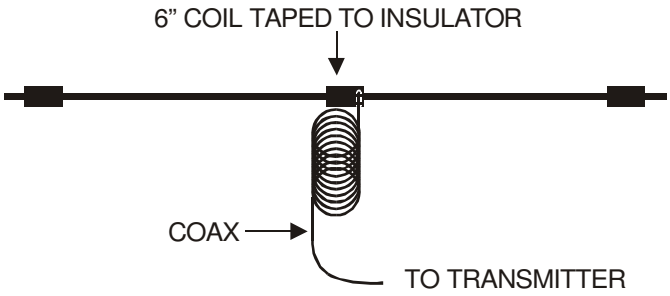

Figure 4-2. Coax RF Current Choke.

DETERMINING ANTENNA GAIN

Determine antenna gain at a specific take-off angle from the vertical radiation pattern. Figure 4-3 shows the vertical antenna pattern for the 32-foot vertical whip. The numbers along the outer ring (90°, 80°, 70°) represent the angle above the Earth; 90° would be straight up, and 0° would be along the ground. Along the bottom of the pattern are numbers from -10 (at the center) to +15 (at the edges). These numbers represent the gain in decibels over an isotropic radiator (dBi).

To find the antenna gain at a particular frequency and take-off angle, locate the desired take-off angle on the plot. Follow that line toward the center of the plot to the pattern of the desired frequency. Drop down and read the gain from the bottom scale. If the gain of a 32-foot vertical whip at 9 MHz and 20° take-off angle is desired, locate 20° along the outer scale. Follow this line to the 9-MHz

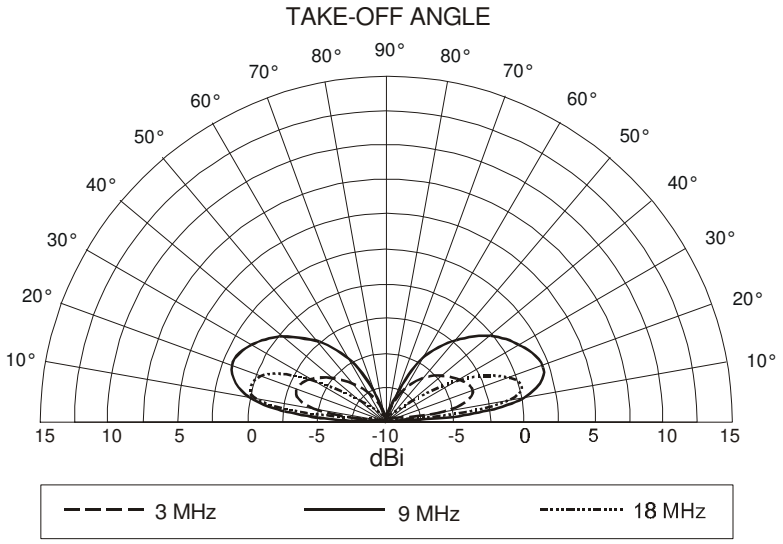

Figure 4-3. 32-Foot Vertical Whip, Vertical Pattern.

pattern line. Move down to the bottom scale. The gain is a little less than 2.5 dBi (the line between 0 and 5 dBi). The gain of the 32-foot vertical whip at 9 MHz and 20° is 2 dBi.

Once the antenna's overall characteristics are determined, use the antenna selection matrix (table 4-3 on page 4-8) to find the specific antenna for a circuit. If the proposed circuit requires a short-range, omnidirectional, wideband antenna, the selection matrix shows that the only antenna that meets all the criteria is the AS-2259/GR.

If the circuit requires a medium-range directional antenna, several antennas could be used (e.g., long wire, sloping vee, or vertical half-rhombic). The antenna choice depends on available installation space, available components, and required highest gain take-off angle. For a required take-off angle of 25° at a frequency of 9 MHz,

the 100-foot vertical half-rhombic antenna is the best choice because it provides the highest gain at the required take-off angle.

Table 4-3. Antenna Selection Matrix.

	Use				Directivity			Polar-ization		Band-width	
		Sky Wave									
	Ground Wave	Short (500 Miles)	Medium (500 to 1200 Miles)	Long (1200 Miles)	Omnidirectional	Bidirectional	Directional	Horizontal	Vertical	Wide	Narrow

ANTENNA TYPES

The AS-2259/GR, vertical whip, half-wave dipole, inverted vee, long wire, inverted L, sloping vee, sloping wire, and vertical half-rhombic antennas are described and illustrated.

AS-2259/GR

The AS-2259/GR antenna (fig. 4-4) provides NVIS propagation for short-range radio circuits. It consists of two crossed sloping dipoles positioned at right angles to each other and is supported at the center by a 15-foot mast. In use, the dipole's components provide guying support for the mast. Characteristics are—

Frequency range:	**2 to 30 MHz**
Polarization:	**Horizontal and vertical simultaneously**
Power capability:	**1,000 watts**
Radiation pattern	
Azimuthal (bearing):	**Omnidirectional**
Vertical (take-off angle):	**See figure 4-5 on page 4-10**

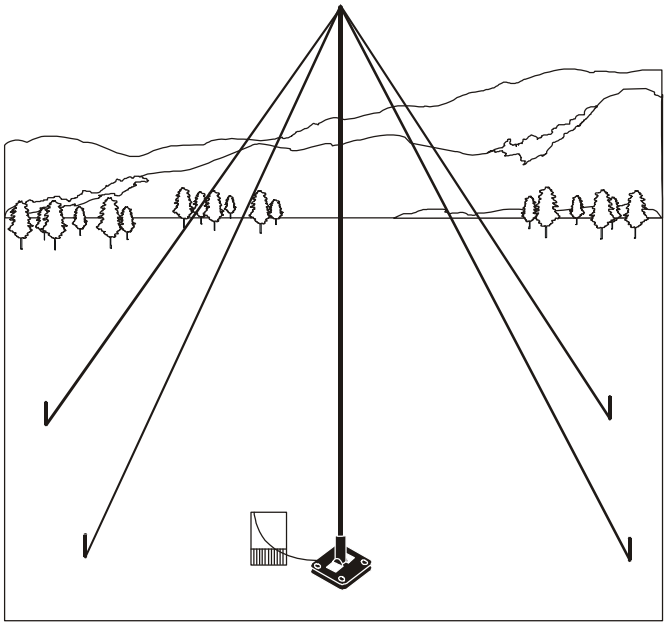

Figure 4-4. AS-2259/GR.

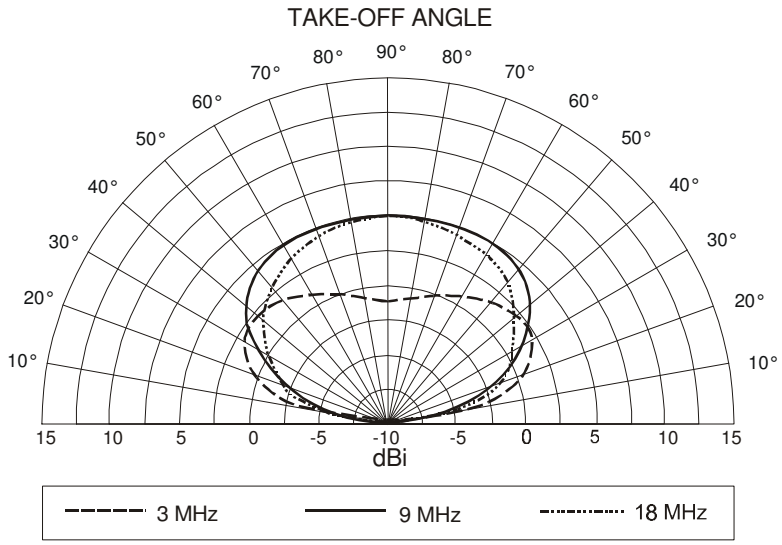

Figure 4-5. AS-2259 Vertical Radiation Pattern.

Vertical Whip

The vertical whip is a component of all Marine Corps radio sets (see fig. 4-6). It is available and easy to use on almost all radio circuits; however, it is probably the worst antenna to use on sky wave circuits. Unless the radio circuit involves omnidirectional ground wave propagation, any other antenna would provide better communications. For example, vertical whips are often used for long-range point-to-point circuits with marginal success. Since the circuit is point-to-point, there is no need to radiate energy in all directions. Radiation in directions other than at the distant station is wasted and serves no useful purpose. Concentrating the omnidirectional radiation at the distant station produces a better received signal and reduces interference around the transmitting antenna. Concentrate radiation in a single direction with a directional antenna. Figures

4-7 on page 4-12, 4-8 on page 4-13, and 4-3 on page 4-7 illustrate various vertical whip antenna patterns.

Characteristics are—

Frequency range:	**2 to 30 MHz**
Polarization:	**Vertical**
Power capability:	**Matched to specific radio**
Radiation pattern	
Azimuthal (bearing):	**Omnidirectional**
Vertical (take-off angle):	**See figures 4-7 on page 4-12, 4-8 on page 4-13, and 4-3 on page 4-7**

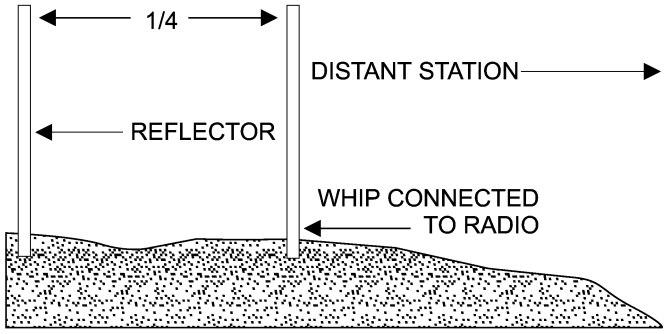

Figure 4-6. Vertical Whip with Reflector.

If a vertical whip must be used, there are several techniques to improve the antenna radiation. If the antenna is mounted directly to the radio, ground the radio. If the antenna is remoted from the radio ground the antenna base plate. A 6-foot ground rod is preferable for both. Ground radials (wires spread out like wheel spokes with the antenna at the center) may improve the antenna radiation. Connect these radials to the ground rod directly beneath the antenna.

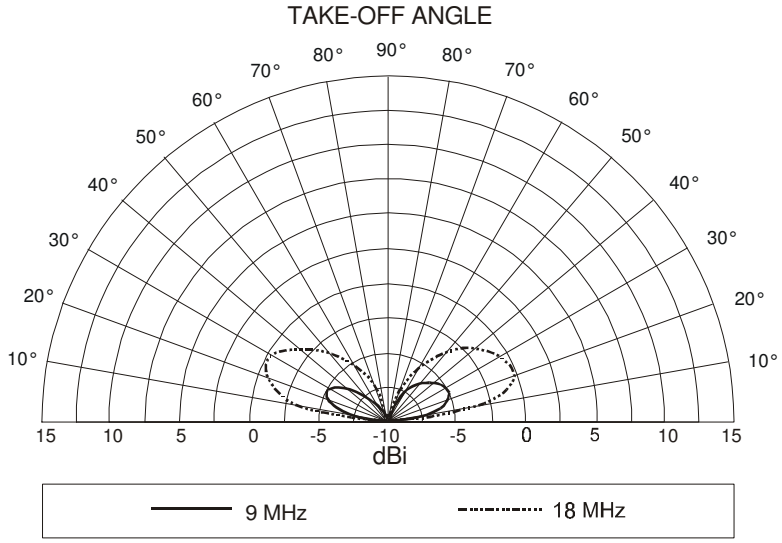

Figure 4-7. 10-Foot Vertical Whip (Vertical Pattern).

A ground radial system can be constructed easily from field telephone wire (WDl/TT) and can be kept with the radio. Cut the field wire into twenty 45-foot lengths, and remove 6 inches of insulation from one end. Using twine or a clamp, bundle together the uninsulated (bare) ends. Attach a 2-foot length of thick wire to the bare ends so that the thick wire extends about one foot beyond the wire bundle. Solder the wire bundle to ensure good electrical contact. In use, the thick wire extending from the bundle connects the radials to a ground rod. The radials are then spread out like wheel spokes with the vertical whip at the center. Radio operators should experiment with different radial systems to determine which one provides the best connectivity.

A reflector placed approximately one-quarter wavelength behind a vertical whip may also improve the whip's performance. A reflector

is a vertical wire, metallic pole, or another whip that is insulated from the ground. It is placed so that the reflector, the whip, and the distant station are on a straight line. The reflector will reflect radio energy striking it and cause the energy to travel toward the distant station, increasing the total energy radiated in the desired direction. To work properly, the reflector must be longer than the whip. If the reflector is shorter, it will act as a director, directing the radio signal away from the distant station. A reflector is longer and is placed behind the whip; a director is shorter and is placed between the whip and the distant station. Adjust the position of the reflector while listening to the distant station until the strongest signal is received.

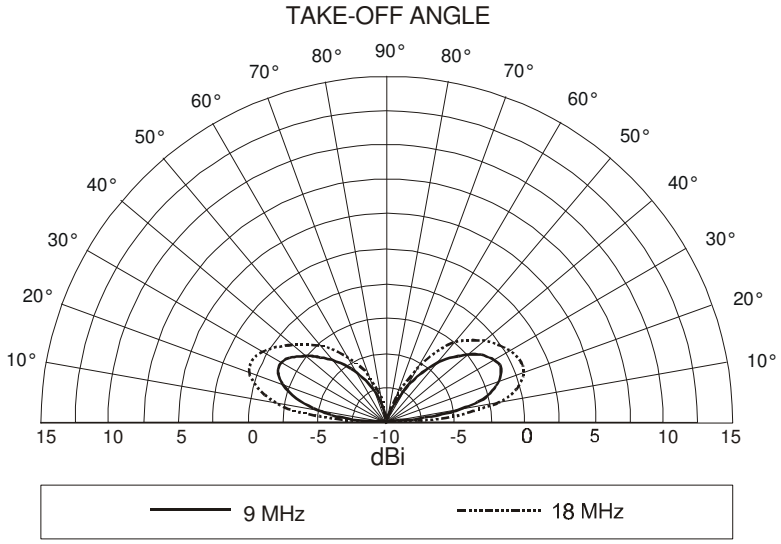

Figure 4-8. 15-Foot Vertical Whip (Vertical Pattern).

The length of a vertical whip antenna is calculated from the following formula:

$$\text{Length in feet} = \frac{234}{\text{Frequency in MHz}}$$

For WD-l/TT

$$\text{Length in feet} = \frac{225.50}{\text{Frequency in MHz}}$$

Half-Wave Dipole

The horizontal half-wave dipole (doublet) antenna is used on short- and medium-length sky wave paths (up to approximately 1,200 miles). Since it is relatively easy to design and construct, the doublet is the most commonly used field expedient wire antenna. It is a very versatile antenna; by adjusting the antenna's height above ground, the maximum gain can vary from medium take-off angles (for medium path-length circuits) to high take-off angles (for short path-length circuits). When the antenna is constructed for medium take-off angle gain (a height of approximately one-half wavelength), the doublet is a bidirectional antenna (i.e., the maximum gain is at right angles to the wire). This is the broadside pattern normally associated with a half-wave dipole antenna. Format A in figure 4-9 shows this pattern in polar plot format.

Format B shows the radiation off the ends of the wire. It is easily seen by comparing with format A that for maximum gain, a doublet one-half wavelength above ground should be constructed so that the side of the antenna points in the direction of the distant station. If the antenna is lowered to only one-quarter wavelength above ground, format C results. This lower antenna height produces

maximum gain at high take-off angles. In format D, the radiation off the ends of the doublet also has maximum gain at high take-off angles. This means that for short path-length circuits, which require high take-off angles, a doublet antenna one-quarter wavelength above ground produces almost omnidirectional coverage.

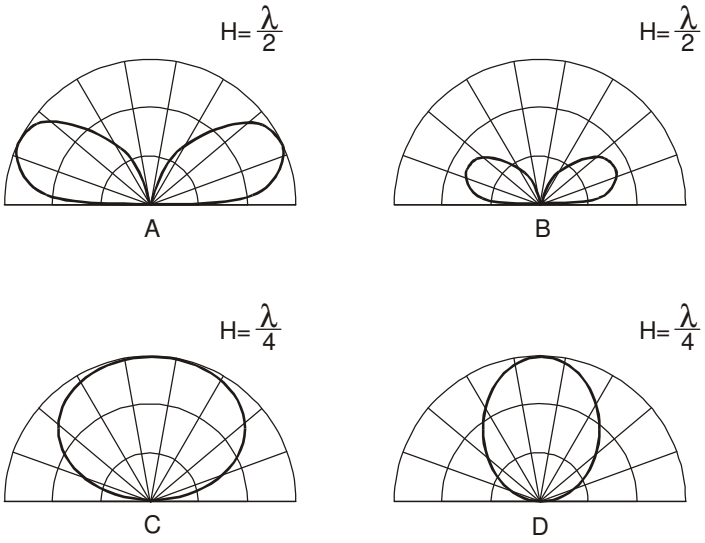

Figure 4-9. Illustrative Doublet Antenna Patterns.

The vertical plots included for half-wave dipole antennas are given for heights from 8 to 12 meters. The plot for 8 meters shows that for 3 and 9 MHz the antenna has high-angle radiation. At those frequencies the antenna is close to ground (compared to a half-wavelength). The pattern for 18 MHz shows the characteristic bidirectional pattern since 8 meters is a half-wave at 18 MHz.

The half-wave dipole is a balanced resonant antenna (see fig. 4-10 on page 4-16). It produces its maximum gain for a very narrow

range of frequencies, normally 2 percent above or below the design frequency. Since frequency assignments are usually several megahertz apart, it is necessary to construct a separate dipole for each frequency assigned (see figs. 4-11 and 4-12 on page 4-17, and 4-13 on page 4-19). If space and other resources are unavailable to erect separate dipoles, three or four dipoles can be combined to occupy the space normally required for one.

Each wire is a half-wavelength for an assigned frequency. The separate dipoles are connected to the same center insulator, or preferably a balun, and are fed by a single coaxial cable. When the antenna is

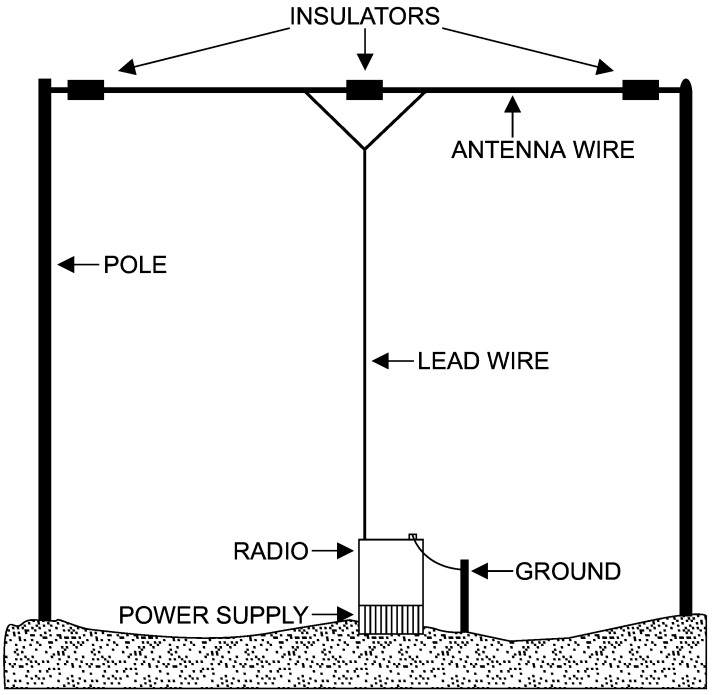

Figure 4-10. Half-Wave Dipole Antenna.

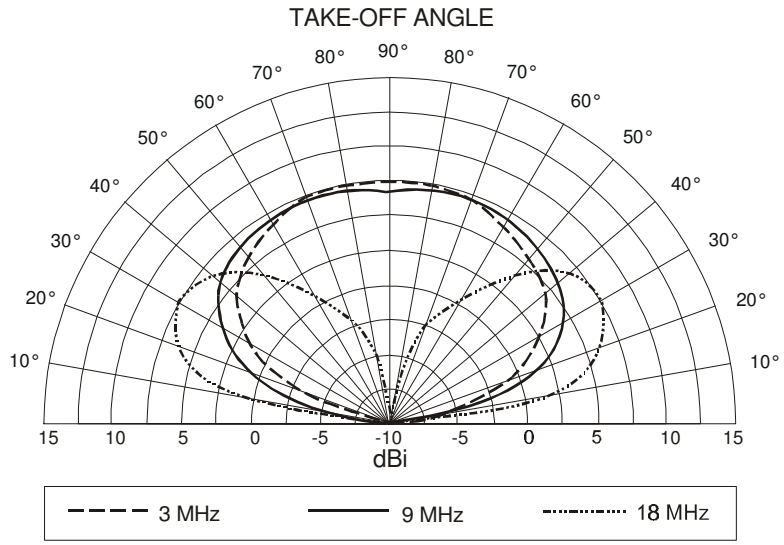

Figure 4-11. 8-Meter Half-Wave Dipole (Vertical Pattern).

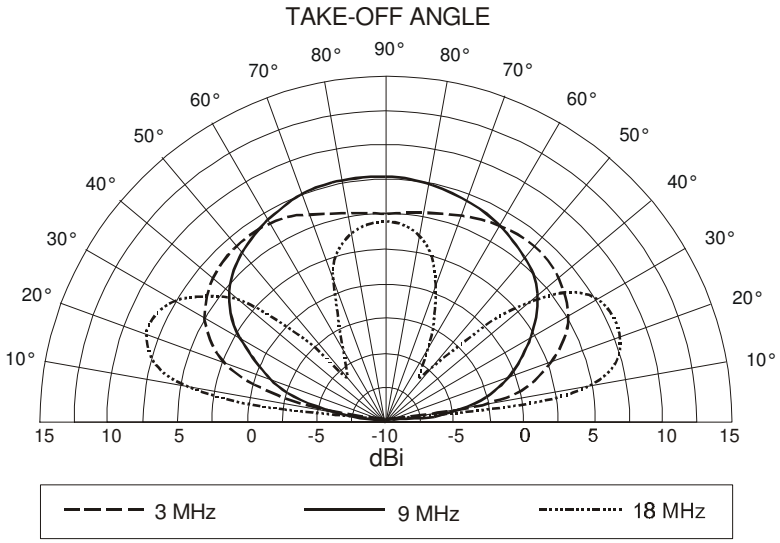

Figure 4-12. 10-Meter Half-Wave Dipole (Vertical Pattern).

fed with an assigned frequency, the doublet cut for that frequency will radiate the energy. Up to four separate dipoles can be combined in this manner. When constructing this antenna, examine the individual frequency assignments to determine if one frequency is three times as large as another. If this relationship exists between two frequencies, one dipole cut in length for the lower of the two frequencies will work well for both frequencies.

The length of a half-wave dipole is calculated from the following relationship:

$$\text{Dipole length} = \frac{\text{142 meters}}{\text{Frequency in MHz}} \quad \text{or} \quad \frac{\text{468 feet}}{\text{Frequency in MHz}}$$

The height of a half-wave dipole is figured using—

$$\text{Height X/4} = \frac{\text{75 meters}}{\text{Frequency in MHz}} \quad \text{or} \quad \frac{\text{246 feet}}{\text{Frequency in MHz}}$$

$$\text{Height X/2} = \frac{\text{150 meters}}{\text{Frequency in MHz}} \quad \text{or} \quad \frac{\text{492 feet}}{\text{Frequency in MHz}}$$

Use the right relationship for the right purpose. If the height relationship is used for the dipole length, the antenna will be too long and will not work properly. Characteristics are—

Frequency range:	± 2% of design frequency
Polarization:	Horizontal
Power capability:	1,000 watts
Radiation Pattern	
Azimuthal (bearing):	Bidirectional λ/2 high basically omnidirectional at λ/4 high
Vertical (takeoff angle):	See figures 4-11 and 4-12 on page 4-17, and 4-13 on page 4-19

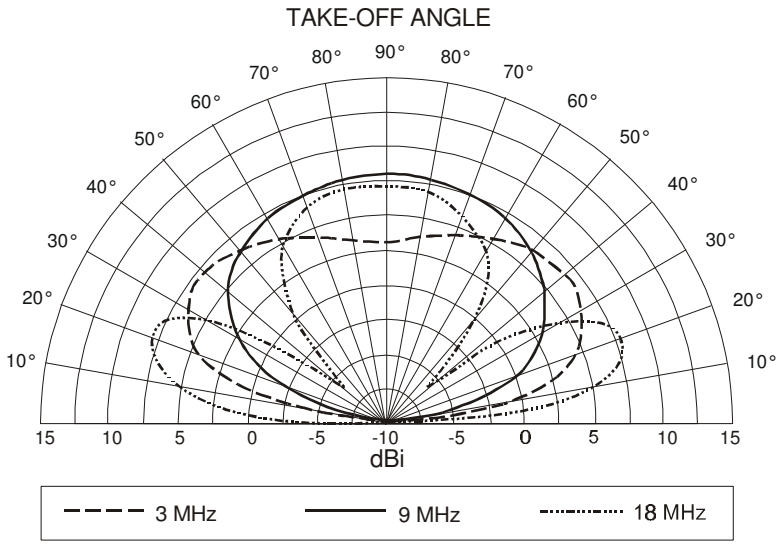

Figure 4-13. 12-Meter Half-Wave Dipole (Vertical Pattern).

Inverted Vee

The inverted vee, or drooping dipole, is similar to a dipole but uses only a single center support (see fig. 4-14 on page 4-20). Like a dipole, it is designed and cut for a specific frequency and has a bandwidth of 2 percent above or below the design frequency. Because of the inclined sides, the inverted vee antenna produces a combination of horizontal and vertical radiation—vertical off the ends and horizontal broadside to the antenna. All the construction factors for a dipole also apply for the inverted vee. The inverted vee has less gain than a dipole, but using only a single support could make this antenna the preferred antenna in some tactical situations (see fig. 4-15 on page 4-21).

Characteristics are—

Frequency range:	**± 2% of design frequency**
Polarization:	**Horizontal**
Power capability:	**1,000 watts**
Radiation pattern	
Azimuthal (bearing):	**Basically omnidirectional with combination polarization**
Vertical (take-off angle):	**See figure 4-15**

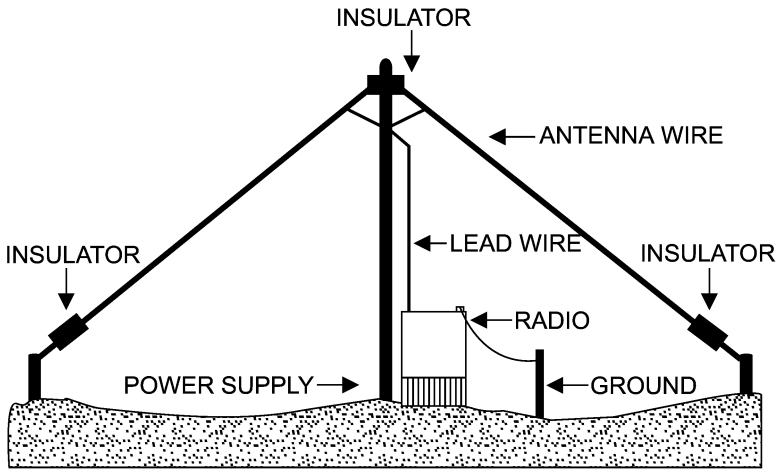

Figure 4-14. Inverted Vee Antenna.

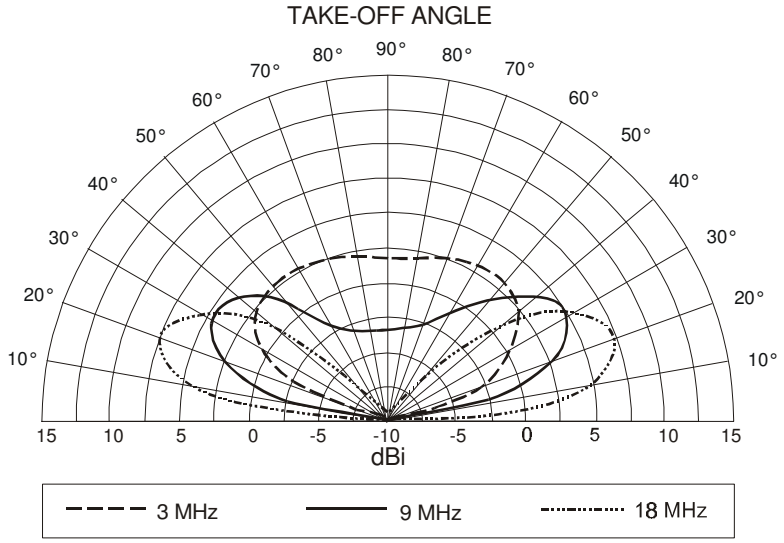

Figure 4-15. Inverted Vee (Vertical Pattern).

Long Wire

A long wire antenna is one that is long compared to a wavelength (see fig. 4-16 on page 4-22). A minimum length is one-half wavelength. However, antennas that are at least several wavelengths long are needed to obtain good gain and directional characteristics. Constructing long wire antennas is simple, and there are no critical dimensions or adjustments. A long wire antenna will accept power

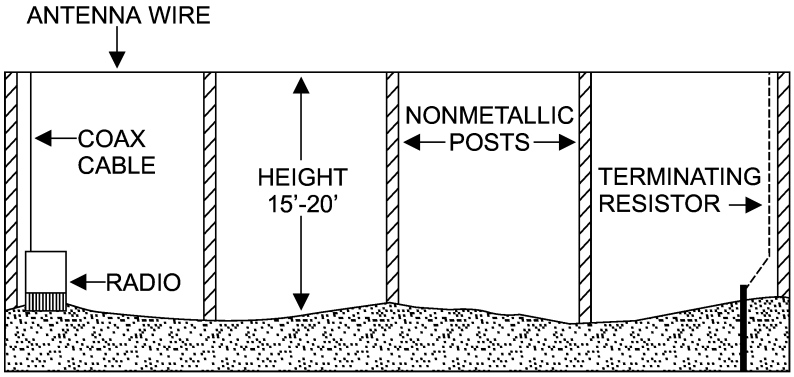

Figure 4-16. Long Wire Antenna.

and radiate it well on any frequency for which its overall length is not less than one-half wavelength.

The gain and take-off angle of a long wire antenna depend on the antenna's length. The longer the antenna, the more gain, and the lower the take-off angle. Gain has a simple relationship to length; however, take-off angle is a bit more complicated. A long wire antenna radiates a cone of energy around the tie wire, much like a funnel with the antenna wire passing through the funnel opening. The narrow part of the funnel would be the feed point, and the open part would be toward the distant station. If the funnel were cut in half, the resulting half cone would represent the pattern of the antenna. As the antenna is lengthened, the cone of radiation (funnel) moves closer and closer to the wire. Figure 4-17 shows pattern

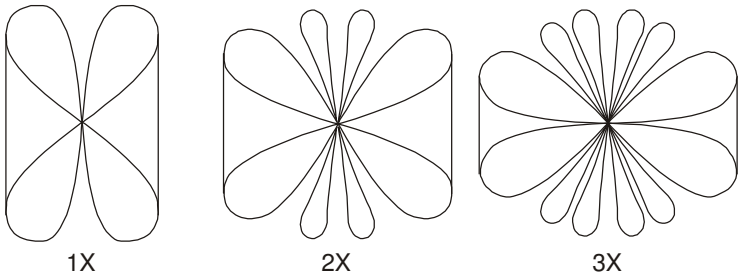

Figure 4-17. Long Wire Radiation Patterns.

changes as the wire is lengthened. The patterns represent a view from directly below the antenna.

In the three-wavelength pattern, for very low-angle radiation, position the wire somewhat away from the direction of the distant station so that the main lobe of radiation points at the receiving station. If a higher take-off angle is required, point the wire directly at the distant station. For take-off angles from 5 to 25 feet, the following general off-axis angles will provide satisfactory radiation on toward the distant station (see table 4-4).

Table 4-4. Off-Axis Angle.

Wire Length (Feet)	2	3	4	5	6
Off-Axis Angle (Degrees)	30	20	13	10	10

To make a long wire antenna directional, place a terminating device at the distant station end of the antenna. The terminating device should be a 600-ohm, noninductive resistor capable of absorbing at

least one-half of the transmitter power. Terminating resistors are components of some radio sets but can also be fabricated locally using supply system components (100-watt, 106-ohm resistor).

Constructing a long wire antenna requires only wire, support poles, insulators, and a terminating resistor (if directionality is desired). The only requirement is that the antenna be strung in as straight a line as the situation permits. The antenna is only 15 to 20 feet above ground, so tall support structures are not required. The antenna is normally fed through a coupler that can match the antenna's 600-ohm impedance. Coaxial cable can be used if a 12 to 1 balun is available to convert the coaxial cable 50-ohm impedance to the required 600 ohms. Vertical radiation plots of this antenna are not presented because of the great variation in the pattern as the length changes. For take-off angles between 5 and 25 feet, use the off-axis graph (table 4-4 on page 4-23) and the gain versus length graph (table 4-5) to determine the proper antenna length. Characteristics are—

Frequency range:	2 to 30 MHz
Polarization:	Vertical
Power capability:	1,000 watts
Radiation pattern	
Azimuthal (bearing):	Bidirectional with terminating resistor
Vertical (take-off angle):	Depends on length

Inverted L

The inverted L is a combination antenna made up of a vertical section and a horizontal section (see fig. 4-18). It provides omnidirectional radiation for ground wave propagation from the vertical element and high-angle radiation from the horizontal element for short-range sky wave propagation. The classic inverted L has a quarter-wave vertical section and a half-wave horizontal section

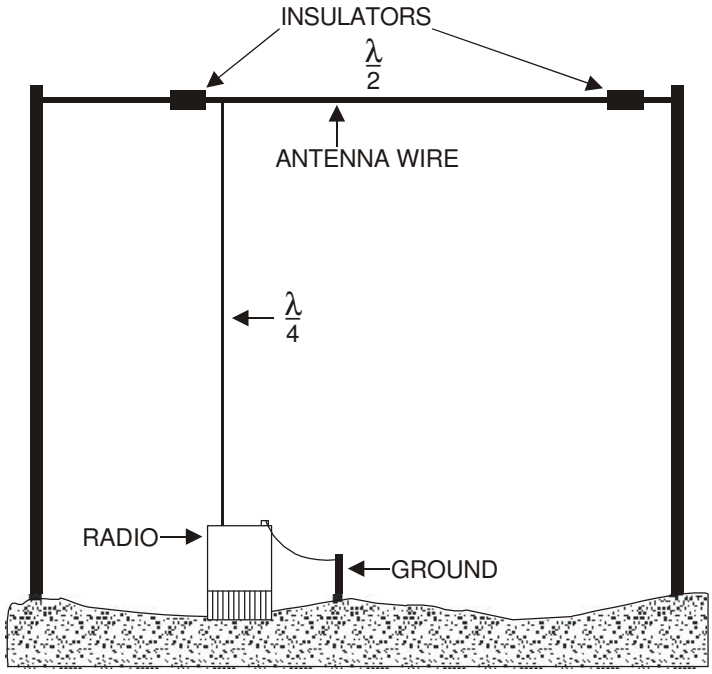

Figure 4-18. Inverted L Antenna.

and is used for a very narrow range of frequencies. By using the antenna couplers that are part of many radio sets, the dimensions of the inverted L can be modified to allow ground wave and short-range sky wave propagation over a range of frequencies. Using a vertical height of 35 to 40 feet, the following horizontal lengths will give reasonable performance for short-range sky wave circuits.

Table 4-5. Gain Versus Length.

Frequency Range (MHz)	2.5 to 4.0	3.5 to 6.0	5.0 to 7.0
Horizontal Length (Feet)	150	100	80

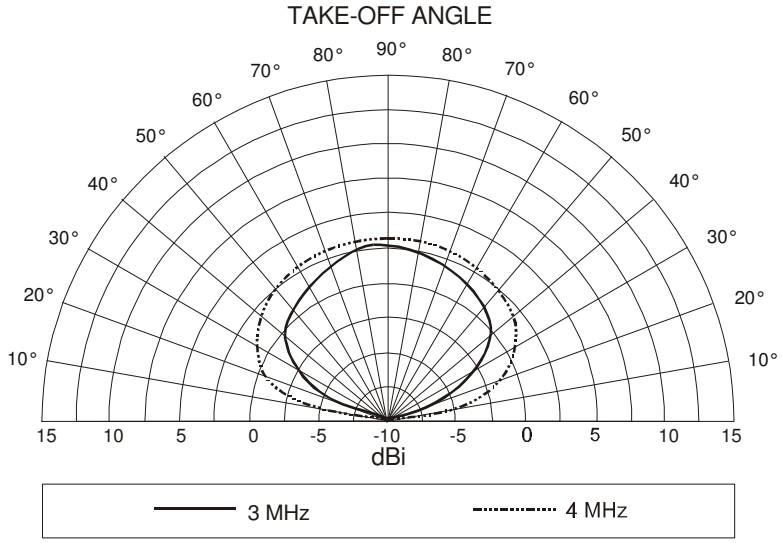

Figure 4-19. 40-Foot Inverted L (Vertical Pattern), 150 Feet Long.

Orient the antenna like a dipole (i.e., the broad side of the antenna should be toward the distant station). These lengths should not be used outside the frequency ranges specified because the antenna radiation pattern changes, and for frequencies much removed from the range, the antenna will become directional off the wire end. (See the sloping wire paragraphs on page 4-34 for using this directional characteristic.) The inverted L antenna can be used as a substitute for the dipole; however, it has less gain than a dipole, and its radiation pattern varies with frequency (unlike a dipole). Figures 4-19,

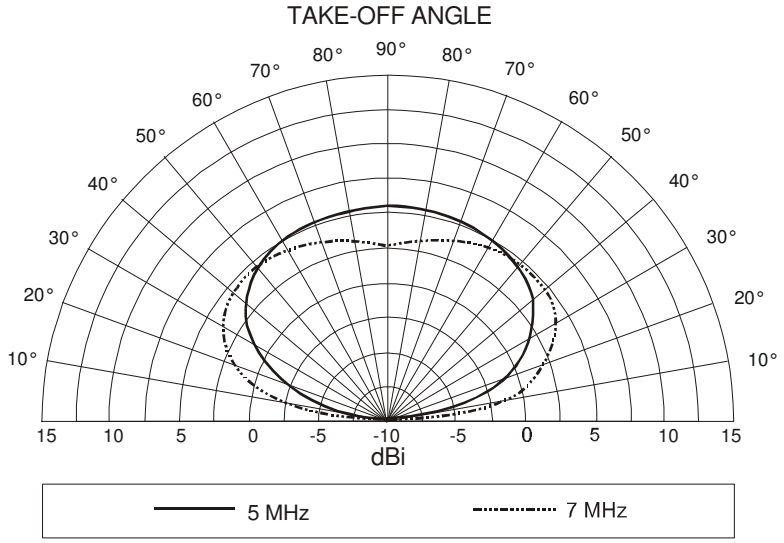

Figure 4-20. 40-Foot Inverted L Antenna (Vertical Pattern), 80 Feet Long.

4-20, and 4-21 on page 4-28 illustrate vertical patterns of various inverted L antennas. Characteristics are—

Frequency range:	**Less than 2:1 over design frequency**
Polarization:	**Vertical from vertical section** **Horizontal from horizontal section**
Power capability:	**1,000 watts**
Radiation pattern	
Azimuthal (bearing):	**Omnidirectional**
Vertical (take-off angle):	**See figures 4-19, 4-20, and 4-21 on page 4-28**

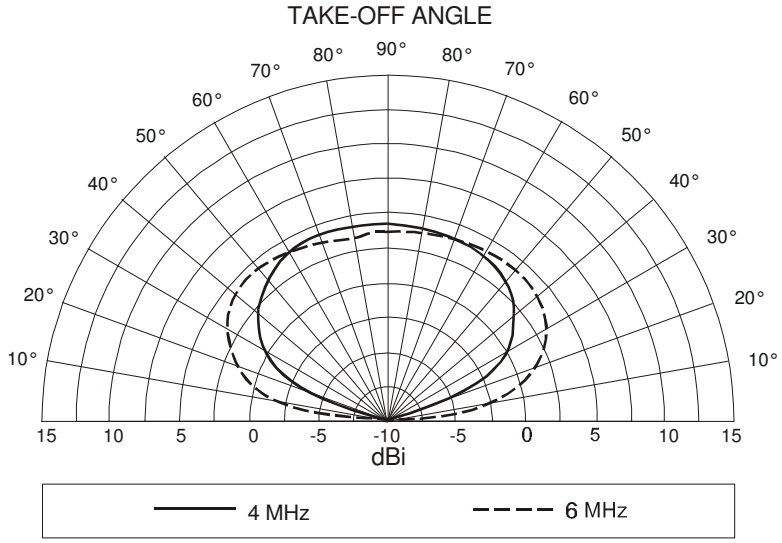

Figure 4-21. 40-Foot Inverted L (Vertical Pattern), 100 Feet Long.

Sloping Vee

The sloping vee is a medium- to long-range sky wave antenna that is simple to construct in the field. Antenna gain and directivity depend on the leg length. For reasonable performance, the antenna

should be at least one wavelength long, but preferably several wavelengths long (see fig. 4-22).

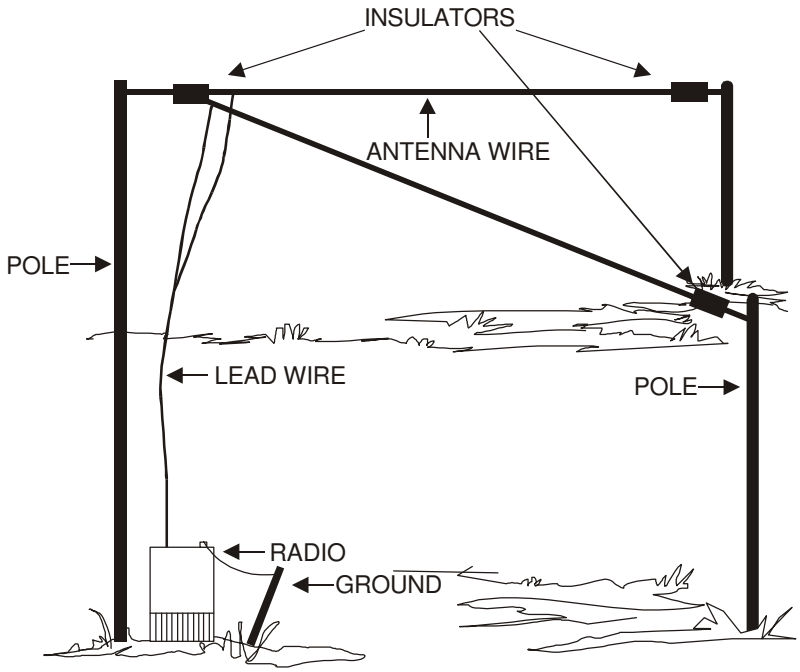

Figure 4-22. Sloping Vee Antenna.

A compromise tactical sloping vee can be constructed using 500-foot legs and a 40-foot support mast. The angle between the two legs is adjusted to provide maximum radiation at the desired take-off angle. Table 4-6 shows the angles between legs (apex angle) that will give poor results for the distances indicated.

Table 4-6. Angle Between Antenna Legs for Poor Results.

Path Length (Miles)	700 to 1000	1000 to 1500	over 1500
Apex Angle (Degrees)	60	45	30

To make the antenna directional, use terminating resistors on each leg on the open part of the vee. The terminating resistors should be 300 ohms and be capable of handling one-half of the transmitter's power output. These terminations are either procured or fabricated locally using supply system parts (100-watt, 106-ohm resistor). Using the terminating resistors, the antenna is aimed so that the line cutting the vee in half is pointed at the distant station.

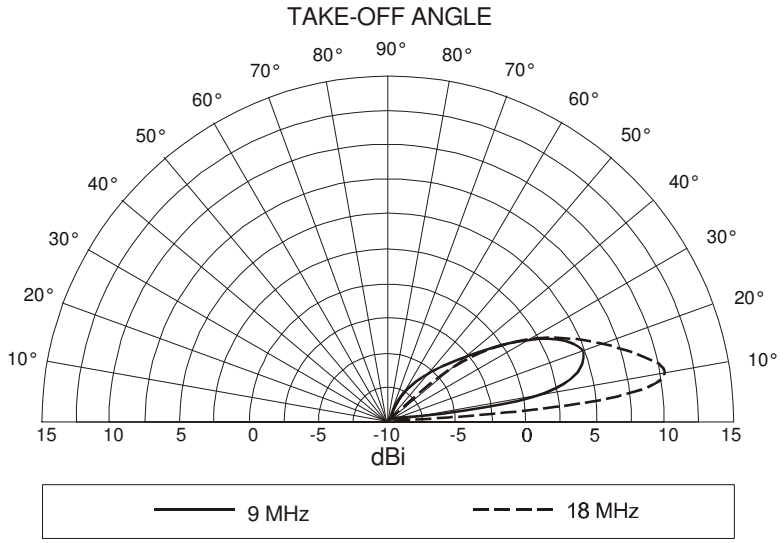

Figure 4-23. 40-Foot Sloping Vee (Vertical Pattern), 500 Feet Long, 30° Apex Angle.

The sloping vee is normally fed with a 600-ohm, open-wire feed line. One side of the feed line is connected to one leg with the other side connected to the other leg. The open-wire feed line can be connected to a 12 to 1 balun, which is then connected to standard coaxial cable. Figures 4-23, 4-24 on page 4-32, and 4-25 on page 4-33 illustrate the vertical patterns for various sloping vee antennas.

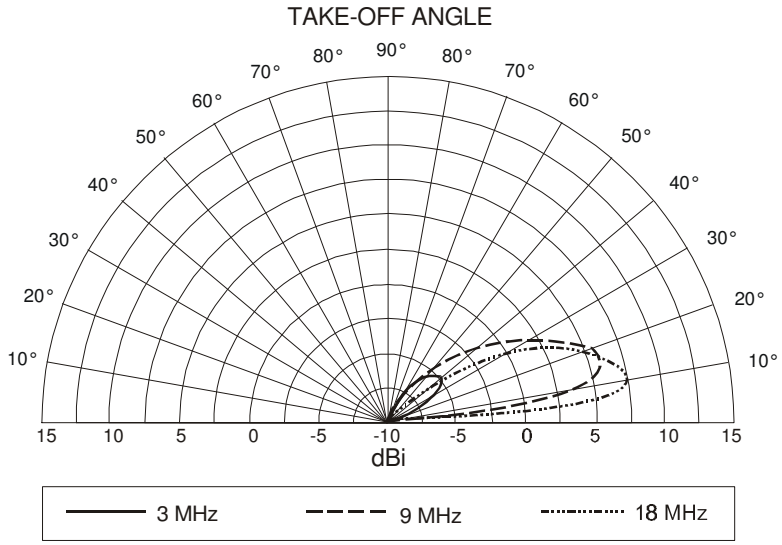

Figure 4-24. 40-Foot Sloping Vee Antenna (Vertical Pattern), 500 Feet Long, 45° Apex Angle.

Characteristics are—

Frequency range:	**3 to 30 MHz**
Polarization:	**Horizontal**
Power capability:	**Depends on terminating resistors**
Radiation pattern	
Azimuthal (bearing):	**Directional (20° either side of direction of radiation)**
Vertical (takeoff angle):	**See Figures 4-23, 4-24 on page 4-32, and 4-25 on page 4-33**

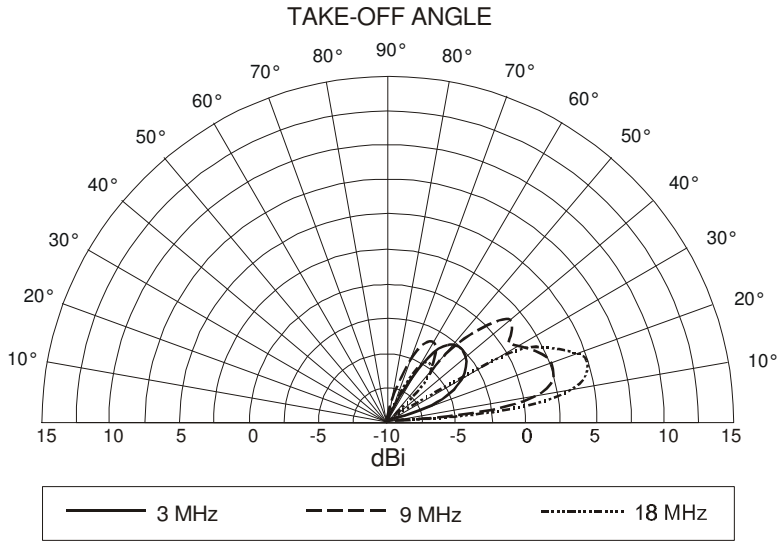

Figure 4-25. 40-Foot Sloping Vee Antenna (Vertical Pattern), 500 Feet Long, 60° Apex Angle.

Sloping Wire

The sloping wire antenna is simple and easy to construct. It requires only one support (see fig. 4-26 on page 4-34). A version of the long wire antenna, the sloping wire produces best results when it is long compared to a wavelength. Tactical sloping wires vary in length from 45 to over 500 feet. The shorter lengths perform rather poorly and should be used only when no other antenna can be erected. The

longer lengths (e.g., 250 feet, 500 feet) can produce good radiation for medium to long sky wave paths.

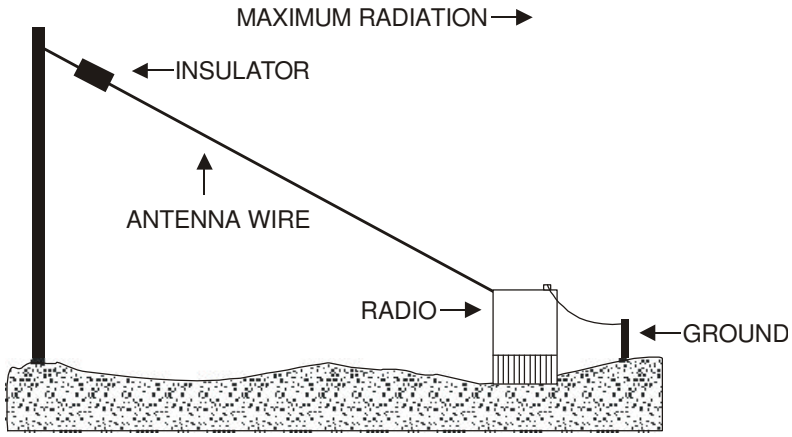

Figure 4-26. Sloping Wire.

A sloping wire can be either terminated or unterminated. If available, use 600-ohm termination because this makes the antenna impedance fairly constant, and a balun can be used to match the antenna to a transmitter. If the antenna is unterminated, use a coupler to match the transmitter to the antenna.

The low end of the wire should be oriened toward the receiving station. If the wire is unterminated, feed the antenna at the low end. If a terminating resistor is used, feed the antenna low end. Figure 4-27 and figures 4-28 and 4-29 on page 4-36 illustrate the vertical patterns for various sloping wire antennas.

Characteristics are—

Frequency range:	**Depends on wire length/configuration**
Polarization:	**Vertical**
Power capability:	**Determined by terminating resistor**
Radiation pattern	
Azimuthal (bearing):	**Bidirectional for unterminated** **Directional for terminated**
Vertical (take-off angle):	**See figure 4-27 and figures 4-28 and 4-29 on page 4-36**

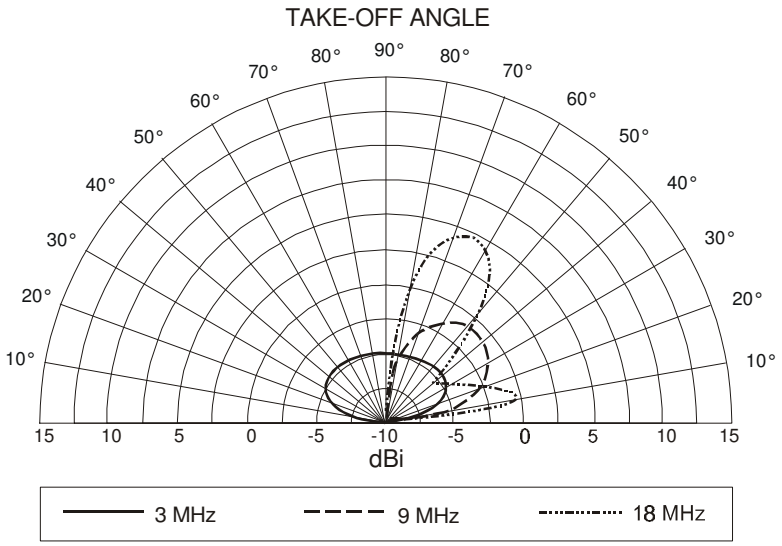

Figure 4-27. 100-Foot Sloping Wire (Vertical Pattern).

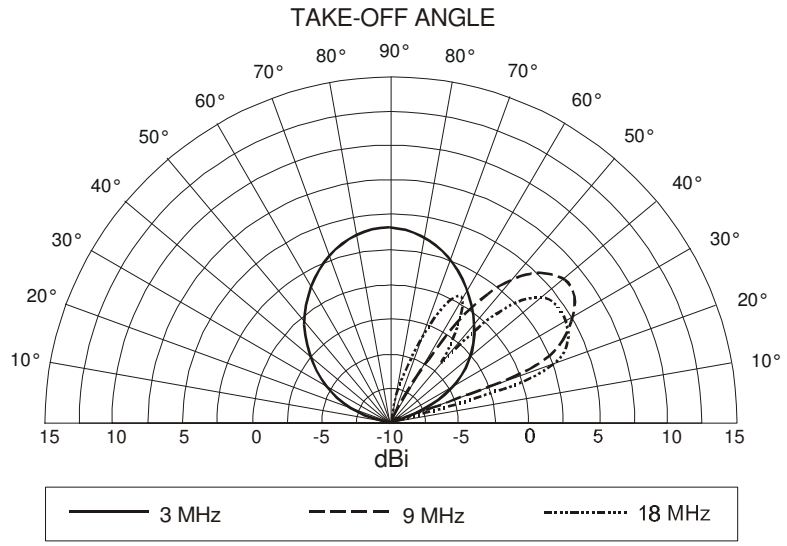

Figure 4-28. 250-Foot Sloping Wire (Vertical Pattern).

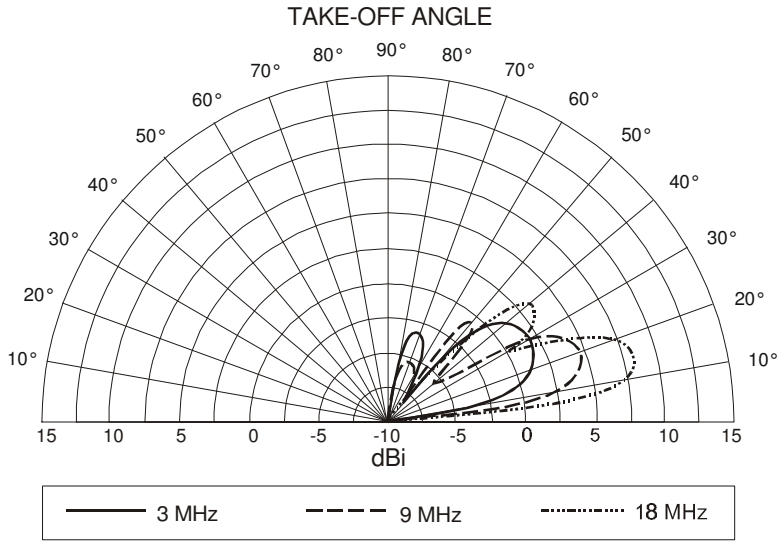

Figure 4-29. 234-Foot Sloping Wire (Vertical Pattern).

Vertical Half-Rhombic

The vertical half-rhombic antenna is a version of the long wire antenna that uses a single center support (see fig. 4-30). Easily constructed, this antenna has a narrow width (as wide as the center support guys), which allows several to be installed in a relatively narrow area. The vertical half-rhombic antenna radiates a medium- to low-angle signal, making it a good choice for medium- to long-range sky wave circuits. Normally, the 500-foot version is the maximum length of antenna that most tactical situations will allow; however, the vertical radiation pattern for a 1,000-foot version is included, so that if the opportunity exists, the antenna can be used for excellent results.

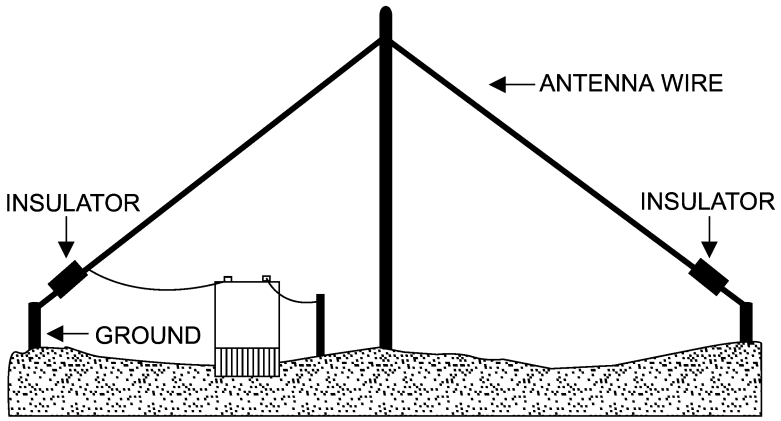

Figure 4-30. Vertical Half-Rhombic Antenna.

The vertical half-rhombic uses a single wire feed either through a coupler or a balun (12 to 1). One of the two terminals of the coupler or balun is attached to the antenna, while the other terminal is grounded. Like other terminated antennas, the terminating resistor (600 ohms) should be able to handle one-half of the transmitter's power output. Terminators can be procured or fabricated locally (100-watt, 106-ohm resistor).

The orientation of this antenna depends on the frequency bands being worked. Below 12 MHz, point the terminated end of the antenna at the distant station; above 12 MHz, aim the antenna 10 feet to either side of the distant station. Figures 4-31 and 4-32 illustrate the vertical patterns for various vertical half-rhombic antennas. Characteristics are—

Frequency range:	**2 to 30 MHz**
Polarization:	**Vertical**
Power capability:	**Determined by terminating resistor**
Radiation pattern

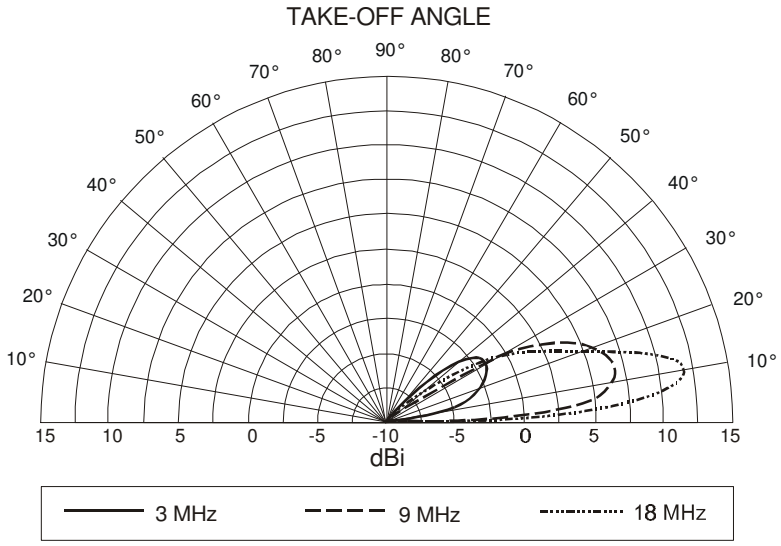

Figure 4-32. 50-Foot Vertical Half-Rhombic (Vertical Pattern), 1,000 Feet Long.

HF NVIS COMMUNICATIONS

NVIS propagation is simply sky wave propagation that uses antennas with high-angle radiation and low operating frequencies. Just as the proper selection of antennas can increase the reliability of a long- range circuit, short-range communications also require proper antenna selection. NVIS propagation is one more weapon in the communicator's arsenal.

To communicate over the horizon to an amphibious ship on the move, or to a station 100 to 300 kilometers away, the operators should use NVIS propagation. The ship's low take-off angle antenna is designed for medium and long-range communications. When the ship's antenna is used, a skip zone is formed. This skip zone is the area between the maximum ground wave distance and the shortest sky wave distance where no communications are possible. Depending on operating frequencies, antennas, and propagation conditions, this skip zone can start at roughly 20 to 30 kilometers and extend out to several hundred kilometers, preventing communications with the desired station.

NVIS propagation uses high take-off angle (60° to 90°) antennas to radiate the signal almost straight up. The signal is then reflected from the ionosphere and returns to Earth in a circular pattern all around the transmitter. Because of the near-vertical radiation angle, there is no skip zone. Communications are continuous out to several hundred kilometers from the transmitter. The nearly vertical angle of radiation also means that lower frequencies must be used. Generally, NVIS propagation uses frequencies up to 8 MHz.

The steep up and down propagation of the signal gives the operator the ability to communicate over nearby ridge lines, mountains, and dense vegetation. A valley location may give the operator terrain shielding from hostile intercept and also protect the circuit from

ground wave and long-range sky wave interference. Antennas used for NVIS propagation need good high take-off angle radiation with very little ground wave radiation (see fig. 4-33).

Using the HF antenna selection matrix (table 4-4 on page 4-8), the AS-2259/GR and half-wave dipole are the only antennas listed that meet the requirements of NVIS propagation. While the inverted vee and inverted L antennas have high-angle radiation, they also can have strong ground wave radiation that could interfere with the close-in NVIS communications. These antennas could be used if terrain shielding prevented the ground wave signal from propagating to the distant station.

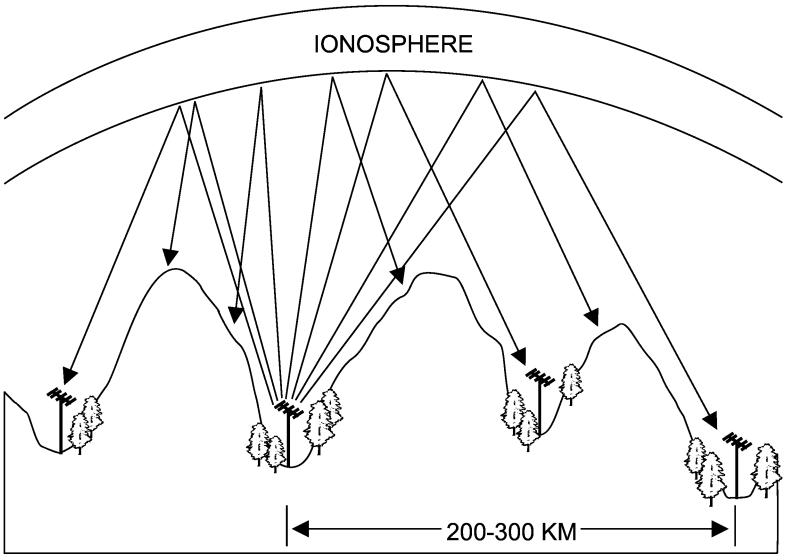

Figure 4-33. NVIS Propagation.

The dipole antenna pattern is illustrated in figures 4-11 and 4-12 on page 4-17 and figure 4-13 on page 4-19. The patterns for 3 and 9 MHz show that large amounts of energy are directed up in the 60° to 90° range. Also, the pattern is the same on both sides of the 90° line. This means that a low dipole would be a good antenna for NVIS propagation. The pattern at 18 MHz is not important because NVIS propagation normally does not use frequencies much above 8 MHz. Set up dipoles on whatever supports are available. Ensure that the height is below a quarter-wavelength, which at 8 MHz is about 30 feet.

Mobile CPs do not always have time to set up a dipole antenna or an AS-2259/GR. Several options are possible. If a Marine is in an MRC-138 vehicle, then use a tilt whip adapter and the 16-foot whip antenna to try to obtain high-angle radiation (fig. 4-34). Tilt the antenna at least 30°. Another option is disconnecting the whip antenna and connecting a 32-foot wire to the antenna base. Run the wire parallel to the ground, and stake it at the distant end the same height above the ground as the radio end. Insulate the staked end from the ground to prevent radio damage (fig 4-35).

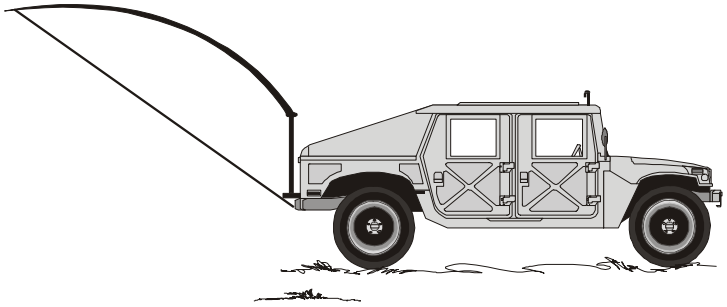

Figure 4-34. AN/MRC-138 with NVIS Antenna.

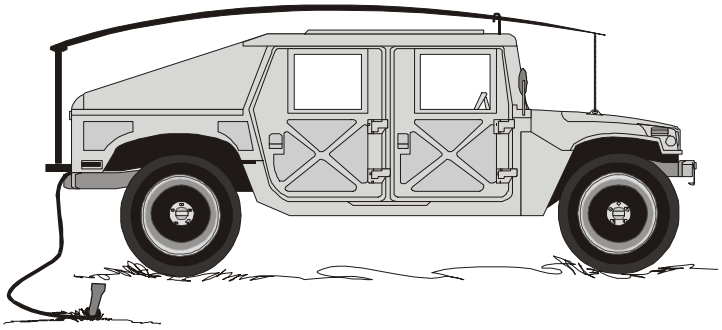

Figure 4-35. AN/MRC-138 with Stationary NVIS Antenna.

WARNING

THE WIRE MUST BE PROTECTED SO THAT MARINES DO NOT WALK INTO IT. IT CARRIES ENOUGH RF ENERGY DURING TRANSMISSION TO CAUSE SEVERE INJURIES.

When using a manpack radio like the AN\PRC-104, the whole radio can be rotated so that the 8-foot antenna is tilted at least 30°. Because of the antenna's flexibility, it will need support on the far end. This support must be a good insulator. Ensure that Marines keep clear of the antenna. Characteristics are—

Frequency range:	**2 to 30 MHz**
Polarization:	**Vertical or horizontal**
Power capability:	**100 to 400 Watts**
Radiation pattern	
Azimuthal (bearing):	**Basically omnidirectional**
Vertical (take-off angle):	**Minimizes skip zone using 90°, 40°, and 20° take-off angle**

(reverse blank)

Chapter 5

VHF and UHF Antenna Selection

FREQUENCIES

The VHF portion of the radio spectrum extends from 30 to 300 MHz. The UHF range reaches from 300 to 3,000 MHz (3 GHz). Both frequency ranges are extremely useful for short-range (less than 50 km) communications. This includes point-to-point, mobile, air-to-ground, and general purpose communications. A wavelength at these frequency ranges is considerably shorter than those in the HF range, and simple antennas are much smaller.

Because the VHF and UHF antennas are small, it is possible to use multiple radiating elements to form arrays, which provide a considerable gain in a given direction or directions. An array is an arrangement of antenna elements, usually dipoles, used to control the direction in which most of the antenna's power is radiated.

Generally, many more types of antennas are available and useful in the VHF and UHF range than at HF. Several of these types will be discussed in this chapter since they are useful for various field applications.

Within the VHF and UHF portion of the spectrum, there are several subfrequency bands for specific uses. The 118 to 136 MHz range is generally reserved on a worldwide basis for air-to-ground communications and is known as the VHF aircraft band. The 225 to 400 MHz range is also allocated for air-to-ground use and is known as the UHF aircraft band. The 148 to 174 MHz and 450 to 470 MHz

ranges are assigned to many activities, including citizens (public) communications (e.g., mobile, police, weather, taxis, and general purpose).

POLARIZATION

In many countries, FM and TV broadcasting in the VHF range use horizontal polarization. One reason is because it reduces ignition interference, which is mainly vertically polarized. Mobile communications often use vertical polarization for two reasons. First, the vehicle antenna installation has physical limitations, and second, so that reception or transmission will not be interrupted as the vehicle changes its heading to achieve omnidirectionality.

Using directional antennas and horizontal polarization (when possible) will reduce manmade noise interference in urban locations. Horizontal polarization, however, should be chosen only where an antenna height of many wavelengths is possible. Ground reflections tend to cancel horizontally polarized waves at low angles. Use only vertically polarized antennas when the antenna must be located at a height of less than about 10 meters above ground, or where omnidirectional radiation or reception is desired.

GAIN AND DIRECTIVITY

VHF and UHF (above 30 MHz) antenna gain and directivity are extremely important for several reasons. Assuming the same antenna gain and propagation path, the received signal strength drops as frequency is increased. At VHF and UHF, more of the received signal is lost in the transmission line than is lost at HF. A 10 to 20 dB loss is not uncommon in a 30 meter length of coaxial line at 450 MHz.

At frequencies below 30 MHz, system sensitivity is almost always limited by receiver noise rather than by noise external to the antenna (e.g., atmospheric and manmade interference). Generally, wider modulation or signal bandwidths are employed in VHF and UHF transmissions than at HF. Since system noise power is directly proportional to bandwidth, additional antenna gain is necessary to preserve a usable S/N ratio.

VHF and UHF antenna directivity (gain) aids security by restricting the amount of power radiated in unwanted directions. Receiver sensitivity is generally poorer at VHF and UHF (with the exception of high quality state-of-the-art receivers). Obstructions (e.g., buildings, trees, hills) may seriously decrease the signal strength available to the receiving antenna because VHF and UHF signals travel a straight LOS path.

Gain

Obtaining communications reliability over difficult VHF and UHF propagation paths requires considerable attention to the design of high-gain, directive antenna arrays at least at one end of the communications link. Unlike HF communications, the shorter VHF and UHF wavelengths support walkie-talkie transceivers and simple mobile transmission units. Communicating or receiving with such devices over distances beyond 1 or 2 km requires maximum antenna gain at the base station site or fixed end of the link.

Directivity

Because VHF and UHF wavelengths are so short, reliable prediction of diffraction, refraction, and reflection effects are not practical. One must depend entirely on LOS paths. For best results, attempt to establish VHF and UHF communications paths that are as free of obstacles as possible. The VHF and UHF wavelengths are

short enough that it is possible to construct resonant antenna arrays. An array provides directivity (the ability to concentrate radiated energy into a beam that can be aimed at the intended receiver). Arrays of resonant elements, (e.g., half-wave dipoles), can be constructed of rigid metal rods or tubing or of aluminum or copper foil laid out or pasted on a flat nonconducting surface. Directing power helps to increase the range of the communications path and tends to decrease the likelihood of interception or jamming from hostile radio stations. However, such highly directive antennas place an added burden on the operator to ensure that the antenna is pointed properly.

TRANSMISSION LINES

Choosing transmission lines at VHF and UHF depends on many factors. Generally, twin-lead has much lower loss than small diameter coaxial cable. Twin-lead is preferred over coaxial when transmission line lengths exceed 10 meters. Twin-lead is much more susceptible to picking up objectionable manmade noise than is well shielded coaxial cable. Also, most modern VHF and UHF equipment employs unbalanced input and output circuitry with a 50-ohm impedance. Such equipment requires either using coaxial cable or a balun to feed a twin-lead or two-wire balanced transmission line. Noise pickup by twin-lead transmission lines may be considerably reduced by twisting the line along its length.

When using twin-lead, the spacing between the wires of the line should not exceed 0.05 λ. If the spacing is an appreciable part of a wavelength, the line will radiate and receive energy like the antenna. This effect will alter the intended antenna radiation pattern. To further reduce local noise pickup, keeping twin-lead clear of metal objects (e.g., gutters and window frames). Twice the wire spacing in the twin-lead is sufficient clearance.

RADIATORS

A radiator is the antenna component that transmits RF energy.

Vertical Radiator

A vertical radiator for general coverage use at UHF should be one-quarter wavelength long. Longer vertical antennas do not have their maximum radiation at right angles to the line of the radiator. They are not practical for use where the greatest possible radiation parallel to the Earth is desired. It is important that the antenna be decoupled from the coaxial transmission line. This will prevent unwanted radiation currents from flowing along the outside of the cable, which will distort the antenna pattern. Use a sleeve, ground plane, or counterpoise to perform decoupling.

Cross Section Radiator

Aluminum tubing is commonly used for dipoles and radiation elements. They are so short that the expense of larger diameter conductors is relatively low. With such conductors, the antenna will tune much more broadly. This is very desirable, particularly when an antenna or array is used over an entire frequency band.

Large cross section radiators have a shorter resonant length than a radiator or mode of small diameter wire. A tubing radiator mode is seldom longer than 90 percent of a half-wavelength for a dipole at frequencies above 100 MHz.

INSULATION

Insulation or dielectric material quality is more important at VHF and UHF than at frequencies below 30 MHz. Many insulators that perform well in the HF range are poor or unusable for fabricating

antennas operating at frequencies above 100 MHz. Ordinary wood is a good example. In minimal rainfall climates, using very dry redwood, maple, or fir boiled in paraffin wax for several hours is fairly successful up to frequencies as high as 560 MHz. The neck of a glass soft drink bottle or other similar items work reasonably well up to frequencies as high as 1 GHz. Several modern plastics, used throughout the world, also make excellent insulators (e.g., fiberglass, polystyrine, polyethylene, and Styrofoam). Pieces of these plastics in usable shapes can be found almost everywhere, and, with a little ingenuity, can be used as insulation in the design of many VHF and UHF antennas. Avoiding insulation entirely is possible by choosing an antenna design with elements supported at lower voltage (high current) points (e.g., the Yagi antenna).

INTERFERENCE

Obtaining optimum coupling between the antenna and transmission line and between the transmission line and the receiver or transmitter circuits is a major concern.

Noise

While atmospheric and manmade noise usually limit the ultimate sensitivity of an HF receiving system, a VHF or UHF receiving system is almost always limited by receiver noise. External (atmospheric) noise is virtually nonexistent at frequencies higher than 100 MHz. Automobile ignition and other forms of manmade static affect frequencies well into the UHF band.

Multipath Interference

VHF and UHF radio waves are highly attenuated when they travel through most materials. Select a location which is as free as possible of obstacles in the direction of desired propagation. It is possible

to use relay stations or carefully placed reflectors when obstacles interfere with the direct path.

When operating from areas where the transmission path is bounded rather closely by reflective objects (e.g., buildings or metal towers) the possibility of multipath exists. Whenever conditions are such that radio signals travel two or more separate paths from the transmitting to the receiving antenna, a phenomenon known as an interference pattern is created around the receiving antenna. There will be zones where the incoming signal is received very strongly (constructive interference) with areas of weak signal between (destructive interference). If each of the two signal has the same strength, complete cancellation will occur in the destructive interference zones, and no signal will be received. At VHF and UHF the created interference patterns are small enough to permit moving out of a destructive zone and into a constructive zone within the space of only a meter or so.

It is difficult to predict the location of an interference pattern. Optimizing antenna location is a must for good results. Sometimes a secondary path is created as the result of reflection from a moving object (e.g., an automobile or airplane). The resulting interference pattern will not be stationary, but will move past the antenna so that the received signal appears to flutter between good and poor reception. Multipath problems can be particularly severe when either the transmitting or receiving antenna is moving. Diversity techniques such as two separated antennas or circular polarization should help to alleviate the effects of multipath interference. High gain (highly directive) antennas, both on the transmitter and the receiver, can reduce signal loss from multipath interference.

Vegetated Areas

VHF and UHF communications through a dense forest over distances of more than a few kilometers can often be very difficult. In many tropical regions, trees and underbrush absorb VHF and UHF radio energy. In addition to the ordinary free space loss between transmitting and receiving antennas, a radio wave passing through a forest undergoes an additional loss that is measured in dBs per km. This extra loss increases rapidly as the transmission frequency increases.

Near the ground (i.e., antenna heights of less than 3 meters) vertical polarization is preferred. However, if it is possible to elevate both receiving and transmitting antennas as much as 10 to 20 meters, horizontal polarization is preferable to vertical polarization. Considerable reduction in total path loss results if either or both the transmitting and receiving antennas can be placed above the tree level through which communications must be made.

Increasing antenna gain may provide an improved signal strength that exceeds the added antenna gain by reducing the number of multipath reflections from trees along the propagation path. The higher gain antenna exhibits a much narrower radiation pattern which includes fewer trees in its beam. Generally, this effect is most noticeable with antenna gains higher than 15 dB or azimuthal half-power beam of less than 35°.

Communications through heavily forested areas over distances greater than 10 kms may require a transmitter power of at least 10 watts and antenna gains of 10 dB or more, depending on antenna height, terrain features, type of trees, moisture content, and numerous other factors. If communication is required over distances

exceeding 30 kms, it may be necessary to use high-angle ionospheric propagation in the 3 to 10 MHz frequency range (i.e., HF) to obtain a reliable circuit.

ANTENNA TYPES

The vertical whip is the most commonly used antenna. The OE-254 is a broadband, omnidirectional, biconical antenna. Antennas located in places which are enclosed mostly in a metal shell or container (e.g., an automobile) cannot be expected to perform as well as if located outside the enclosure. Most of the antenna types usable in the HF range are also usable in the VHF and UHF bands. In the VHF and UHF ranges, use the same antenna for transmitting and receiving.

Vertical Whip

It is easy to use and part of every radio set. In mobile situations, it is the only antenna that can be used. In stationary operations, the vertical whip is not a good choice. It cannot be elevated for good omnidirectional VHF LOS communications, and it radiates in useless directions if communications are point-to-point.

If the tactical situation prevents using an antenna other than the vertical whip, steps can be taken to improve its performance. Ensure that the antenna is vertical. This can be a problem when using the manpack short whip or tape in the prone position. Use the flexible base on the tape to ensure that the antenna is in a vertical position.

Place a reflector behind the whip to direct radiation in a general direction. A reflector is a vertical wire or another whip placed one-quarter wavelength behind the radiating whip. Place the reflector at the same height as the whip, and insulate it from the ground. The

reflector reflects some of the radio energy back towards the whip and provides a broad beam of energy towards the distant station. Characteristics are—

Frequency range:	30 to 88 MHz
Polarization:	Vertical
Power capability:	Matched to specific radio
Radiation pattern	
Azimuthal (bearing):	
Vertical (take-off angle):	

OE-254

The OE-254 (fig. 5-1) is scheduled to replace the RC-292. Unlike the RC-292, the OE-254 does not require tuning for specific bands and can cover the 30 to 87.975 MHz VHF band without adjustments. Three upward and three downward radial elements simulate two cones which provide omnidirectional VHF LOS radiation. The antenna is usually mounted on a 33-foot 8-inch mast for an overall height of 41 feet 9 inches. The antenna may be installed at lower heights; however, care should be taken to ensure that the lower and upper mast adapter assemblies are always used. An 80-foot coaxial cable comes with the antenna for direct connection to a radio.

Frequency range:	30 to 88 MHz
Polarization:	Vertical
Power capability:	350 watts
Radiation pattern	
Azimuthal (bearing):	Omnidirectional
Vertical (take-off angle):	

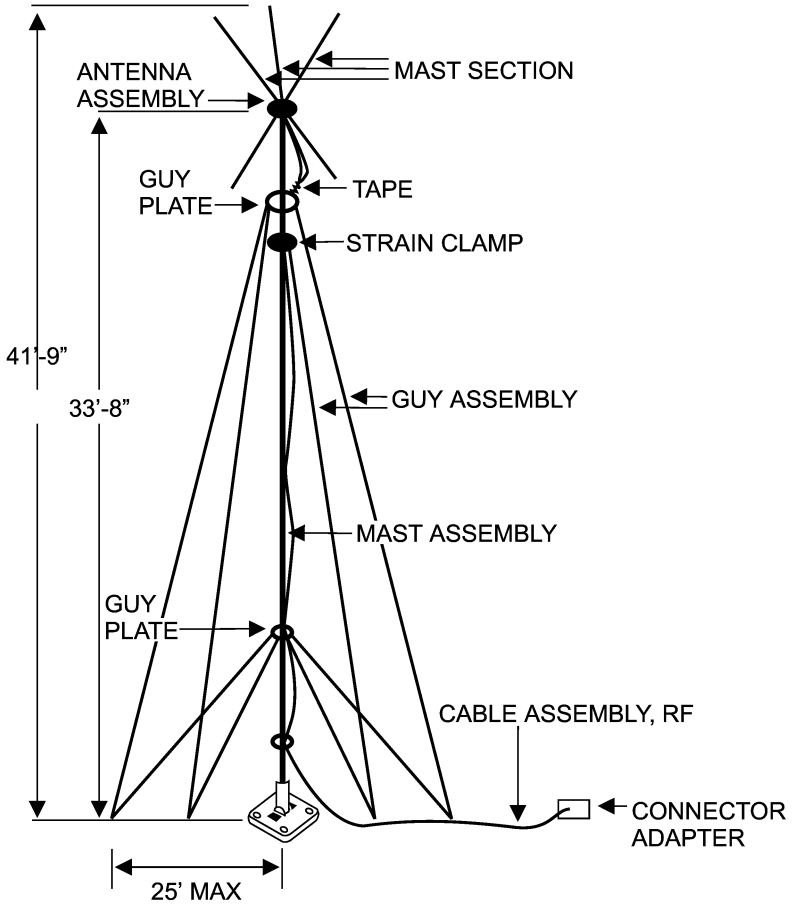

Figure 5-1. Installed OE-254 Antenna.

Antenna Within Vehicle Interior

Antennas located inside vehicles will lose some radiation through the window openings. It is difficult to predict how much radiation will escape or how much the original antenna radiation pattern will be affected by the enclosure. The pattern modification depends on the vehicle size and its openings and on the location of the antenna inside. Select antennas which operate above the cutoff frequency of the window openings. An opening in a metal container which is less than 0.5 λ in the dimension perpendicular to the plane of polarization will be severely attenuated or cutoff as it traverses the opening. Lower frequency waves will suffer even greater attenuation.

HF Antenna Types Usable at VHF and UHF

Simple vertical half-wave dipole and quarter-wave monopole antennas are very popular for omnidirectional transmission and reception over short-range distances. For longer distances, rhombic antennas made of wire and somewhat similar in design to HF versions may be used to good advantage at frequencies as high as 1 GHz. Another HF antenna, the Yagi, is equally popular in the VHF and UHF ranges. However, while Yagis with more than three or four elements are seldom used at HF, Yagi designs with as many as 15 elements, or more, are quite common at VHF and UHF.

Dual-Function Antennas

Because there is no sure method of accurately pointing a transmitting antenna, accomplish this task by first using the antenna in reception and orienting it for the best received signal. Positioning the antenna in this manner assures that, according to the reciprocity theorem, the antenna is optimally oriented for transmitting. If two-way communications are desired (i.e., transmitting and receiving alternately) a switch to toggle quickly back and forth between transmitter and receiver is required. Design the switch so that it will not

upset the impedance on the transmission line, causing unwanted received or transmitted power loss. When using coaxial cable as transmission line, use suitable, commercially available, low-loss coaxial antenna switching relays if possible.

In the 225 to 400 MHz and 450 to 470 MHz frequency ranges, most antennas are quite small. Mount two identical antennas, using one for transmitting and one for receiving. Separate transmission lines may then be used, eliminating the need for an antenna relay.

(reverse blank)

Chapter 6

Field Repair and Expedients

Antennas sometimes break or sustain damage, causing poor communications or communications failure. If a spare is available, use it to replace the damaged antenna. When there is no spare, construct an expedient antenna. The following paragraphs discuss antenna and support repair and constructing and adjusting expedient antennas.

REPAIR TECHNIQUES

Whip Antennas

A broken antenna (whip) can be repaired temporarily. If the whip is broken into two sections, rejoin the sections. Remove the paint and clean the sections where they will rejoin to ensure a good electrical connection. Place the sections together, secure them with a pole or branch, and lash them with bare wire or tape above and below the break (see fig. 6-1 (A) on page 6-2).

If the whip is badly damaged, use a length of field wire (WD1/TT) the same length as the original antenna. Remove the insulation from the lower end of the field wire antenna, twist the conductors together, stick them in the antenna base connector, and secure with a wooden block. Use either a pole or a tree to support the antenna wire (see fig. 6-1 (B) on page 6-2).

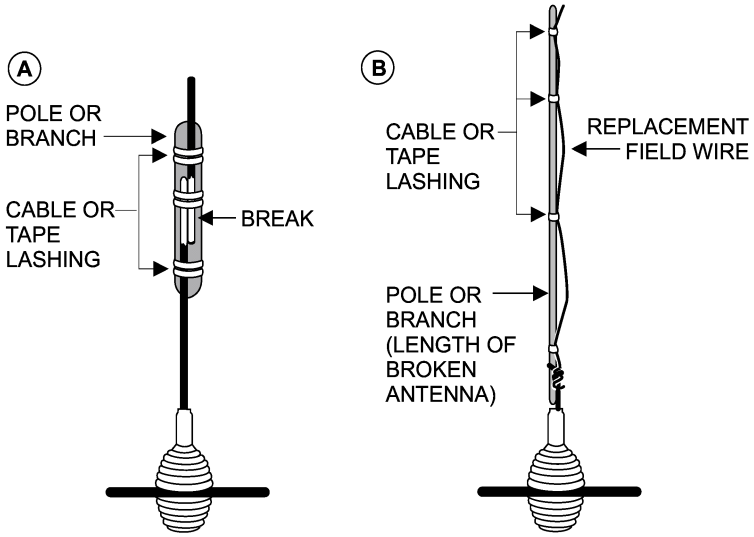

Figure 6-1. Emergency Repair of Broken Whip.

Wire Antennas

Expedient wire antenna repair may involve repairing or replacing the antenna or transmission line wire or repairing or replacing the assembly that supports the antenna. When one or more antenna wires are broken, repair the antenna by reconnecting the broken wires. Lower the antenna to the ground, clean the ends of the wires, and twist the wires together. Solder the connection if possible. If the antenna is damaged beyond repair, construct a new one. Make sure that the substitute wire is the same length as the original.

Antenna supports may also require repair or replacement. Use a substitute item in place of a damaged support. If properly insulated, any material of adequate strength can be used. If the radiating element is not properly insulated, field antennas may be shorted to ground and rendered ineffective. Many commonly found items can

be used as field expedient insulators (fig. 6-2). The best are plastic or glass, including plastic spoons, buttons, bottle necks, and plastic bags. Less effective than plastic or glass, but better than no insulators at all, are wood and rope, or both, in that order. The radiating element—the actual antenna wire—should touch only the antenna terminal and be physically separated from all other objects, other than the supporting insulator.

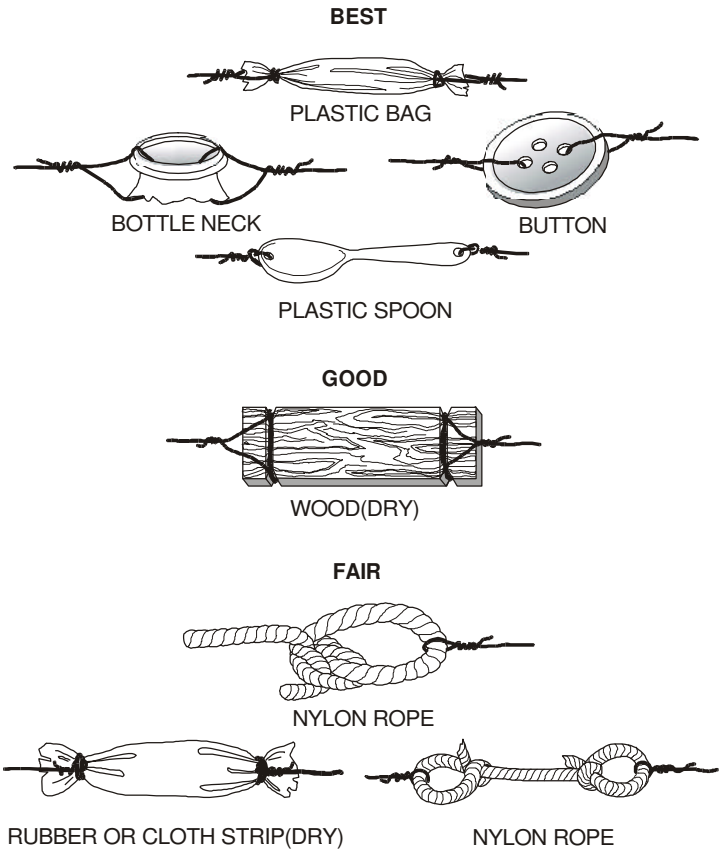

Figure 6-2. Improvised Insulators.

Guys

Lines used to stabilize antenna supports are called guys. These lines are usually wire, manila rope, or nylon rope. If a rope breaks, repair it by tying the two broken ends together. If the rope is too short after tying, lengthen it by adding another piece of rope or a piece of dry wood or cloth. If a guy wire breaks, replace it with another piece of wire. Figure 6-3 shows how to repair a guy line with a spoon.

Masts

Some antennas are supported by masts. If a mast breaks, replace it with another mast the same length. If long poles are not available, overlap short poles and lash them with rope or wire to provide a pole of the required length. Figure 6-3 shows how to make an expedient mast repair.

TIPS ON CONSTRUCTION AND ADJUSTMENT

Constructing the Antenna

The best kinds of wire for antennas are copper and aluminum. In an emergency, use any type that is available. The exact length of most antennas is critical. An expedient antenna should be the same length as the antenna it replaces.

Antennas supported by trees can usually survive heavy wind storms if the trunk of a tree or a strong branch is used as a support. To keep the antenna taut and to prevent it from breaking or stretching as the trees sway, attach a spring or old inner tube to one end of the antenna. Another technique is to pass a rope through a pulley or eyehook, attach the rope to the end of the antenna, and load the rope with a heavy weight to keep the antenna tightly drawn.

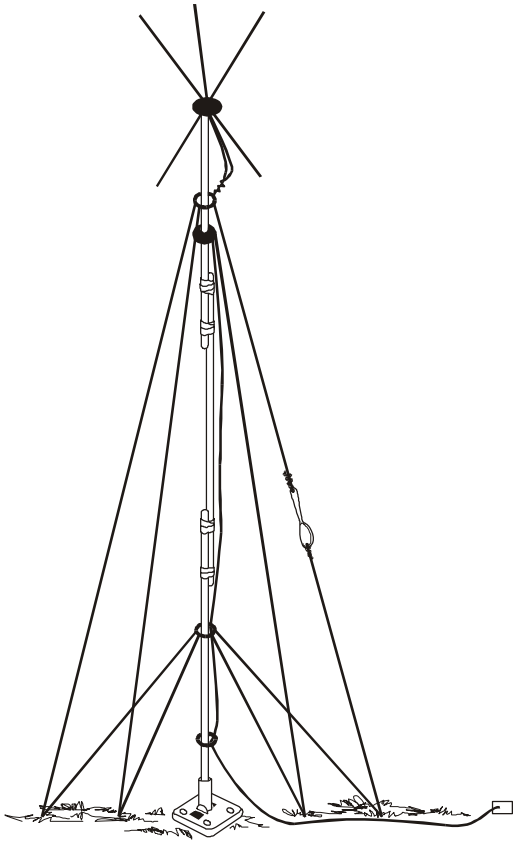

Figure 6-3. Repaired Guy Line and Mast.

Guys used to hold antenna supports are made of rope or wire. To ensure that wire guys will not affect antenna operation, cut the wire into several short lengths and connect the pieces with insulators.

Adjusting the Antenna

An improvised antenna may change a radio set's performance. Use the following methods to determine if the antenna is operating properly.

Use a distant station to test the antenna. If the signal received from this station is strong, the antenna is operating satisfactorily. If the signal is weak, adjust the antenna and transmission line height and length to receive the strongest signal at a given receiver volume control setting. This is the best method of tuning an antenna when transmission is dangerous or forbidden.

Most Marine Corps cadets use the transmitter to adjust the antenna. Set the transmitter controls in position for normal operation. Then, tune the system by adjusting the antenna height and length and the transmission line length to obtain the best transmission output.

WARNING

SERIOUS INJURY OR DEATH CAN RESULT FROM CONTACT WITH THE RADIATING ANTENNA OR MEDIUM- OR HIGH-POWER TRANSMITTER. TURN THE TRANSMITTER OFF WHILE MAKING ADJUSTMENTS TO THE ANTENNA.

Impedance-matching a load to its source is an important consideration in transmissions' systems. If the load and source are mismatched, part of the power is reflected back along the transmission line towards the source. This reflection prevents maximum power transfer, causes erroneous measurements of other parameters, or causes circuit damage in high-power applications.

The power reflected from the load interferes with the incident (forward) power, creating standing waves of voltages and current along the line. The ratio of standing-wave maximal to minimal is directly related to the impedance mismatch of the load. The standing-wave ratio (SWR) provides the means to determine impedance and mismatch.

FIELD EXPEDIENT ANTENNAS

VHF Considerations

SINCGARS VHF radios provide the primary means of communications means for Marine Corps forces around the world. SINCGARS radios operate in both single-channel and frequency hopping modes. It is important for CIS personnel to remember that when using SINCGARS radios in the frequency hopping mode, field expedient VHF antennas should not be used. CIS personnel should only use the whip antenna or the OE-254 antenna when operating in the frequency hopping mode.

HF Considerations

Vertical antennas are omnidirectional. They transmit and receive equally well in all directions. Most manpack portable radios use a vertical whip antenna. Improvise a by using a metal pipe or rod of the correct length, held erect by guys. Insulate the lower end of the antenna from the ground by placing it on a large block of wood or other insulating material. Support a vertical wire antenna with a tree or a wooden pole (fig. 6-4 on page 6-8). For short, vertical antennas, use the pole without guys (if properly supported at the base). If the vertical mast is too short to support the wire upright, modify the connection at the top of the antenna.

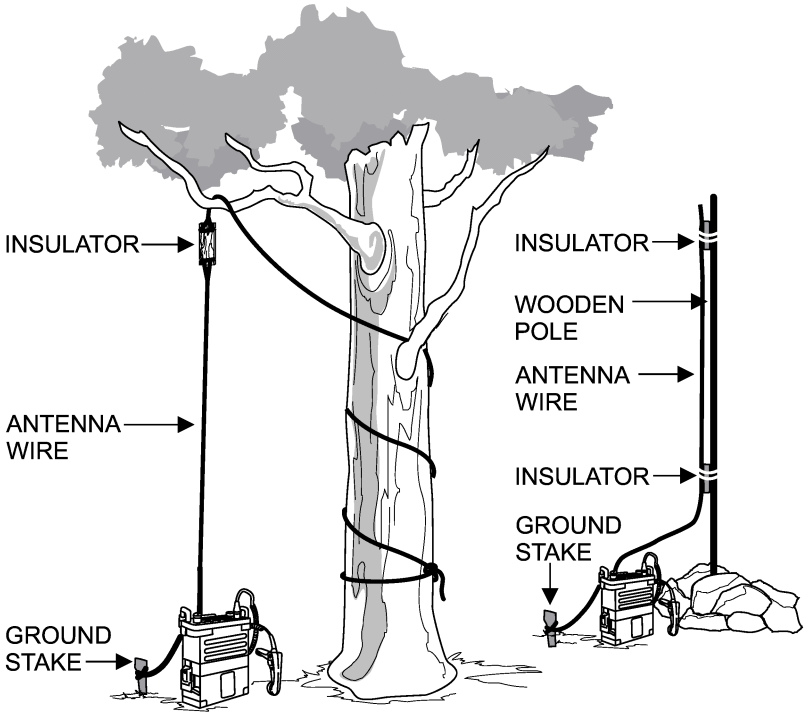

Figure 6-4. Field Substitutes for Support of Vertical Wire Atennas.

End-Fed Half-Wave Antenna

Construct an expedient, end-fed half-wave antenna from available materials (e.g., field wire, rope, and wooden insulators). This antenna's electrical length is measured from the antenna terminal on the radio set to the far end of the antenna (fig. 6-5).

For best performance, construct the antenna longer than necessary, then shorten it, as required, until best results are obtained. Connect the radio set's ground terminal to a good Earth ground for functional efficiency.

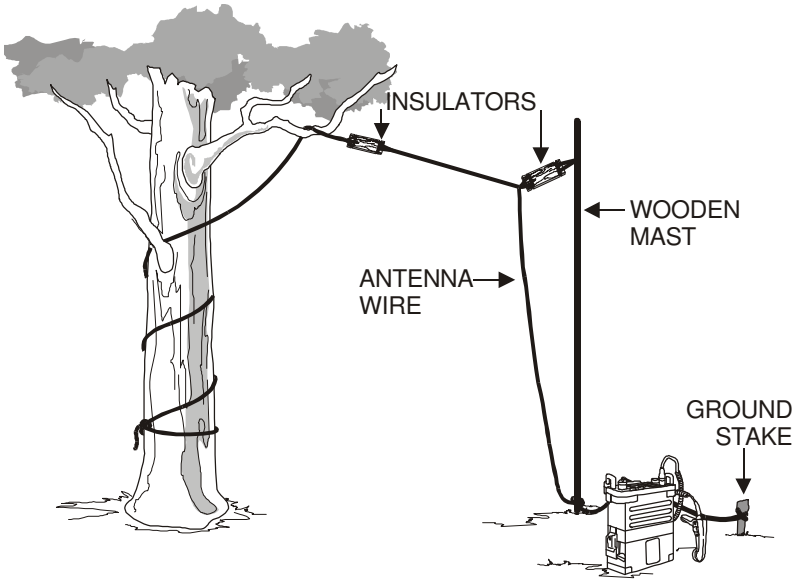

Figure 6-5. End-Fed Half-Wave Antenna.

Center-Fed Doublet Antenna

The center-fed doublet is a half-wave antenna consisting of two quarter-wavelength sections on each side of the center. See figure 6-6 on page 6-10 for constructing an improvised doublet antenna for use with FM radios.

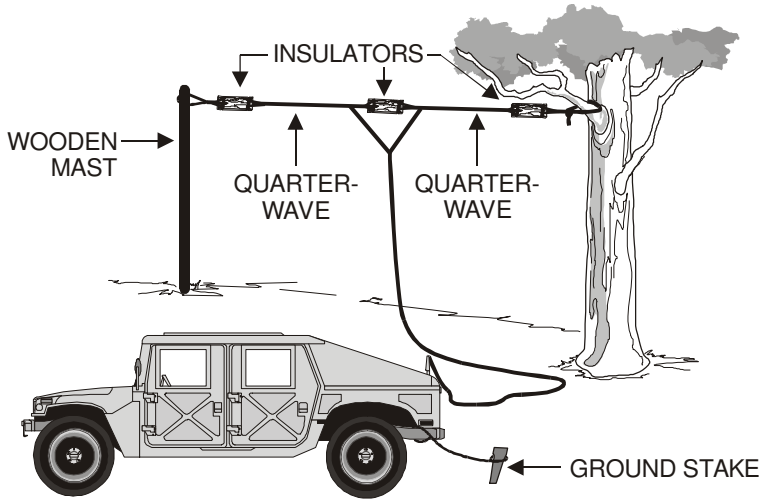

Figure 6-6. Center-Fed Doublet Antenna.

Doublet antennas are directional broadside to their length, which makes the vertical doublet antenna essentially omnidirectional. The radiation pattern is doughnut shaped. The horizontal doublet antenna is bidirectional.

Compute the length of a half-wave antenna by using the formula in chapter 4. Cut the wires as closely as possible to the correct length because the antenna wires' lengths are important.

A transmission line conducts electrical energy from one point to another and transfers the output of a transmitter to an antenna. Although it is possible to connect an antenna directly to a transmitter, the antenna generally is located some distance away. In a vehicular installation, for example, the antenna is mounted outside, and

the transmitter is inside the vehicle. A transmission line, therefore, is necessary as a connecting link.

Center-fed half-wave FM antennas can be supported entirely by pieces of wood. See figure 6-7 (A) for a horizontal antenna of this type. See figure 6-7 (B) for a vertical antenna. These antennas can be rotated to any position to obtain the best performance. If the antenna is erected vertically, the transmission line should be brought out horizontally from the antenna for a distance equal to at least one-half of the antenna's length before it is dropped down to the radio set.

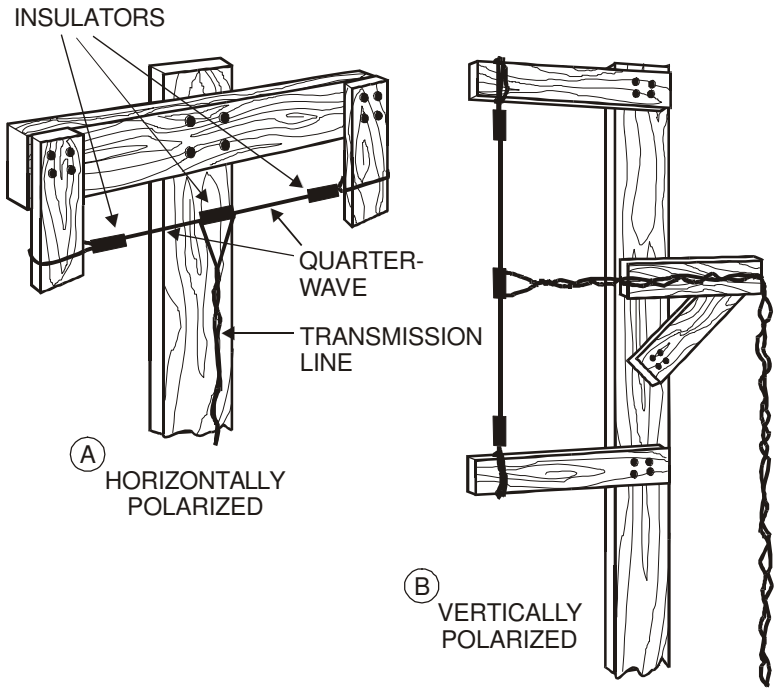

Figure 6-7. Center-Fed Half-Wave Antenna.

A short, center-fed half-wave antenna is shown in figure 6-8. The antenna ends are connected to a piece of dry wood (e.g., a bamboo pole). The bend in the pole holds the antenna wire straight. Another pole, or bundle of poles, serves as the mast.

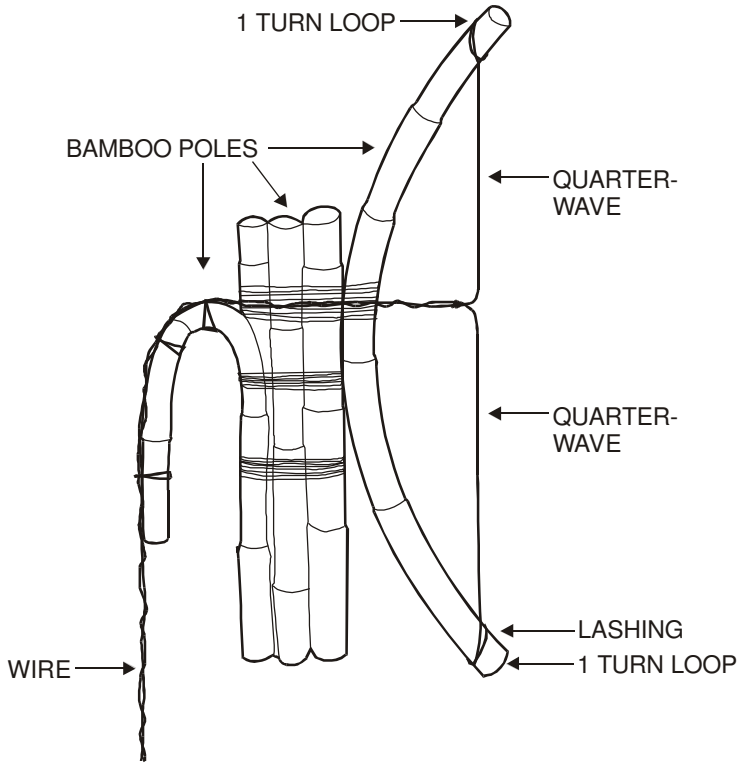

Figure 6-8. Bent Bamboo Antenna.

Figure 6-9 shows an improvised vertical half-wave antenna. This technique is used primarily with FM radios. In heavily wooded areas it is effective for increasing the range of portable radios. The

top guy wire can be connected to a limb or passed over the limb and connected to the tree trunk or a stake.

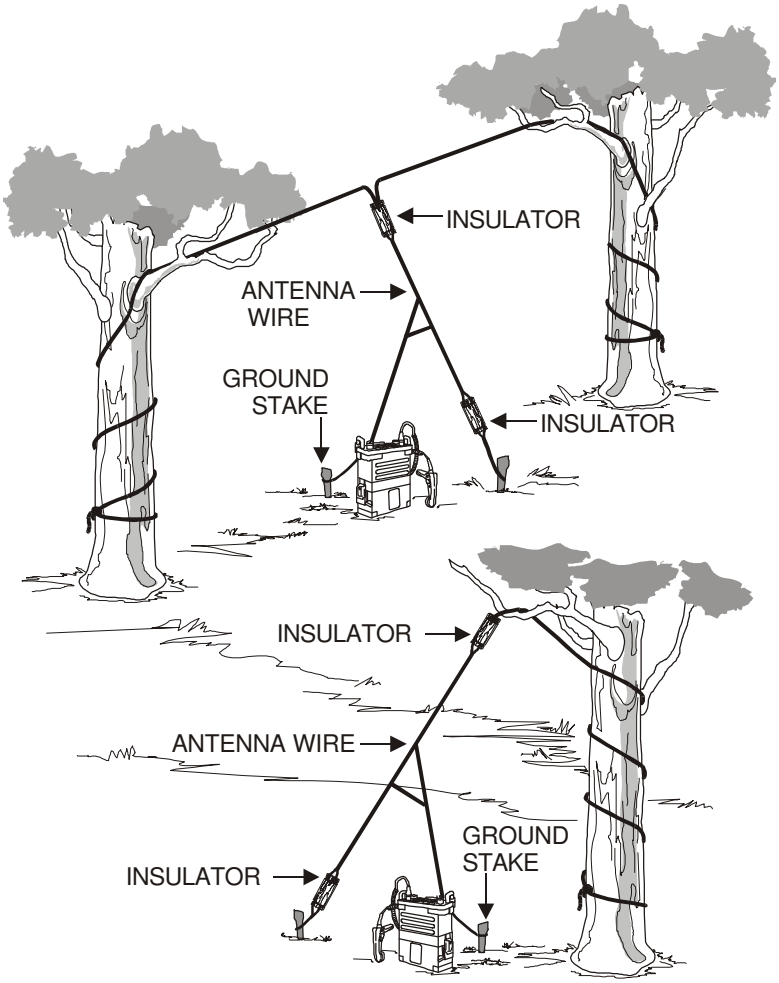

Figure 6-9. Improvised Vertical Half-Wave Antenna.

FIELD EXPEDIENT DIRECTIONAL ANTENNAS

The vertical half-rhombic, the long wire, and the yagi are field expedient directional antennas.

Vertical Half-Rhombic and Long-Wire Antennas

The vertical half-rhombic antenna (fig. 6-10) and the long-wire antenna (fig. 6-11) radiate a directional pattern and primarily transmit or receive HF signals. They consist of a single wire, preferably two or more wavelengths, supported on poles at a height of 3 to 7 meters (10 to 20 feet) above the ground. The antennas also operate satisfactorily as low as 1 meter (approximately 3 feet) above the ground. Connect the far end of the wire to a ground through a noninductive 500- to 600-ohm resistor. To ensure the transmitter's output power does not burn out the resistor, use a resistor that is rated at least one-half the wattage output of the transmitter. Use a reasonably good ground (e.g,. a number of ground rods or a counterpoise) at both antenna ends.

Yagi Antenna

The Yagi antenna (fig. 6-12) is a dipole with an additional wire behind it (reflector) and an additional wire in front of it (director).

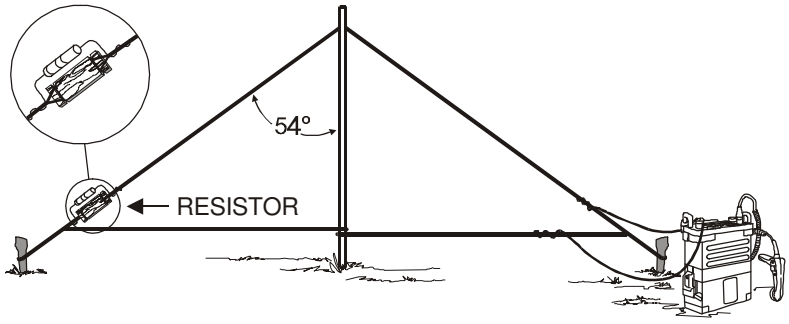

Figure 6-10. Vertical Half-Rhombic Antenna.

These additional wires increase the power to the front of the antenna while decreasing the power to the rear.

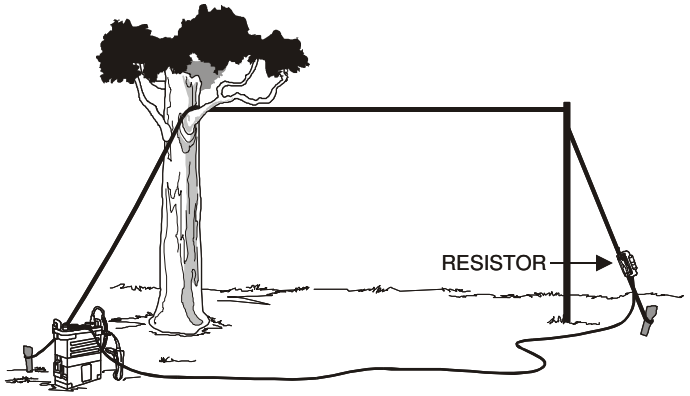

Figure 6-11. Long Wire Antenna.

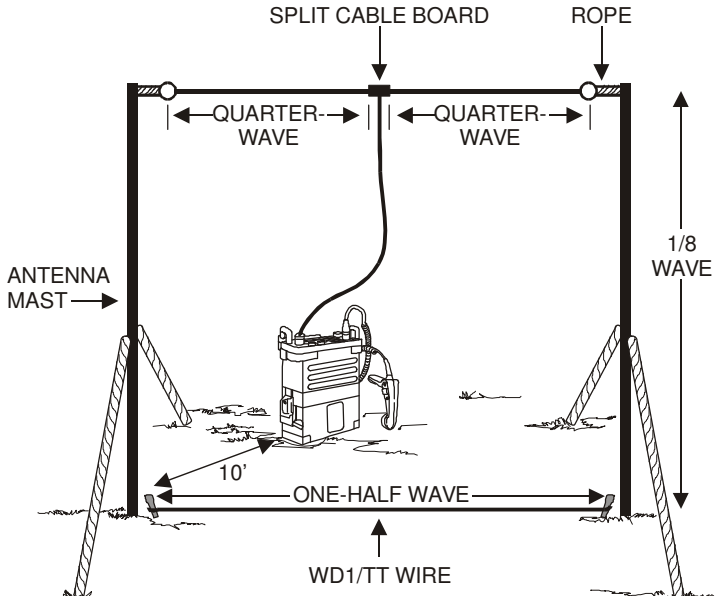

Figure 6-12. Yagi Antenna.

Vee Antenna

The vee antenna is another field expedient, directional antenna. It consists of two wires forming a vee with the open area of the vee pointing in the desired direction of transmission or reception (see fig. 6-13). The antenna must be fed by a balanced transmission line.

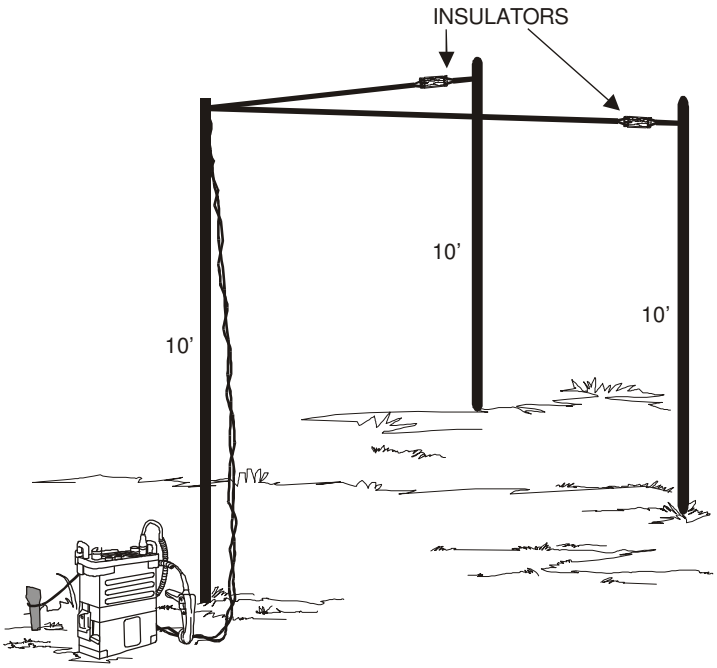

Figure 6-13. Vee Antenna.

Sloping Vee Antenna

To simplify construction, the legs may slope downward from the apex of the vee (this is called a sloping vee antenna [see fig. 6-14]).

The angle between the legs varies with the length of the legs in order to achieve maximum performance.

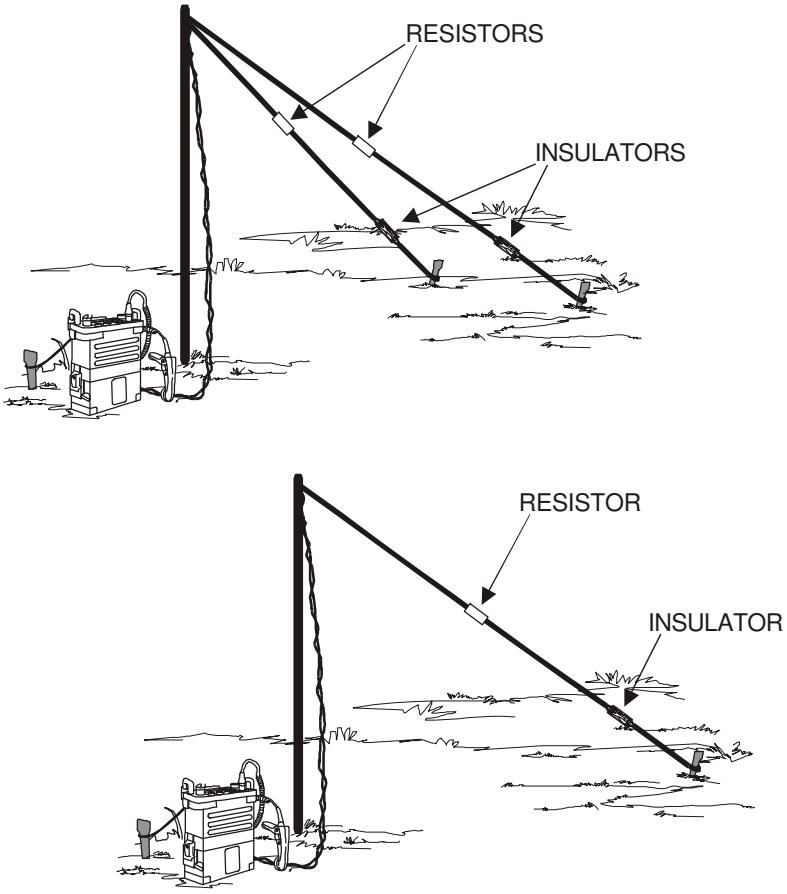

Figure 6-14. Sloping Vee Antenna.

Use table 6-1 to determine the angle and length of the legs..

Table 6-1. Leg Length and Angle for Vee Antennas.

Antenna Length (Wavelength)	Optimum Apex Angle (Degrees)
1	90
2	70
3	58
4	50
6	40
8	35
10	33

When the antenna is used with more than one frequency or one wavelength, use an apex angle that is midway between the extreme angles determined by the chart.

To make the antenna radiate in only one direction, add noninductive terminating resistors from the end of each leg (not at the apex) to ground. The resistors should be approximately 500 ohms and have a power rating at least one-half of the transmitter's output. Without the resistors, the antenna radiates bidirectionally, both front and back.

Chapter 7

Satellite Communications Antennas

The Marine Corps' primary LOS and SATCOM radio set, the AN/PSC-5 enhanced manpack UHF terminal, operates at 5 to 25 kHz and provides data and voice communications. It replaces all man-packable and vehicular-mounted UHF SATCOM radios. The AN/PSC-5 provides LOS communications with the AS-3566 and long-range SATCOM with the AS-3567 and AS-3568 antennas.

Characteristics of the AS-3566 (fig. 7-1) are—

Frequency range (LOS):	**30 to 400 MHz**
Demand assignment multiple access (DAMA):	**225 to 400 MHz**
Non-DAMA:	**225 to 400 MHz**
Polarization:	**Directional**
Power capability:	**Determined by terminating resistor**
Radiation pattern Azimuthal (bearing):	**Directional**

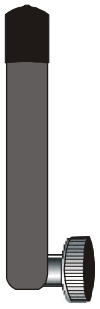

Figure 7-1. AS-3566 Low-Gain Antenna.

Characteristics of the AS-3567 (fig. 7-2) are—

Frequency range:	**225 to 399.995 MHz**
Beamwidth:	**85°**
Orientation:	**Directional**
	Elevation (0 to 90°)
Input impedance:	**50 ohms**
VSWR:	**1.5:1**
Gain:	**6 dB (225 to 318 MHz)**
	5 dB (318 to 399.995 MHz)

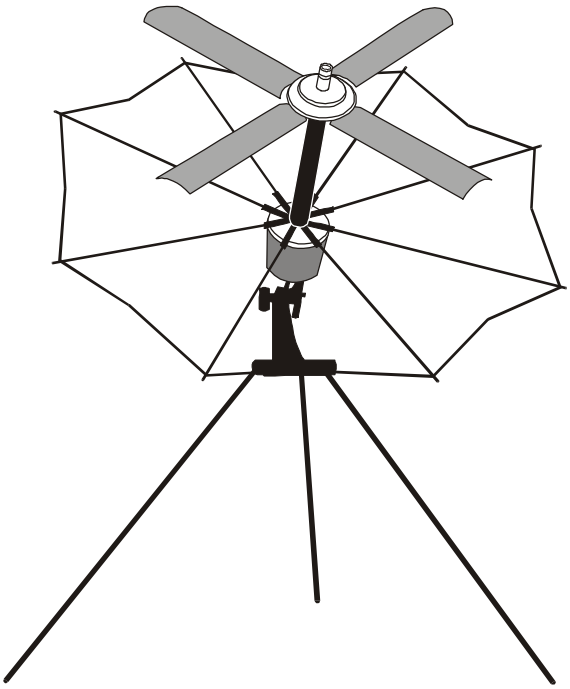

Figure 7-2. AS-3567 Medium-Gain Antenna.

Characteristics of the AS-3568 (fig. 7-3) are—

Frequency range:	**240 to 400 MHz**
Beamwidth:	**77°**
Orientation:	**Directional**
	Elevation (0 to 90°)
	Azimuth: ± 180°
Imput impedance:	**50 ohms**
VSWR:	**1.5:1 maximum**
Gain:	**8 dB (240 to 318 MHz)**
	6 dB (318 to 400 MHz)
Power	**Up to 150 watts continuous**

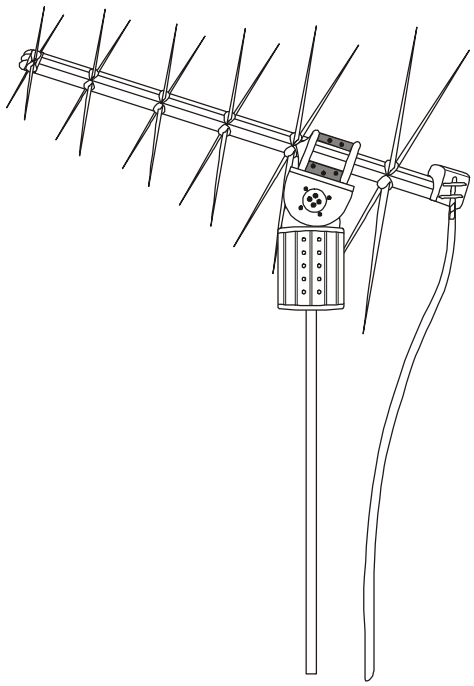

Figure 7-3. AS-3568 High-Gain Antenna.

SITING SATCOM ANTENNAS

The most important consideration in siting LOS SATCOM equipment is the antenna elevation with respect to the path terrain. Choose sites that exploit natural elevations.

Considerations

The most important consideration in siting over-the-horizon systems is the antenna horizon angles (screening angles) at the terminals. As the horizon angle increases, the transmission loss increases, resulting in a weaker received signal.

The effect of the horizon angle on transmission loss is very significant. Except where the consideration of one or more other factors outweighs the effect of horizon angles, the site with the most negative angle should be first choice. If no sites with negative angles exist, the site with the smallest positive angle should be the first choice.

Determining Horizon Angles

The horizon angle can be determined by using a transit at each site and sighting along the circuit path. Strictly speaking, the on-site survey will determine the visual horizon angle. The radio horizon angle is slightly different from the visual horizon angle; however, the difference is generally insignificant.

The horizon angle is measured between the tangent at the exact location of the antenna and a direct LOS to the horizon. The tangent line is at a right angle (90°) to a plumb line at the antenna site. If the LOS to the horizon is below the tangent line, the horizon angle is negative.

Trees, buildings, hills, or the Earth can block a portion of the UHF signal, causing an obstruction loss. To avoid signal loss due to obstruction and shielding, clearance is required between the direct LOS and the terrain. Path profile plots are used to determine if there is adequate clearance in LOS systems.

Weak or distorted signals may result if the SATCOM set is operated near steel bridges, water towers, power lines, or power units. The presence of congested air-traffic conditions in the proximity of microwave equipment can result in significant signal fading, particularly when a nondiversity mode is employed.

(reverse blank)

Chapter 8

Antenna Farms

The antenna farm (also referred to as the radio hill or the antenna hill) is a component of a command echelon. It is the location of the bulk of the unit's antennas and radio and cryptographic equipment. It is also the portion of the command echelon that produces the majority of the electromagnetic radiation. Antenna farms can be located in several different areas: inside the command echelon, outside the command echelon but near it, or outside the command echelon but far from it.

COMMAND POST

The commander exercises command and control through establishing a command post (CP). CPs provide the headquarters facilities from which the commander and staff operate. Battalions and larger units may divide the headquarters into three echelons—tactical, main, and rear. The CP then becomes the echelon at which the commander is physically located.

Tactical

The tactical echelon (main group) is a mobile unit that contains a minimal personnel and equipment. Its main focus is tactical control of current operations. The antenna farm will generally be located within the CP.

Main

The main echelon is where the commander is normally located together with those elements of the staff required to plan and direct operations and control forces. The antenna farm will generally be located outside of and far from the CP.

Rear

The rear echelon, located to the rear of the main echelon, focuses on administrative and logistics functions. It is normally established by regiments and larger units. It may be located in or near the rear echelon of the senior headquarters or remain aboard ship. The antenna farm will generally be located outside of and far from the CP.

LOCATION SELECTION CONSIDERATIONS

There are doctrinal, tactical, and technical considerations involved in deciding of how far the antenna farm should be from the CP. The CIS officer and CIS chief need to list considerations relevant to the situation before determining the best location for the antenna farm.

Doctrinal Considerations

MCWP 6-2 (under development), *MAGTF Command and Control,* FMFM 6 (MCWP 3-1 under development), *Ground Combat Operations*, and MCWP 6-22, *Communications and Information Systems*, contain Marine Corps doctrinal guidance on command echelon organization and location.

Some areas to consider when deciding on the antenna farm location are communications, electronic warfare (EW), tactical situation, and accessibility.

Communications

- Take a radio along on reconnaissance to ensure that communication from the proposed site is possible.
- Choose another site if communication is not possible.

Electronic Warfare

- Enemy capability.
- Projected electronic signature of the command.

Tactical Situation

- Cover and concealment.
- Offense/defense.
- Moving/static.
- Intended length of stay.
- Future operational plans.
- Speed of displacement.

Accessibility

- Terrain.
- Climate.
- Personnel and equipment available.

Tactical Considerations

Once the doctrinal issues have been addressed, locating the antenna farm must be reviewed in the light of tactical considerations. Since the antenna farm contains the majority of the unit's radios, cryptographic equipment, antennas, and a fair portion of the radio operators, the physical safety of the site is an important aspect of the

antenna farm location decision. At the division/force service support group/wing levels, the antenna farm should be remoted 1,000 meters away from the CP, if possible.

Security. The antenna's physical security depends on the ability to protect it. The requirement to provide protection depends on the considerations listed above. Protection considerations also depend, in part, on the proximity of the antenna farm to the CP. For an antenna within the CP, no additional protective measures are required beyond those employed to protect the CP. Additional considerations for the antenna farms located at remote sites follow.

Far Remote Sites

- Security forces available.
- Natural obstacles.
- Perimeter defense, avenues of approach.
- Barbed wire, automatic weapons, deployment.
- Mines and sensors.
- Supporting coverage.

Near Remote Sites

- Same factors as above apply.
- Take increased EW measures.
- Enforce strict circuit discipline.
- Use messengers.

Cover and Concealment. Whether the antenna farm is located inside the unit perimeter or at a remote location, using cover and concealment is imperative. Security assets make it possible to select a site that has the best available cover and concealment. Cover and concealment is a trade-off with the ability to communicate with and

from the site. A thoroughly covered and concealed site that prevents communications is worthless.

Obstacles. As with any other defensive position, use natural or manmade obstacles to enhance the antenna farm's security.

Terrain. Studying the terrain in the vicinity of remote antenna farms is essential to developing an adequate plan for defense. Studying the terrain is also of paramount importance to ensuring that a unit can communicate from the site.

Technical Considerations

Siting VHF antennas greatly effects communications reliability. In an ideal setting, the antenna would be as high as possible above a flat, clear area. In tactical situations, the antenna location must be a compromise of propagation consideration, EW considerations, and cover and concealment.

When it is possible to see the distant station but not communicate with it, the receiving station is experiencing destructive multipath interference. This combining of direct and reflected rays out of phase, results in complete signal cancellation. This interference can also result in a very weak signal or one that flutters. To improve communications, either raise or lower the antenna or move the antenna to several different sites. Usually, one or both of these actions will result in good communications.

Another cause of weak communications is antenna cross-polarization. This means that the transmitting and receiving antennas have a different polarization. For best communications, both antennas should be vertically or horizontally polarized.

Another problem could be misaligned directional antennas. If directional antennas are not correctly pointed at each other, communication is degraded. The directional antennas' electrical characteristics can change over several field deployments, especially if the antenna is subjected to harsh use. These electrical characteristic changes can cause the radiation pattern to change. Then, when the antenna is physically pointed at the distant station, the main radiation may be aimed in another direction.

To correct these electrical characteristic changes, have the distant station transmit. Slowly turn the receiving antenna while listening to the received signal. When the received signal is strongest, the antenna is properly aligned for the circuit. Secure the antenna in this position and have the distant station align its antenna in the same way. When both antennas are properly adjusted, the maximum radiation from each antenna is directed at the other antenna.

SITING VHF ANTENNAS

Antenna sites should be as high as possible and clear of obstructions such as hills, dense woods, and buildings. If it is necessary to site the antennas on or around hills, choose a site that allows LOS to the distant station or stations. If possible, place the antenna on the military crest of a hill, *not* on the ridge line. Antennas located on the ridge line provide an aiming stake for enemy observation and fire (fig. 8-1).

Place high ground between the antenna and the enemy to block the enemy's observation and the antenna's radiation, reducing the enemy's intercept capability (fig. 8-2).

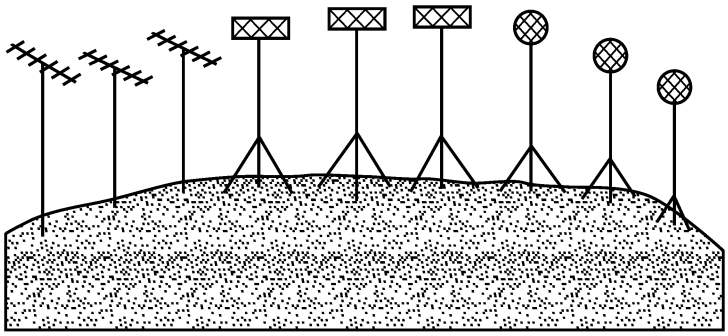

Figure 8-1. Ridge Line Antenna Farm.

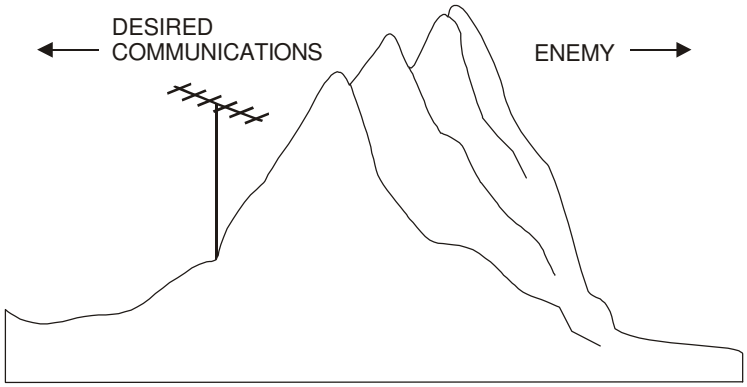

Figure 8-2. Antenna Sited on a Military Crest.

In a dense forest, get the antenna tip above the treetops. This height allows the radio signal to propagate in the clear space above the trees. If it is impossible to raise the antenna above the trees, a horizontally polarized antenna provides better communications through

trees than a vertically polarized antenna. Figure 8-3 shows good, fair, and poor antenna siting in dense trees.

A clearing in a forest improves propagation if the antenna is placed so that the clearing is between the antenna and the distant station (for a directional antenna). Place an omnidirectional antenna in the center of a clearing, with the antenna as high as possible (fig. 8-4).

A communicator may have little choice in selecting a transmitter or receiver site location. Often the site is determined by the operational requirements of a superior command. However, when a choice is available, determine the HF antenna site by wave-path geometry.

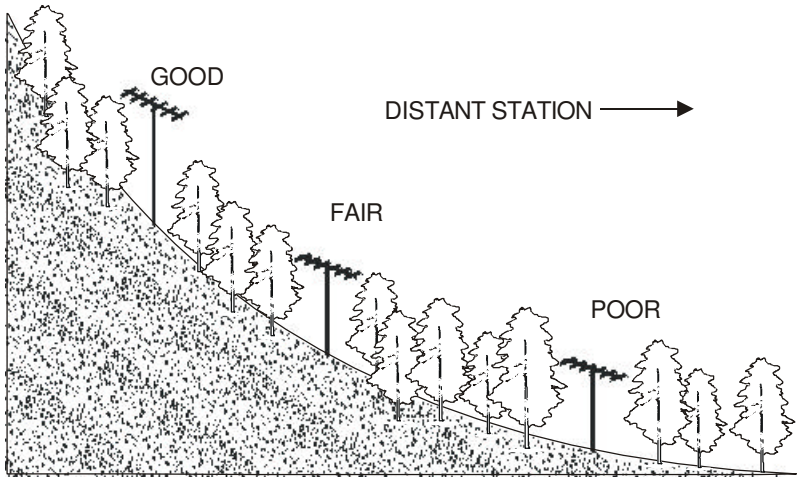

Figure 8-3. Antennas Sited in Dense Trees.

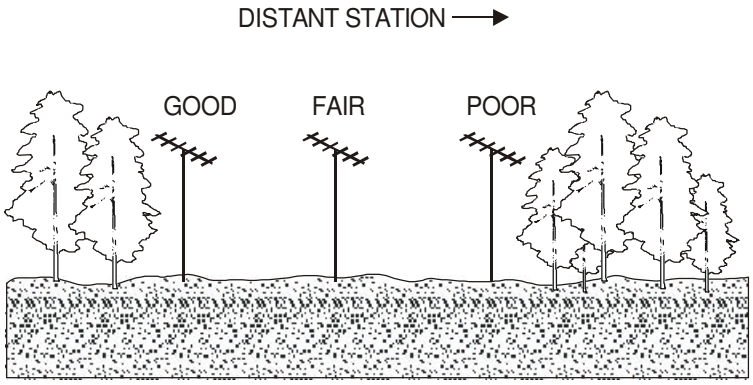

Figure 8-4. Directional Antennas Sited in a Clearing.

Transmitting Antenna Site

Any site that has a horizon whose obstructions subtend vertical angles of less than 2° from level in any of the directions of transmission can be considered immediately as a satisfactory site from the standpoint of radiation. As a simple rule, a satisfactory horizon clearance exists when any obstruction subtends a vertical angle that does not exceed one-half of the desired beam angle in the vertical plane in that direction. If the vertical beam angle for a given circuit is low for the lowest order hop, then the horizon in that direction can be as much as 5° above level as seen from the antenna location.

In hilly or mountainous country, choosing a site for long-distance transmission, requiring very low beam angles, can be difficult. When the only possible site presents horizon obstructions in the preferred wave path, it may be necessary to design an antenna that uses a higher order of hop, and to direct the beam at a corresponding higher angle to obtain the desired 2-to-1 horizon clearance angle.

For example, if the computed vertical beam angle for a one-hop circuit is 6° at an azimuth of 332°, and the horizon in this direction is a range of mountains with a height of 8° as seen from the antenna site, the performance of the circuit would be greatly compromised by the obstruction of the mountains. It might be better to work this circuit with two hops—a vertical beam of 20° could be used instead, with adequate horizon clearance for the wave path. If the circuit required 6° for a two-hop circuit 5,400 kilometers long with the same obstruction sited, the circuit could be changed to three hops, which, for the same layer heights, would permit using a beam at 14°. The latter solution lacks the full 2-to-1 horizon-clearance angle, but it may be an acceptable compromise and perhaps preferable to using four hops.

Short-range, sky wave circuits using one-hop high-angle radiation give a great latitude in the choice of sites. For F layer transmission to distances of 500 miles and less, the vertical beam or angles are always greater than 30°. Satisfactory sites for such transmission can often be located in rather deep valleys without any compromise on the circuit performance.

Forests on or near the site require some consideration. Because the theoretical radiation pattern is calculated on perfect reflectivity from ground, some precautions are necessary to obtain actual performance that substantially agrees with theoretical performance. Choose a site that provides conditions as nearly perfect as possible with respect to wave-reflecting surfaces around the antenna. There should be few or no trees and buildings out to the necessary distance from the antenna. The point of wave reflection should be flat and cleared. An excellent choice is a site that borders the sea or a lake. Water is a wave-reflecting surface.

Receiving Antenna Sites

Choosing a receiving antenna site is similar to choosing a transmitting antenna site. The dominant angles of arrival of the incoming waves at the site are determined mainly by the characteristics of the transmitting antenna. Best results are obtained with complementary transmitting and receiving antennas. If a horizon obstruction exists at the optimum angle of wave arrival, a compromise, noncomplementary antenna may be necessary. When possible, move the transmitting antenna to align with the receiving antenna.

The receiving site must be as free as possible from electrical noise. The tolerable amount of manmade noise at a particular receiving station site depends on the prevailing natural atmospheric noise levels. At a well selected site, reception should always be limited only by natural atmospheric noise. Any manmade noise at the site should always be substantially less than the atmospheric noise received during the low-noise periods.

Aside from broadcast systems, most communications systems require that antennas be positioned so that their main lobes of radiation are aligned with each other. This requires knowledge of the great circle bearing to the other antenna and the local magnetic variation from true north.

The great circle bearing between two locations is calculated by methods that are beyond the scope of this publication. A way to find the great circle bearings is to request a frequencies of optimum transmission chart from the Electromagnetic Compatibility Analysis Center.

ANTENNA FARM INTERNAL ARRANGEMENT

Frequency Band

The higher the frequency, the shorter the wavelength. The shorter the wavelength, the more nearly LOS. The more nearly LOS, the more critical is a clear LOS path for the signal.

Antenna Selection and Placement

Selection. The key to antenna selection rests with the answers to the following three questions:

- **To whom will you be transmitting? Where will they be?**
- **What is the path between you and them?**
- **What kind of net? Point-to-point or multistation?**

Placement. Antenna placement within the antenna farm should take into account the following three factors:

Cosite Interference. **Evaluating interference can be difficult because of the nature of the systems involved and the complexity of the signals. The mechanisms are varied. In the simpler cases they may be direct interference into the radio receiver. In other cases, they may be spurious products or combinations of products which arrive at the receiver input and produce a net resultant interference into the receiver intermediate frequency section. The latter may be frequency translations resulting from sum and difference products within the same system. In still other cases, the receiver may see an identical signal to the regular signal.**

Interference produces beats or noise in a radio receiver which have detrimental effects depending on the frequency, deviation, channel separation and linearity of the transmission medium, as well as the

nature of the interfering signal. Sometimes the interfering signals combine with other frequencies in the system, including carrier-sum and difference frequencies, to produce interference in a third radio channel. The products may hold up automatic gain control during critical fading periods, with serious effect on system noise. Usually, noise in the base band channels is an end product.

Radio system interference may be introduced through antennas, wave guides, cabling, or by spurious products produced in the radio equipment itself. Interference introduced into the cabling or in the equipment can be prevented by good installation practices, including proper separation of high- and low-level cabling, proper grounding practices, shielding where necessary, and good equipment design and assembly. Interference introduced by coupling between wave guides in the same station is usually produced by radiation from wave guide and filter flanges which are not properly tightened, or which are damaged and cannot be mated properly.

Antenna Coupling. Antenna coupling is a frequency-independent problem that may occur whenever other antennas (whether transmitting or not) or metallic objects are located within one wave of the transmitting antenna. Antenna coupling may be either beneficial or detrimental. Yagis, log periodic arrays, and half-square antennas, for example, derive their gain and directivity from antenna coupling. Unintended antenna coupling, on the other hand, may significantly reduce the signal strength in the desired direction and either degrade or stop communications.

Coupling is based on two principles. One, that current flowing through a wire creates a magnetic field around it; and, two, that signals in phase reinforce each other whereas signals out of phase cancel each other. Receiving antennas have current flowing in them (the received signal). Because there is a flowing current that creates a magnetic field, a receiving antenna will simultaneously receive and reradiate the same signal. Receiving antennas, in fact, tend to

reradiate about one-half of the power they receive. If the receiving antenna is within one wavelength of a transmitting antenna (it makes absolutely no difference whether or not the receiving antenna's radio is tuned to the same frequency as the transmitting radio), the receiving antenna will reradiate a portion of the signal which may be out of phase with the original signal, altering the transmitting antenna's radiation pattern.

Direction of Desired Transmission. **Separate antennas according to the direction of desired transmission. For example: If antenna A is used to communicate to the east, and antenna B is used to communicate to the north, then locate antenna A south and east of antenna B.** ***Do not*** **make the signal from one antenna pass through, or around, another antenna on the way to its intended receiver. Accomplish this by the physical location of the antennas, by masking the antennas, or by placing the antennas at different elevations.**

Requirements

Separate antennas based on the frequencies at which they will operate and the power they will transmit to avoid cosite interference.

For a 10 percent separation—

Power	Distance (Meters)
1 kilowatt	500
400 watts	315
150 watts	200
100 watts	150
40 watts	100
20 watts	70
10 watts	50
2 watts	22
1 watt	15

Multiply separations by 10 for each halving of frequency separation (i.e., 10 for 5 percent; 100 for 2.5 percent).

For a 5 percent separation—

Power (Watts)	Distance (Meters)
10	500
2	220
1	150

For a 2.5 percent separation—

Power (Watts)	Distance (Meters)
10	5000
2	2200
1	1500

Separate antennas by a minimum of wavelength at the lowest frequency at which they will operate to alleviate antenna coupling.

Band	Lowest Frequency (MHz)	Minimum Separation (Feet)
HF	2	492
VHF	30	32.8
UHF	225	4.37

Separate antennas according to the desired direction of transmission (i.e., don't send the propagated wave through other antennas).

Polarization

The preferable polarization with respect to vegetation depends on the forest and the amount of foliage. Use a polarization with an inherent advantage when heavy vegetation cannot be avoided. Any

advantage based on polarization will be determined by the polarization of possible sources of interference. In deciduous forests the sources are evenly divided between vertical and horizontal. In mature coniferous forests the sources are predominately vertical, so horizontal polarization has an advantage.

Power and Signal Lines

Distribute power and signal lines to eliminate and avoid crossovers. If power and signal lines must cross, arrange them so that they cross at right angles, and separate them by 4 feet of elevation. Do not run power and signal lines parallel to each other.

ANTENNA FARM LAYOUT PRINCIPLES

- Segregate HF, VHF, and UHF channels.
- Maintain separation between antennas.
- Separate power and signal lines. Keep them out of the main ground phase of antennas.
- Keep transmitters close to the feed point of their antennas (i.e., keep them short).
- Establish good RF and safety grounds for each antenna.
- Use ground radials for each antenna.
- Site LOS antennas on the highest ground.
- Site antennas to avoid the main lobes and significant side lobes of directional antennas.
- Remote antenna farms 1 kilometer from the CP if practical.

Section II
Definitions

A

alternating current—Current that is continually changing in magnitude and periodically in direction from a zero reference level. Also called AC.

amplification—The process of increasing the strength (current, voltage, or power) of a signal.

amplitude—The level of an audio or other signal in voltage or current. The magnitude of variation in a changing quantity from its zero value.

amplitude modulation—Modulation in which the amplitude of the carrier wave is varied above and below its normal value in accordance with the intelligence of the signal being transmitted. Also called AM.

angle of incidence—The acute angle (smaller angle) at which a wave of energy strikes an object or penetrates a layer of the atmosphere or ionosphere.

antenna—A device used to radiate or receive electromagnetic energy (generally RF).

antenna bandwidth—The frequency range over which a given antenna will accept signals.

antenna feed—Means by which power is transferred to and from the antenna and the connecting transmission line.

antenna gain—The effectiveness of a directional antenna as compared to a standard nondirection antenna. It is usually expressed as the ratio in decibels of standard antenna input power to directional antenna input power that will produce the same field strength in the desired direction. For a receiving antenna, the ratio of signal power values produced at the receiver input terminals is used. The more directional an antenna is, the higher is its gain.

array—Several simple antennas, usually dipoles, used together to control the direction in which most of the antenna's power is radiated.

attenuation—Power loss resulting from conductor resistance and dielectric loss within the insulating material used to separate the conductors.

azimuth—An angle measured in a horizontal plane from a known reference point.

B

balanced antenna—An antenna is balanced with respect to ground when both its arms have the same electrical relationship to ground.

balanced transmission line—A transmission line whose conductors have voltages of opposite polarity and equal magnitude with respect to the Earth.

balun—A device for feeding a balanced load with an unbalanced line, or vice versa.

bandwidth—The width of a band of frequencies used for a particular purpose.

baud—The number of times per second the carrier signal changes value.

bidirectional—In two directions, usually opposite.

blob—Small areas of the atmosphere where temperatures and pressure differences produce conditions suitable for the refraction of radio waves.

broadband antenna—An antenna capable of operation over a wide band of frequencies

C

cable connectors—Fittings for cable ends which permit rapid connection and disconnection with equipment or other cables.

capacitance—A natural property of an electrical circuit which opposes the rate of change of voltage.

capacitor—A device for storing electrical charge.

center-fed—Transmission line connection at the electrical center of an antenna radiator.

coaxial cable—A transmission line consisting of two conductors, one inside the other, and separated by insulating material. The inner conductor may be a small copper tube or wire; the outer conductor may be metallic tubing or braid. Radiation loss from this type of line is very little.

command post—The headquarters of a unit or subunit where the commander and staff perform their functions.

communications circuit—The means by which information is transferred between two or more places.

conductor—A material (usually metal) that has low resistance to the flow of electrical current. A wire, cable, or other object capable of carrying electric current. Good conductors are made of metals such as silver, copper, and aluminum.

connections—Points at which two or more conductors are brought into contact.

counterpoise—A conductor or system of conductors used as a substitute for ground in an antenna system; a wire or group of wires mounted close to the ground, but insulated from ground, to form a low-impedance, high-capacitance path to ground.

critical frequency—The highest frequency at which a signal may be transmitted directly overhead and be reflected back to Earth from the ionosphere.

cross-polarized—The polarization of a received signal is 90 degrees to the polarization of the receiving antenna.

current—The flow of electrons along any path.

D

decibel—The standard unit used to express transmission gain or loss and relative power levels. Also called dB.

deflection—The displacement of an electron beam from its line of sight path.

demodulate—To recover the information originally impressed on the radio wave.

dielectric—A material that does not conduct electricity, such as rubber or glass, i.e. an insulator.

diffraction—The process by which electromagnetic waves are bent so that they appear behind an obstruction.

dipole antenna—A center-fed wire antenna whose conductors are in a straight line.

directional antenna—An antenna designed to transmit and receive RF energy in a specific direction(s).

direct waves—Waves which propagate in a straight line from the transmitting to the receiving antennas.

directivity—The property of radiating more energy in some directions than in others.

director—A conductor placed in front of a driven element to cause directivity.

ducting—The propagation of VHF/UHF wave by bouncing between the Earth's surface and the interface between layers of air having different dielectric constants.

E

efficiency—The ratio of power output to power input.

electromagnetic field—The field of force that an electrical current produces around the conductor through which it flows.

electromagnetic waves—A wave propagating as a periodic disturbance of the electric and magnetic fields and having a frequency in

the electromagnetic spectrum; the means by which energy is transmitted from one place to another.

end-fed—An antenna whose power is applied to one end rather than at some point between the ends.

F

fading— A periodic decrease in received signal strength.

feedpoint impedance—Impedance that is measured at the input terminals of an electrical device such as an antenna.

fields—Regions in which each point has a value of a physical quantity (voltage, magnetic force, velocity, mass, etc.).

free space—The absence of ground.

frequency—The rate at which a process repeats itself. In radio communications, frequency is expressed in cycles per second.

frequency hopping—A method of jumping from frequency to frequency in synchronization with one another in a random order at a rate of up to 100 times per second. Frequency hopping is the preferred method of communication with SINCGARS radios.

frequency modulation—The process of varying the frequency of a carrier wave, usually with an audio frequency, in order to convey intelligence. Also called FM.

frequency of optimum transmission—85 percent of the maximum usable frequency (MUF). A practical frequency selection which allows for MUF variations.

G

gain—The increase in signal strength that is produced by an amplifirer.

generator—A device that changes mechanical energy into electrical energy.

ground—A very large semiconductive surface (the Earth) or a smaller highly conductive surface.

ground radials—Wires on or in the earth to improve its conductivity near the antenna.

ground screen—A wire mesh ground plane.

ground wave—A radio wave that travels along the Earth's surface rather than through the upper atmosphere.

H

half-wave dipole antenna—A center-fed antenna whose electrical length is half the wavelength of the transmitter or received signal.

half-wave vertical dipole antenna—A half-wave dipole constructed vertical to the Earth's surface.

hertz—One cycle per second.

high frequency—frequencies between 3 and 30 MHz.

hop—A single reflection of the wave back to Earth at a point beyond the horizon.

horizontal dipole—A dipole constructed parallel to the Earth's surface.

horizontal pattern—The horizontal cross-section of an antenna's three-dimensional radiation pattern.

horizontal polarization—Transmission of radio waves in such a way that the electric lines of force are horizontal (parallel to the Earth's surface).

I

impedance—The total opposition offered by a circuit or component to the flow of alternating current.

impedance match—The condition where the load impedance equals the characteristic impedance of a transmission line.

inductance—The natural property of an electrical circuit which opposes the rate of change or current, i.e., electrical "intertia."

in phase—Two or more signals of the same frequency passing through their maximum and minimum values of like polarity at the same instant.

insulator—A device or material that has a high electrical resistance; a nonconductor of electricity.

interference—A degradation of a received signal caused by another transmitter, a noise source, or the desired signal propagation over two or more different routes.

inverted L antenna—A half-wave dipole fed by a one-quarter wavelength long vertical section.

inverted vee antenna—A half-wave dipole erected in the form of an upside-down vee, with the feed point at the apex. It is essentially omnidirectional, and is sometimes called a "dropping doublet."

ionization—The process where radiation and particles from the Sun make some of the Earth's atmosphere partially conductive.

ionosphere—A partially conducting region of the Earth's atmosphere between 50 kms and 400 kms high.

L

lambda—Greek lower case letter (λ) used to represent a wavelength with reference to electrical dimensions in antenna work.

linearly polarized antennas—Antennas that produce only one polarization.

line of sight—The transmission path of a wave that travels directly from the transmitting antenna to the receiving antenna. Also called LOS.

load—A device that consumes electrical power.

loading—Providing or connecting an electrical device capable of accepting power to match the impedance of an antenna to a transmitter so that maximum power is radiated from a generating device, such as a transmitter.

lobe—A bulge on an antenna radiation pattern which indicates the direction in which radiated power is concentrated.

long-wire antenna—An end-fed single wire antenna usually one wavelength or longer.

lowest usable frequency—The lowest frequency that will not be absorbed by the ionosphere or smothered by atmospheric noise. Also called LUF.

M

maximum usable frequency—The highest frequency for a given elevation angle that will reflect from an ionospheric layer. Also called MUF.

megahertz—One million cycles per second. Also called MHz.

modulate—To change the output of a transmitter in amplitude phase, or frequency in accordance with the information to be transmitted.

monopole antenna—An antenna with a single radiating element; a whip antenna.

N

noise—Random pulses of electromagnetic energy generated by lightning or electrical equipment.

O

offset angle—The angle at which a long wire antenna must be aimed on either side of the direction to the base station.

omnidirectional antenna—An antenna whose radiation pattern shows equal radiation in all horizontal directions.

oscillation—A periodic, repetitive motion or set of values (voltage, current, velocity).

out of phase—Two alternating quantities not passing through corresponding values at the same time (e.g., if the current in a circuit reaches its maximum value before or after the applied voltage does, the current is out of phase with the voltage).

P

path loss—The ratio of received power to transmitted power.

polarization—The direction of the electric field of a radiated wave relative to the surface of the Earth (vertical, horizontal, linear, and circular).

polarization fading—Fading due to polarization rotation of a received signal. The received signal decreases when the incoming wave does not have the same polarization as the receiving antenna.

power gain—The directive gain of an antenna multiplied by its efficiency

propagation—A phenomenon by which any wave moves from one point to another; the travel of electromagnetic waves through space of along a transmission line.

propagation path—The path or route over which power flows from the transmitter to the receiver.

Q

quarter-wave antenna—An antenna with an electrical length that is equal to one-quarter wavelength of the signal being transmitter or received.

R

radiate—To transmit RF energy.

radiation—Energy that moves through space as electromagnetic waves.

radiation patterns—A chart of relative radiation intensity (or power) versus direction.

radio frequency—Any frequency of electrical energy capable of propagation into space (usually above 20 kHz). Also called RF.

radio horizon—The greatest distance on the Earth at which a transmitted wave can be received by the direct path from a transmitter located on the Earth.

radio waves—Electromagnetic waves at a frequency lower than 3,000 GHz and propagated through space without and artificial guide.

receiver—Amplifying and selecting equipment that receives radio frequencies and delivers a duplicate of the information impressed on the transmitter.

reception—The process of recovering transmitted information; the process of converting electromagnetic fields to current in wires.

reciprocity—The various properties of an anntenna apply equally whether the antenna is transmitting or receiving.

reflected waves—Waves that change their direction of propagation after striking a surface that is either a conductor or an insulator.

reflection—The turning back of a radio wave from an object or the surface of the Earth.

reflector type antenna—An antenna placed in front of a conducting surface (reflector) for the purpose of increasing radiation in one direction, at the expense of radiation in other directions.

refraction—The bending, or changing direction, of a radio wave passing into or through layers of the atmosphere or the ionosphere that have different density (dielectric constant).

refractive index—A measure of the degree by which the speed of an electromagnetic wave is slowed as it propagates through a given material.

resistance—The property of a material or substance to oppose the passage of current through it, thus causing electrical energy to be converted into heat energy.

resonance—The state or frequency of vibration, electrical or mechanical, in which forces that impede the motion are minimum.

resonant length—The proper length of an antenna to render it resonant

rhombic antenna—An antenna made of four wires of equal length connected together in the shape of a rhombus.

S

scattering—The spreading or breaking up of electromagnetic waves when they encounter objects of different electrical properties than those in which the wave is traveling.

shortened dipole—A dipole antenna made to resonate at a lower frequency by use of a coil.

signal—A radio wave that contains the transmitted message.

signal loss—The amount of signal power lost between the transmitter and receiver.

signal-to-noise ratio—The power intensity of the signal compared to that of the noise.

skip distance—The distances on the Earth's surface between the points where a radio wave sky wave leaves the antenna and is successfully reflected and/or refracted back to Earth from the ionosphere.

skip zone—The space or region within the transmission range where signals from a transmitter are not received, i.e., between the ground wave and the point where the refracted wave returns.

sky wave—A radio wave that is reflected from the ionosphere.

sloping long-wire antenna—A wire antenna of length greater than one wave-length and supported in an inclined orientation with respect to the ground.

standing-wave ratio—The ratio of the maximum to minimum amplitudes of voltage, or current, along a transmission line.

standing waves—Waves that appear not to be moving as the result of power traveling in both directions along a transmission line.

stratosphere—The second layer of the Earth's atmosphere, extending from 10 to 50 km.

sunspots—Activity on the Sun's surface which is seen as a series of blemishes that vary in size, number, and location.

T

take-off angle—The angle measured from the Earth's surface or horizontal up to the direction of propagation towards the ionosphere.

transistor—A minute electronic device that permits a small current to control the flow of a larger current.

transmission line—A conductor that transfers radio frequency RF energy from the transmitter to the antenna or from the antenna to the receiver.

transmitter—A piece of equipment that generates and amplifies a radio frequency, adds intelligence to this signal, and then sends it out into the air as a radio frequency wave.

troposphere—The region of the Earth's atmosphere from the surface to a height of about 10 km.

tuning—The process of adjusting a radio circuit so that it resonates at the desired frequency.

twin-lead transmission line—A balanced transmission line generally used with balanced antennas.

two element array—An antenna composed of two element antennas.

U

ultrahigh frequency—Frequencies between 300 and 3,000 MHz.

unbalanced transmission line—A transmission line one of whose conductors is grounded.

unidirectional—In one direction only.

V

vee antenna—Two long-wire antennas connected to form a vee.

velocity—The speed of a radio wave through the dielectric medium it is in.

vertical dipole—A balanced or dipole antenna oriented vertically.

vertical polarization—Transmission of radio waves in such a way that the electric lines of force are vertical (perpendicular to the Earth's surface).

vertical quarter-wave antenna—A monopole (whip) antenna that is oriented vertically.

very high frequency— Frequencies between 30 and 300 MHz; transmissions that follow the line of sight path.

voltage—Electrical pressure, expressed in volts, which is the result of squeezing electrons together.

voltage standing-wave ratio—The ratio of the amplitude of the electric field or voltage at a voltage maximum to that at an adjacent voltage minimum. Also called VSWR.

W

wavelength—The distance a wave travels during one complete cycle. It is equal to the velocity divided by the frequency.

wave propagation—The transmission of RF energy through space.

whip antenna—A vertical monopole.

wire—Conductors in one of many different sizes with different kinds of insulation.

Y

yagi antenna—A combination of dipoles to increase the gain.

NATIONAL SYSTEM FOR GEOSPATIAL INTELLIGENCE

GEOSPATIAL INTELLIGENCE (GEOINT) BASIC DOCTRINE

Publication 1.0
April 2018

Approved for public release, 18-142

MESSAGE FROM THE GEOINT FUNCTIONAL MANAGER

I am pleased to present *Publication 1.0: GEOINT Basic Doctrine, 2018*, to the NSG Community. This publication serves as an introduction to GEOINT, establishes common references and terminology, and directly supports our NSG Strategic Priority "Professionalization – Inspire the Next Generation Talent."

Publication 1.0 is unique because it was created by the NSG Community and carefully crafted to avoid terms and language specific to any Agency or Service. The NSG Working Group (which included representatives from Services and Agencies that train GEOINT professionals) guided and approved all content prior to formal NSG coordination.

One contribution of Publication 1.0 is the establishment of a common, NSG-coordinated GEOINT glossary. This is a basic but very important step to achieve standardized training and certification, shared curricula, and a workforce that can provide GEOINT support in any environment. These goals are also supported by Chapter Four, which contains the first GEOINT Tradecraft Chart to map military occupations to civilian tradecraft roles.

Other key features of Publication 1.0 include:

- Reference charts for platforms and phenomenology
- User-friendly descriptions of GEOINT concepts and functions
- Introduction and definition of the term "GEOINT Enterprise"
- Definitions of GEOINT, NSG, ASG, CAC
- Charts that show members of the NSG, ASG, CAC, and GEOINT Enterprise

Finally, I am proud we were able to complete an unclassified, publically releasable document to help ensure the widest distribution and use across the NSG, ASG, and beyond.

Onward,

R T Cardillo

Robert Cardillo

INTRODUCTION

PURPOSE.

Geospatial Intelligence (GEOINT) Basic Doctrine, Publication 1.0, (hereinafter referred to as *Pub 1.0*) provides decision makers and intelligence producers a basis for understanding GEOINT to help plan and execute their assigned missions. This document also serves as a common frame of reference for the GEOINT Enterprise Community. As the highest level of doctrine for GEOINT, NSG Pub 1.0 is written at an unclassified level and in a manner that can be readily understood by consumers (non-producers) and new producers of GEOINT. Pub 1.0 also complements the doctrine, tactics, techniques, and procedures and guidance outlined in Joint Publication 2-03, *Geospatial Intelligence Support to Joint Operations*.

GEOINT doctrine is prepared under the auspices of the GEOINT Functional Manager (GFM). Executive Order (E.O.) 12333 "United States Intelligence Activities" (as amended in 2008), Section 1.3 (b) (12) (A) (iii), designates the Director of the National Geospatial-Intelligence Agency (NGA) as the GFM for the U.S. Intelligence Community (IC). The title of GFM encompasses the roles and responsibilities of the Department of Defense (DoD) GEOINT Manager, as defined in DoD Directive 5105.60 "National Geospatial-Intelligence Agency," and the IC Functional Manager for GEOINT, in accordance with applicable law and Director of National Intelligence (DNI) and DoD directives, guidance, and agreements. The GFM leads the National System for Geospatial Intelligence (NSG), as described in Chapter Five.

SCOPE.

This document supersedes *Geospatial Intelligence (GEOINT) Basic Doctrine Publication 1-0*, dated September 2006. As NSG community doctrine, it documents fundamental principles to guide the operation of the NSG and how it produces, maintains, and employs GEOINT. Pub 1.0 includes the legal definition of GEOINT, an overview of data used for GEOINT products, a basic understanding of GEOINT products, an understanding of the GEOINT professional work roles, and a description of the governance framework for the function of GEOINT. GEOINT is rapidly evolving to incorporate capabilities such as data analytics, artificial intelligence, machine learning, deep learning, and computer vision. However, these topics are beyond the scope of this introductory document.

APPLICABILITY.

Pub. 1.0 applies to the NSG, as defined in Chapter Five. It also applies to NSG Partners and the GEOINT Enterprise (also defined in Chapter Five), to the extent defined by their distinct roles. As doctrine, this publication is authoritative but not directive. It does not include policy or strategy but does serve as a foundational guide for the production, maintenance, and sustainment of GEOINT across the NSG Community.

OVERVIEW.

Chapter One presents the legal definition of GEOINT, including a description of its three complementary elements: Imagery, Imagery Intelligence, and Geospatial Information. Since the term GEOINT is used broadly to include the supporting aspects of GEOINT, the chapter also addresses areas that are critical to the function of GEOINT but not included in its definition.

Chapter Two addresses GEOINT data used to create each of the three elements of GEOINT and provides information on how that data is collected. The chapter includes a section that clearly delineates different types of collection platforms, sensors, and GEOINT phenomenologies, and lists the advantages and disadvantages of each type for various circumstances and purposes. Chapter Two also describes additional types of data used for imagery intelligence and geospatial information.

Chapter Three is focused on Products. This chapter describes how GEOINT products are developed using any combination of three types of layers—Geospatial, Mission, and Intelligence—and then explains how elevation, time, motion, and activity may be added to create a more dynamic, realistic, and comprehensive GEOINT product. For the purposes of this document, products are separated into three broad categories: Mission/Event Preparation, Assessment, and Detection. The chapter describes what each of those areas encompasses and provides multiple examples of products in each category to illustrate how they may be used to support specific mission requirements.

Chapter Four discusses GEOINT professionals and defines tradecraft areas. The chapter includes a chart with specific civilian work roles and corresponding military designations for GEOINT professionals.

Chapter Five describes the GEOINT Community, from the entire GEOINT Enterprise to its key elements such as the NSG—which includes U.S. Government GEOINT entities and activities—and the Allied System for Geospatial Intelligence (ASG). The chapter references authorities that designate the Director of NGA as the GEOINT Functional Manager and DoD GEOINT Manager, and outline GFM authorities and responsibilities. Chapter Five also describes GEOINT Community forums and the important role they play in helping the GFM to shape and guide the function of GEOINT.

Approved for public release, 18-142

CHAPTER ONE – WHAT IS GEOINT?

Geospatial Intelligence, also known as GEOINT, is defined by law in Title 10 of the U.S. Code, Section 467 (2005) as:

> **GEOINT:** "The term 'geospatial intelligence' means the exploitation and analysis of imagery and geospatial information to describe, assess, and visually depict physical features and geographically referenced activities on the earth. Geospatial intelligence consists of imagery, imagery intelligence, and geospatial information."

Section 467 also provides definitions of the three elements of GEOINT:

- **Imagery.** A likeness or presentation of any natural or man-made feature or related object or activity and the positional data acquired at the same time the likeness or representation was acquired, including products produced by space-based national intelligence reconnaissance systems and likenesses or presentations produced by satellites, airborne platforms, unmanned aerial vehicles, or other similar means.

  Imagery includes handheld photography, but, within the context of GEOINT, "does not include handheld or clandestine photography taken by or on behalf of human intelligence collection organizations."

- **Imagery Intelligence.** The technical, geographic, and intelligence information derived through the interpretation or analysis of imagery and collateral materials.

- **Geospatial Information.** Information that identifies the geographic location and characteristics of natural or constructed features and boundaries on the earth and includes: statistical data; information derived from, among other things, remote sensing, mapping, and surveying technologies; and mapping, charting, geodetic data, and related products.

Title 10 U.S. Code, Section 442: MISSIONS

This section of the U.S. Code codifies NGA's national mission and addresses systems and tasking of GEOINT. Although the language does not define GEOINT, it provides additional context about the definition and is shown below to ensure awareness. Title 10, Section 442(a)(2) states:

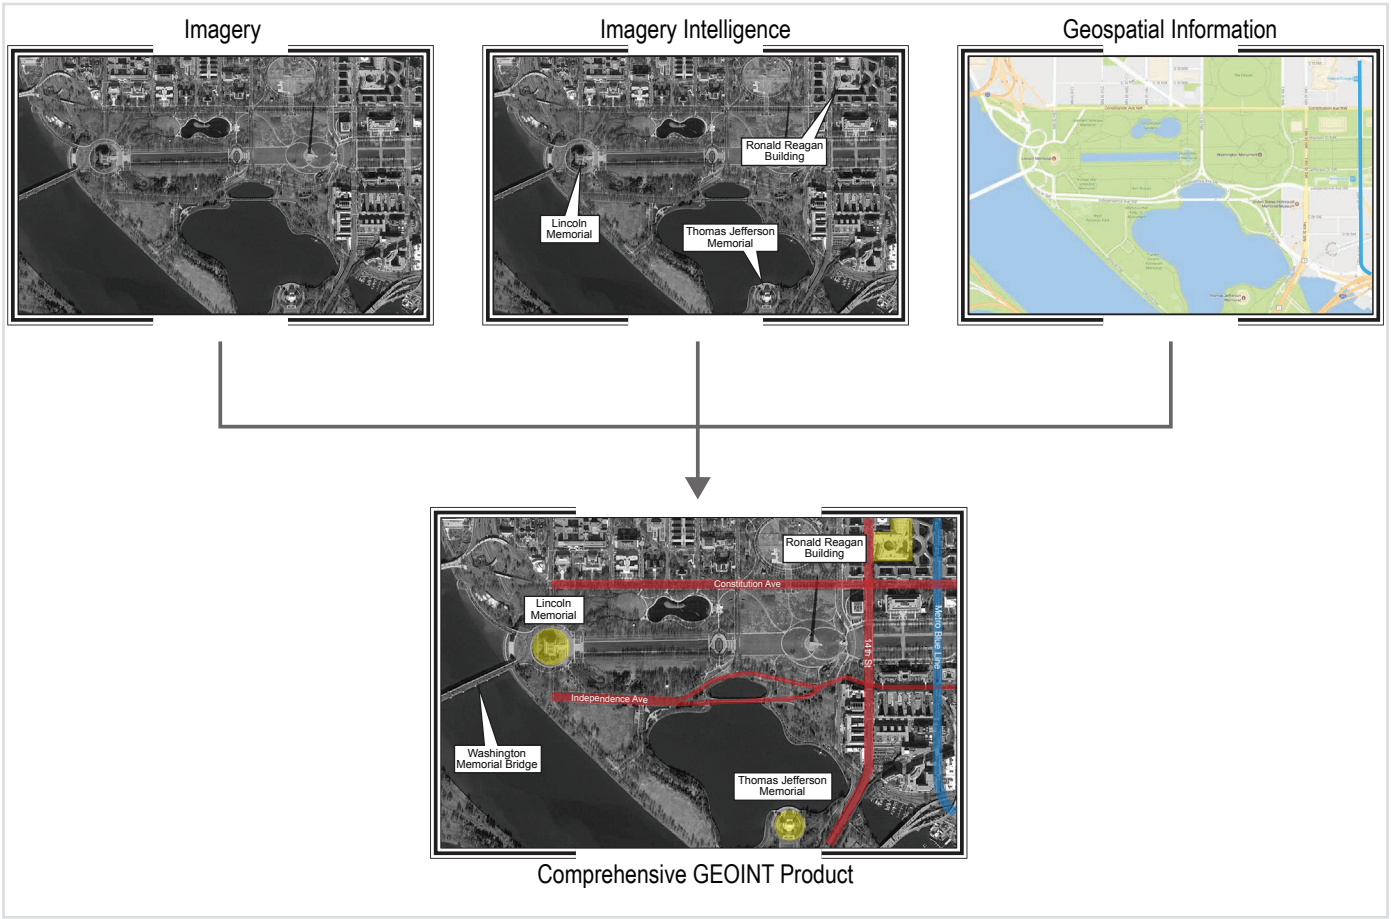
"As directed by the Director of National Intelligence, the National Geospatial-Intelligence Agency shall develop a system to facilitate the analysis, dissemination, and incorporation of likenesses, videos, and presentations produced by ground-based platforms, including handheld or clandestine photography taken by or on behalf of human intelligence collection organizations or available as open-source information, into the National System for Geospatial Intelligence."

"The authority provided by this paragraph does not include authority for the National Geospatial-Intelligence Agency to manage tasking of handheld or clandestine photography taken by or on behalf of human intelligence collection organizations."

Any one or a combination of the three elements, and/or the data used to create them, may be considered GEOINT. GEOINT data is described in Chapter Two.

The graphic below shows an example of each of the three GEOINT elements and the effects of combining all of them into a single product.

- The first frame in the graphic shows **Imagery**, which looks similar to a photograph.
- The second frame shows the same image with notational **Imagery Intelligence**, which refers to the analysis of the image or the information used to develop the analysis. For example, if analysis of the image indicated that the buildings shown are part of a factory used to make a particular type of weapon, that information would be considered imagery intelligence and noted on the image, as illustrated by the white callout boxes.
- The third frame depicts a map with **Geospatial Information,** which provides details— such as roads, transporation networks, location and shape of buildings, and elevation data.



NGA, Analytic Production & Design Center (ATC) Imagery Copyright 2017, DigitalGlobe

The large frame at the bottom is a comprehensive **GEOINT** product that combines all three components in a more informative and useful form to satisfy specific requirements/Essential Elements of Information (EEI)/Requests for Information (RFI) better than any of the individual components can when used separately.

Chapters Two and Three provide other examples of imagery, imagery intelligence, and geospatial information and related products.

Approved for public release, 18-142

Although the legal definition of GEOINT refers only to the **exploitation and analysis** of imagery and geospatial information—which includes processing and analyzing GEOINT data and the resulting products—there are many key areas that enable and are integral to the GEOINT function but are not part of the legal definition. These include training, architecture, data collection, technology, research and development, storage, and dissemination of GEOINT.

GEOINT DEFINITION: UPDATES AND AMPLIFICATION

Changes to the definition of GEOINT are not valid unless they are issued in U.S. Public Law, and amplifications of the definition are not valid unless they are issued or approved by the DNI or the Director of NGA.

Several documents provide amplifications to the 2005 Title 10 legal definition of GEOINT, in accordance with the guidelines stated above, but do not amend the definition provided in U.S. Code:

- The DNI issued a memo on 5 July 2005 that addressed details of what GEOINT collection activities and exploitation and analysis encompass as well as some specifics on what they do not include.
- The DNI issued a memo on 17 October 2005 that provided a detailed description of what "imagery" encompasses, including the capabilities formerly known as imagery-derived Measurement and Signatures Intelligence (MASINT) and Advanced Geospatial Intelligence (AGI).

Language from the unclassified documents, as well as the corresponding language in DoD Directive 5105.60, is provided in Appendix B.

CHAPTER TWO – DATA

This chapter describes the major categories and sources of data for all three elements of GEOINT: Imagery, Imagery Intelligence, and Geospatial Information.

1. IMAGERY

This type of GEOINT Data is collected by a system of sensors and platforms. Sensors collect the data, and platforms are the vehicles or objects to which sensors are attached. The sensor or platform used depends on the type of data to be collected, the conditions in which it is collected, and the purpose for which it will be used. The range of platforms and sensors are described below.

PLATFORMS: This section addresses satellite, aircraft, ground-based, and sea-based platforms. Aircraft, drones, aerostats, balloons, and dirigibles are referred to as *airborne* platforms. Airborne, ground-based, and sea-based platforms may be manned or unmanned/unattended.

Satellites – Imagery data is collected from space by two satellite sources: Government-owned satellites and private industry-owned satellites, known as *commercial systems.* U.S. Government satellites are used for both unclassified and classified purposes. Satellites orbit at a far higher altitude than airborne platforms, enabling them to collect above any airspace, including sovereign airspace of any nation, hostile territory, and areas to which airborne platforms are denied access.

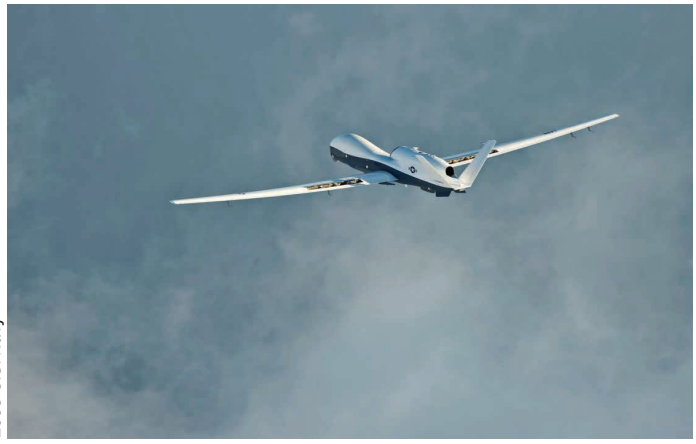
NGA

Government and Commercial

Government Systems – Sensors attached to government systems are a significant source of GEOINT data used for intelligence and national security purposes. These systems are employed when the government needs discretion in when or where it collects the data. They are used for more sensitive data collection and circumstances. Note that E.O. 12333 restricts U.S. Government systems from imaging U.S. persons.

Commercial Systems – The sensors attached to these vehicles produce unclassified data. The U.S. Government uses unclassified commercial data whenever possible, and increasingly is using commercial systems as a primary source of data. In addition, products derived from commercial system data can be more easily shared with government and military organizations outside the intelligence community, non-governmental organizations (such as non-profit relief organizations), private industry partners, foreign allies, and other foreign nations.

Approved for public release, 18-142



2008 U.S. Navy

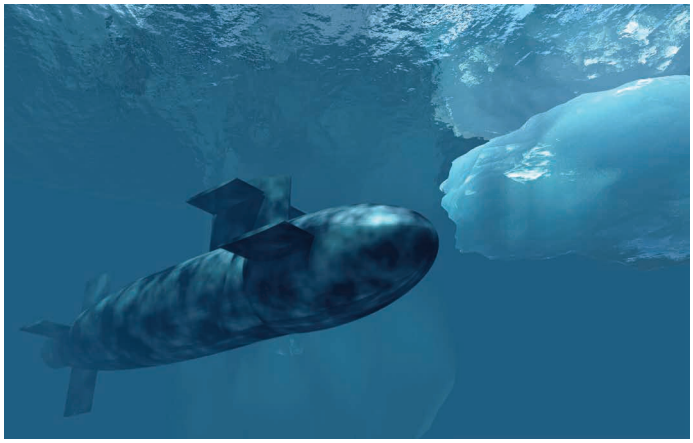
Airborne

Airborne platforms consist of manned, unmanned, fixed wing, and rotatory aircraft, as well as balloons and dirigibles. The sensors and cameras mounted on airborne platforms can provide continuous (known as *persistent*) coverage of a location or target. U.S. Government airborne platforms can often be employed more rapidly than satellites in part because military regional combatant commanders have authority over the platforms, and can re-task the platform in near real time, as required. The effectiveness of airborne GEOINT collection can be limited, however, by denied or contested airspace and adverse weather or atmospherics.

Department of Defense

Ground-based

Ground-based platforms are stationary or moving objects on or beneath the ground that have a camera or sensor attached. These platforms may be manned or unattended. The platforms can be as simple as a pole in the ground, a building, a vehicle, or a human taking photographs (known as *hand-held photography*).



Thinkstock

Sea-based/Maritime

Sea-based platforms include ships, underwater survey vessels, submarines, or buoys. They carry cameras or sensors that may be above or below the surface of the water. The platforms may be manned and unmanned.

PLATFORM CHART

This chart provides examples of common satellite, airborne, sea-based, and ground platforms, and discusses the basic advantages and disadvantages of using each.

PLATFORM TYPE	EXAMPLES	ADVANTAGES	DISADVANTAGES
Satellite – (Government)	LANDSAT GOES-R	• Global coverage/access • No cost to most users for data • Data is in Government control	• Limited collection opportunities • Limited persistent coverage of target/area • Competition for tasking priority
Satellite – (Commercial)	GeoEye-1, Worldview 1/2/3/4 Radarsat 2	• Global coverage/access • Unclassified - easily releasable • Avoids competition with higher priority IC requirements	• Competition w/ other consumers • Slower availability of products • Tasking/acquisition information generally not secure
Airborne – High Altitude (manned)	U-2/Dragonlady	• Moderate duration/persistence • Rapidly re-tasked under Theater Commander control • Wider sensor area of coverage • Can carry variety of sensors	• Less persistence than possible with UAV • Limited collection into hostile/denied airspace
Airborne – High Altitude (unmanned aerial vehicle, or *UAV*)	RQ-4/ Global Hawk MQ-4/Triton	• Very long duration; persistent surveillance • Rapidly re-tasked under Theater Commander tasking control • Moderate sensor area of coverage	• Limited collection into hostile/denied airspace
Airborne – Medium Altitude (manned)	P-3/AIP	• Moderate duration/persistence • Moderate sensor field of view/range from platform track • Rapidly re-tasked under Theater Commander tasking control • Can carry a variety of sensors	• Less persistence than possible with UAV • Very limited collection into hostile/denied airspace
Airborne – Medium Altitude Long Endurance (MALE), UAV/RPV**	MQ-1/Predator MQ-9/Reaper RQ-7/Shadow MQ-5/Hunter MQ-1C/Gray Eagle	• Long duration; persistent surveillance • Rapidly re-tasked under Theater Commander tasking control	• Narrow field of sensor view • Very limited sensor range from platform • No collection (or high risk) in hostile/denied airspace, A2AD* environment.
Ground	Buildings, Poles, Vehicles, People, Unattended Ground Sensor (UGS)	• High resolution/detail possible • Long duration availability • Less expensive than most other types of platforms • 24-7, open source coverage	• Difficult placement/access in A2AD* environment • Very limited sensor range • Authentication
Sea	Ships, Buoys, Submarines	• Underwater imagery, topography • High-resolution bathymetry	• Limited to good sea conditions • Narrow sensor swaths

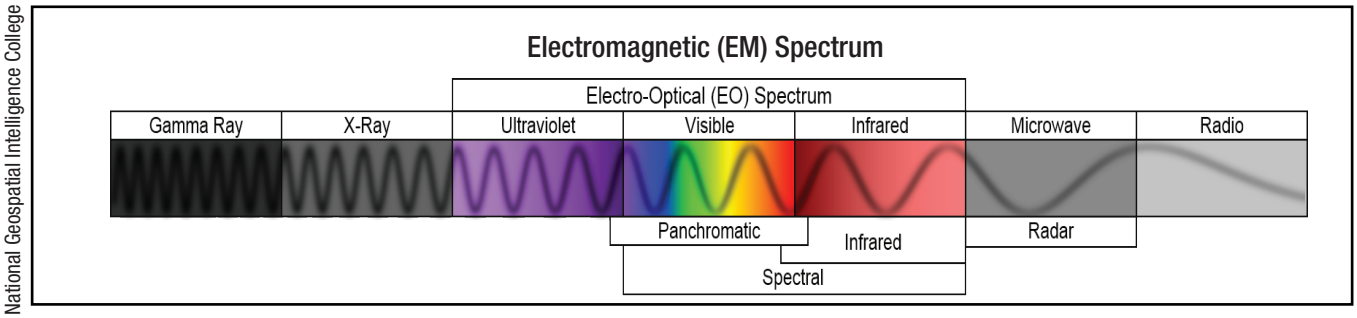
Approved for public release, 18-142



Portions of the Electromagnetic Spectrum used for Phenomenologies

SENSORS: The two primary categories of sensors are electro-optical (EO) and radio detecting and ranging (radar), and both have several types or variants, known as phenomenologies. Each phenomenology achieves different results with the data. Descriptions of sensor characteristics and phenomenologies are listed below. At the end of this chapter, we discuss how sensors are used to capture and characterize motion.

ELECTRO-OPTICAL (EO)

EO derives data from the ultraviolet through the infrared portions of the electromagnetic (EM) spectrum. Each part of the EM spectrum provides a different representation of the object imaged, depending on the sensor phenomenology used. EO sensors are passive (with the exception of light detecting and ranging, or lidar, described below), which means they use natural EM energy sources such as the sun, naturally occurring radiation, or emitted heat. They generate data by capturing the reflected or emitted electromagnetic energy from an object. These sensors, which operate only in a passive or "receive" mode,* do not emit energy. This factor diminishes the adversary's ability to detect whether they are being imaged. The effectiveness of electro-optical sensors can be degraded or denied by adverse weather, light conditions, and atmospherics.

*Except Lidar

EO PHENOMENOLOGIES

PANCHROMATIC IMAGING (PAN)

Copyright 2008, DigitalGlobe

PAN uses the visible part of the EM spectrum, along with a portion of IR spectrum, and produces an image similar to a black and white aerial photograph. The images can provide a very detailed and accurate likeness of an area or object, and can show shadows and other distinguishing features that help identify characteristics of an object or environment.

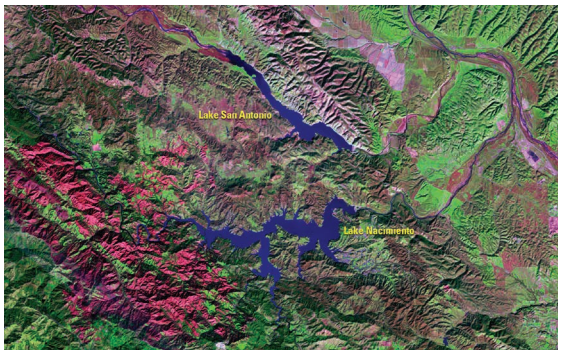
INFRARED (IR)

USGS

IR uses the infrared part of the EM spectrum to detect heat and radiance/reflection, and displays that information in a gray-scale image.

Thermal Infrared (TIR) – TIR is similar to IR, but it uses different wavelengths of the infrared spectrum to indicate the temperature of objects or radiated/reflected heat. The shape and size of the object or environment emitting energy (heat) is shown as a different shade than the rest of the image. Cooler objects appear darker, warmer objects appear lighter, and hot objects appear bright white.

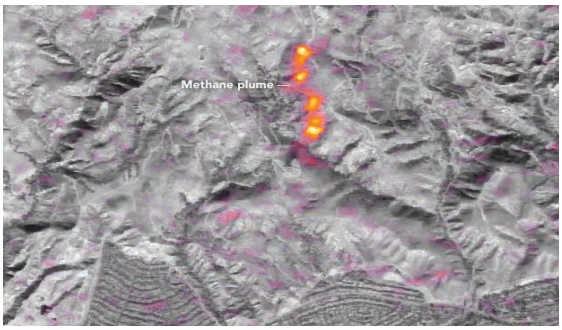
MULTISPECTRAL IMAGING (MSI)



USGS

MSI provides a color image by using tens of additional bands of the visible and infrared portions of the spectrum. It also provides more detail to images, showing characteristics that are not otherwise visible. The bands can be combined in various ways to highlight different manmade or natural features.

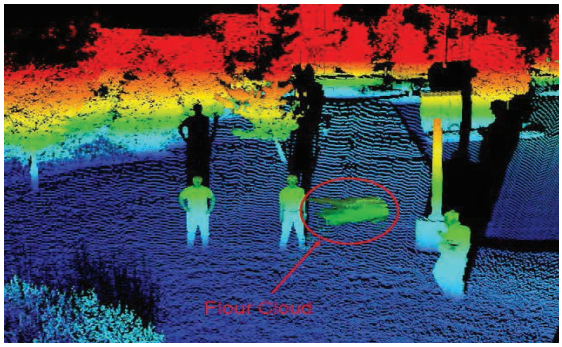
HYPERSPECTRAL IMAGING (HSI)



NASA

HSI is similar to MSI but uses hundreds, rather than tens, of bands of the visible and infrared portions of the EM spectrum. These extra bands can provide greater fidelity and characteristics of an object than MSI. For example, HSI allows users to detect materials by their unique spectral signature.

LIGHT DETECTION AND RANGING (LIDAR)



NGA Office of Corporate Communications

Lidar uses laser pulses in the visible and infrared portions of the EM spectrum. The sensor emits a pulse of laser light toward an object, which reflects back some of the energy to the sensor. The time it takes for the energy to return provides information that helps identify many characteristics of an object and the environment, including distances and heights. For example, shorter roundtrips indicate higher elevations and longer roundtrips indicate lower elevations. The process can be used to develop three-dimensional models of an object, such as a building.

Approved for public release, 18-142

OVERHEAD PERSISTENT INFRARED (OPIR)

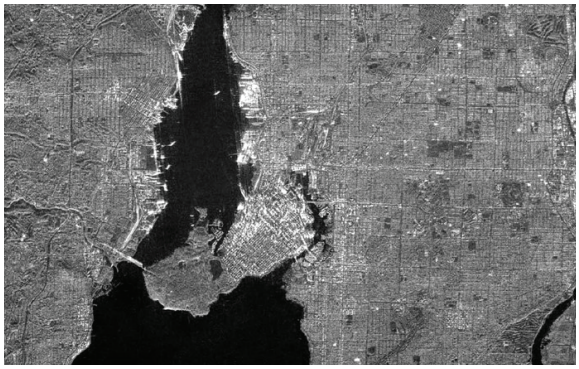
OPIR combines several EO sensor phenomenologies described above to create a unique collection capability that detects energy radiation from tactical and strategic targets and allows continuous (known as persistent) coverage of a mission area. OPIR can detect energy radiance in the visible and near infrared, short-wave infrared and mid-wave infrared parts of the spectrum to characterize energy as an event or process it as a scene.

RADAR

Radars are active sensors that emit manmade electromagnetic energy to illuminate the environment or object they are imaging, and then use the characteristics of the response to create an image. These sensors use reflected radar energy to illuminate objects in day or night and in almost any weather conditions. A radar image is non-literal, which means it does not appear as a photo that shows an exact likeness of an object or environment. It is similar to an X-ray of an area or object, with the ability to detect characteristics that a literal picture would not show. An important feature is that it can be used for poor light and weather conditions in which EO technologies are less effective.

RADAR PHENOMENOLOGIES

SYNTHETIC APERTURE RADAR (SAR)



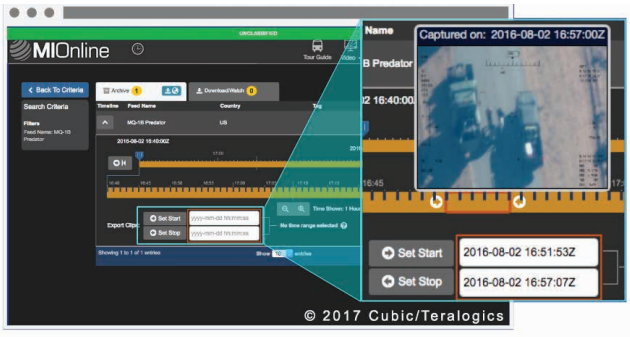
Copyright 2008, Macdonald, Dettwiler & Associates

SAR illuminates objects with pulses of microwave energy. It applies signal processing to a series of many pulses to produce imagery.

Interferometric SAR (IFSAR) – IFSAR uses a SAR sensor to observe a location from two separate positions. This method generates elevation data of the Earth's surface.

MOTION GEOINT

Both EO and radar sensors can create or capture motion by collecting multiple frames over a short period of time. This activity is known as Motion GEOINT. The most common types of Motion GEOINT include the following:



Search

Full Motion Video (FMV) – FMV uses many frames per second to create a near-real-time video capability, which may be displayed as visible or IR and may be recorded by digital or analog means. This near-real time capability allows observation of rapidly developing events and is a valuable tool for ongoing operations. It also provides continuous observation of an object, such as a person or vehicle, to analyze its patterns over long periods.

Moving Target Indicator (MTI) – This predominantly radar capability shows only those objects that are in motion and provides information on the speed and direction that objects are moving. Some EO sensors can detect motion in a small area but generally are not considered an MTI capability.

Wide Area Motion Imagery (WAMI) – A set of motion imagery sensors with a wide field of view (FOV) diameter of up to 8 km, which provides continuous surveillance of a broad area.

FMV, MTI, and WAMI are primary sources of collection that allow persistent coverage of a target or area. All three enable forensic backtracking of kinetic events, network analysis, pattern of life (PoL) studies and security monitoring. Motion imagery is also a key enabler of Activity Based Intelligence, as discussed in Chapter Three.

SENSOR & PHENOMENOLOGY CHART

SENSOR/PHENOMENOLOGY	ACRONYM/ SHORT FORM	CHARACTERISTICS	USED FOR (EXAMPLES)
ELECTRO-OPTICAL SENSOR	**EO**	**Typically a passive sensor, uses natural energy sources, ultraviolet through infrared portions of EM spectrum**	**For detailed, literal, photo-like picture of a scene and the objects within it.**
PANCHROMATIC	PAN	Uses the visible section of the spectrum to create black and white (grayscale) images.	Provides a literal picture of a scene, area, and/ or objects. Used in daytime, good weather conditions.
INFRARED	IR	Uses the infrared portion of the spectrum to detect heat/ radiance.	Detects presence of living entities and active vehicles and equipment in day or night. May be limited by bad weather/light conditions, smoke.
• Thermal Infrared	TIR	Uses infrared portions of the spectrum to indicate temperature level of heat/radiance.	Determines operational status of equipment, factories, and nuclear facilities. Penetrate smoke, track activities at airfields, ports, etc.
MULTISPECTRAL IMAGING	MSI	Uses tens of visible ***and*** infrared bands to provide a color image with more detail.	Sees beneath the water; detects camouflage, vegetation density and cover type, mineral, soils, and material analysis; illuminates shadowed material.
HYPERSPECTRAL IMAGING	HSI	Uses hundreds of visible ***and*** infrared bands to provide a greater detail and additional characteristics.	Same as multispectral but with greater levels of detail.
LIGHT DETECTION & RANGING	Lidar	Uses laser pulses in the visible and infrared sections of spectrum.	See objects beneath vegetation canopy, battlefield visualization
OVERHEAD PERSISTENT INFRARED	OPIR	Uses visible and near infrared bands. Characterizes energy as an event, processes as a scene.	Provides persistent coverage. Detects missile launches, wildfires, hostilities, volcanos, and identifies weapons.
RADAR SENSOR	**Radar**	**Active sensor, emits manmade energy sources, uses microwave and radio wave portions of EM Spectrum.**	**Unlike EO, can be used in most weather, day or night.**
SYNTHETIC APERTURE RADAR	SAR	Illuminates objects with microwave energy pulses. Applies signal processing to a series of pulses to produce a single image.	Penetrates foliage, material, and ground (with limitations), detects barriers and overhead power lines. Used in most weather, light conditions. Creates a black & white (grayscale) image.
• Interferometric SAR	IFSAR	Uses SAR sensor to observe from two separate positions to generate elevation data of the Earth's surface.	Identifies elevation data.

Approved for public release, 18-142

2. IMAGERY INTELLIGENCE

Imagery intelligence data is produced during analysis of the imagery and geospatial data. The data may be derived from analytic expertise, classified data, unclassified information, analysis techniques, or any combination of those sources. For example, an analyst may determine that two objects on an image are foreign aircraft from a specific country based on expert knowledge of foreign aircraft. The analyst may then use unclassified publications to determine the exact nomenclature of the aircraft and review classified intelligence reporting to assess whether this is the first appearance of such aircraft in this location and if the arrival of the aircraft is related to military or political activity in the area. The analyst might also employ analysis techniques to determine other information about the aircraft, location, or arrival details.

3. GEOSPATIAL INFORMATION

Geospatial Information is derived from data collected through many different sources including: platforms and sensors used for imagery data; subsurface sensors, such as sonar (sound navigation and ranging) attached to water-based platforms including ships, submarines, and buoys; ground sensors, such as seismic, attached to land-based platforms such as vehicles, stationary poles, or humans; and open source information, such as population.

Geospatial Information can be separated into seven major categories, as described below.

Aeronautical: Safety of Navigation information such as vertical obstructions, no-fly zones, flight routes, approach procedures, airfield infrastructure and layout, and aeronautical charts.

Maritime: Safety of Navigation information such as shipping routes, underwater obstructions, sailing restrictions, port infrastructure and layout, approach procedures, and nautical charts.

Topographic: Safety of Navigation information such as trafficability and obstacles to movement, and other ground/surface feature-related information including infrastructure (roads, power grids), man-made features, population data, vegetation, and hydrography. Topography may also include connectivity of network elements within a geospatial database that allow for ground-based routing, navigation, and hydrology flow.

Elevation: Information about the height of objects on or in relation to the Earth. Elevation data includes heights of objects above the surface of the Earth (spaceborne and airborne), on the surface of the Earth (buildings and physical relief), and below the surface (bathymetry and underground facilities).

Human Geography: A social science discipline based on analyzing the interconnections between people and places, including patterns of human activities, in the context of their environment. It also seeks to explain how actions taken in one place/population can impact another place/population. Human Geography includes sub-disciplines such as: population geography, political geography, cultural geography, and religious/ethnic geography. It may include both classified and unclassified information.

Geographic Names and Boundaries: Names and boundaries of cities, towns, provinces, regions, states, and countries. Identification of major landmarks, facilities, and buildings.

Geodetic: Magnetic and gravimetric data (which have an impact on geo-positional systems), navigation tools, surveying, and systems of map grids and coordinate systems.

NOTE: The combination of these seven categories and a category called “Controlled Imagery,” may be referred to as “Foundation GEOINT.”

CHAPTER THREE – PRODUCTS

GEOINT products enable the visualization and geo-location of intelligence gathered from intelligence disciplines, known as INTs, as well as information from non-intelligence sources. Products range from simple to advanced, depending on the type and amount of information used, level of analytic complexity, and use of different processing techniques. Sometimes, a simple product, such as a map or image with annotations, may be all that a user needs. In some cases, a more sophisticated product is required in order to provide the type of information or level of detail needed to accomplish a mission or answer a question. In the first section, we will describe GEOINT products, from the most basic form through the most advanced. The second section "Product Examples & Applications" will show a variety of products and provide examples of how they are used for different missions and purposes.

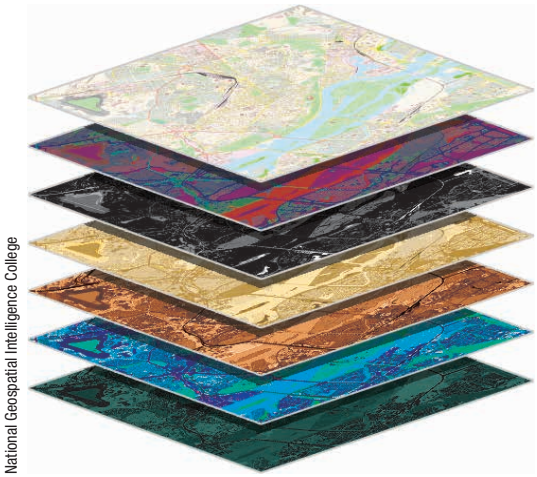
BASE PRODUCTS

The foundation (first layer) of a GEOINT product may consist of any one or combination of the GEOINT components described in the Section "What is GEOINT?" This foundation usually* is a map or image of a specific location and shows visible terrain, objects, and other features in that location. GEOINT images and maps are unique because they can display highly accurate geo-coordinates of the location, as well as additional information on objects or features depicted.

*As noted earlier, data is used to create a product. But in some cases, the processed data itself is the product. For example, certain forms of data are used to create a product called a Digital Point Positioning Database, which is used to derive digital information that is fed directly into weapons systems to ensure accuracy. However, to simplify the explanation of GEOINT products, this section focuses on describing how products are created using maps and images as a foundation.

LAYERING

Different types of information can be layered onto the foundation to provide more detail and context. However, the information must be geospatially referenced, meaning that it is shown in the precise location, within the exact associated grid coordinates, that it appears on the image or map. There is a wide variety of information that can be added to customize the image for its intended purpose, as described below.



National Geospatial Intelligence College

GEOSPATIAL LAYERS: Comprise geospatial information including boundaries, infrastructure (such as sewer lines, power grids), elevation data, geodetic data, human geography data (population, cultural, political/religious geography), safety of navigation data, and identification of key facilities and natural or manmade features.

MISSION LAYERS: Provide general information relevant to the purpose and area for which the product is being used. The information may include weather conditions and climate, logistics data, locations of friendly forces, routes and alternatives, characteristics of the local terrain, population and government information, and other data obtained through commonly used, unclassified sources.

INTELLIGENCE LAYERS: Customize products for a specific mission or purpose and consist of information derived from various intelligence sources, or a combination of those sources. Examples include locations of friendly and enemy forces, presence of chemical or biological hazards, weapons facilities, routes and alternatives, and potential targets. GEOINT serves as a base for the depiction of data from other intelligence disciplines (INTs), each of which is described below. (These are user-friendly descriptions approved by the agencies responsible for each INT. They are not the official definitions in law.)

- Human Intelligence (HUMINT) – Intelligence obtained through clandestine or overt HUMINT activities, or operations and activities utilizing human sources or other human assets.

- Imagery Intelligence (IMINT) – The technical, geographic, and intelligence information derived through the interpretation or analysis of imagery and collateral materials.

- Signals Intelligence (SIGINT) – A form of technical intelligence derived from the exploitation of foreign electronic emissions. SIGINT can be in the form of the actual information content of a signal or in the form of its temporal and spectral characteristics, called signal operating parameters. SIGINT includes both the raw data and the analysis product of that data. This category of intelligence includes all Communications Intelligence, Electronic Intelligence, and Foreign Instrumentation Signals Intelligence.

- Measurement and Signature Intelligence (MASINT) – Scientific and technical intelligence information obtained by quantitative and qualitative analysis of data. MASINT, which is derived from specific technical sensors, identifies distinctive features associated with the source, emitter, or sender. It can measure physical characteristics of targets and events of interest to determine composition, location, and/or performance.

- Open Source Intelligence (OSINT) – Intelligence produced from publicly available information that is collected, exploited, and disseminated in a timely manner to an appropriate audience for the purpose of addressing a specific intelligence requirement.

Conflation or adding one or more of these layers to a GEOINT product is considered *Multi-INT*, which means that input from at least one additional INT was used to provide as much context as possible to a GEOINT product depicting a specific object, area, or activity. Multi-INT GEOINT should not be confused with all-source intelligence, in which data and products from all INTs are used to provide a comprehensive strategic assessment. Even the most comprehensive Multi-INT GEOINT product may only be one part of an all-source analysis subject, such as a matter spanning multiple regions, networks, or governments or an issue that involves strategic relationships and intentions.

ADVANCED ANALYTICS: ELEVATION, INTERACTION, AND ACTIVITY

Analysts may introduce any of the following elements to create a more dynamic, realistic, and advanced GEOINT product.

Elevation: The majority of GEOINT products use one or more of the layers described above. However, a more sophisticated product can be developed by adding elevation to create a three-dimensional (3D) model or simulation that provides a more realistic representation of an environment or object.

Time: The element of time can be used to create temporal products. These products can simulate factors such as speed, tides, wind direction, and changing daylight to help the analyst determine how each factor will affect a mission or event.

Motion: Location, elevation and time can be combined to create a virtual, interactive scene that allows users to familiarize or train in a simulated environment before operating in a real situation. Such simulations also allow analysts to experience different perspectives from which to analyze objects and scenarios.

Activity: Most GEOINT analysis and products focus on providing as much information as possible about a specific object or area. However, activity-based analysis examines human, vehicular, and other activity related to that object or area, which can lead to different areas and show correlations between areas, people, and objects. This method allows for a more complex level of analysis. Three processes that contribute to activity-based analysis are listed below.

- **Object-Based Production (OBP):** OBP is the standardized IC process in which observations from sensors are captured, structured, stored, and shared. The process also brings together information from all available sources of intelligence—and from systems of different security levels—related to an object. Thus, the most comprehensive and up-to-date information is available to everyone at the same time, and analysts from any location or organization can rapidly access the data. Examples of objects include natural features, people, vehicles, buildings, and events.

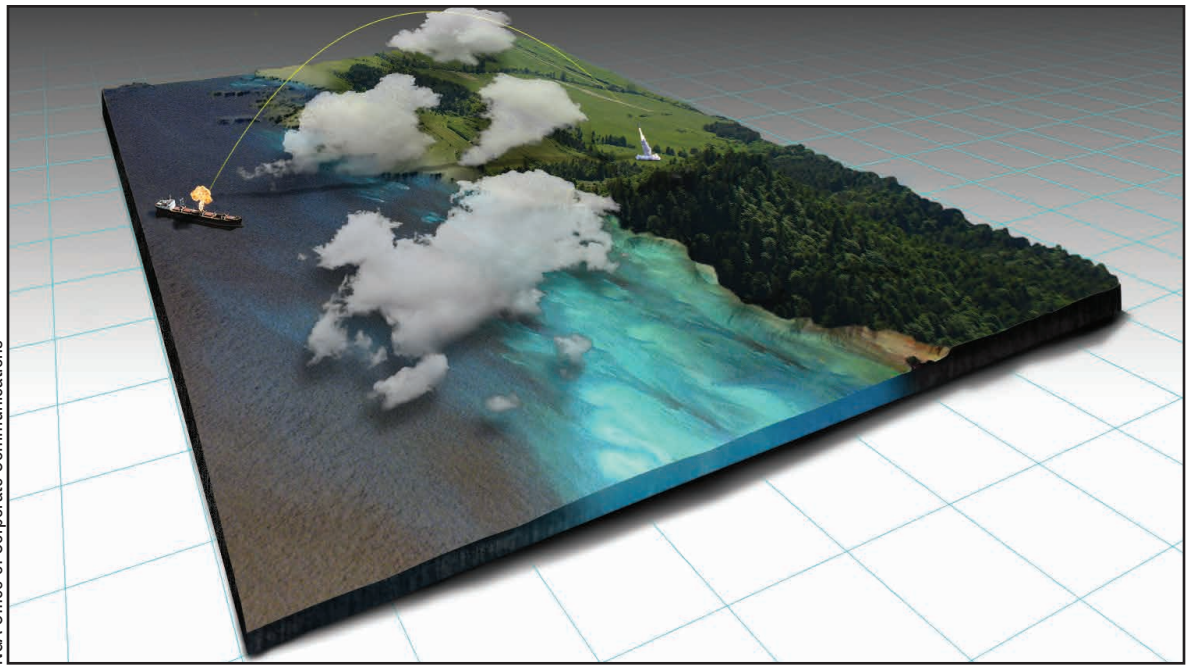
Approved for public release, 18-142

- **Structured Observation Management (SOM):** SOM is the method in which GEOINT observations from satellites and sensors and other sources are captured, structured, stored, and shared in a standardized format compatible with the OBP format. This ensures that GEOINT information can be integrated into the IC's OBP process.

- **Activity-Based Intelligence (ABI):** ABI is a methodology that incorporates the OBP information into a process that can detect when the object changes or activities related to an object occur, and then provide an electronic "alert" to analysts interested in that object. By examining this new information about the object, analysts can discover relationships with other objects or locations and detect patterns of activity and behavior.

PRODUCT EXAMPLES AND APPLICATIONS

A wide variety of products can be created to satisfy specific mission requirements by using different types of data, data processing, or analysis. Most products provide a common, accurately geo-located visualization of a scene or environment to enable planning and collaboration among different organizations. In this section, we will provide examples of products grouped in categories that are related to the overall missions and purposes for which the products are used: Mission/Event Preparation, Assessments, and Detection.



NGA Office of Corporate Communications

3D Simulation that incorporates elevation, time, and motion.

Mission/Event Preparation – Used to prepare for a mission, operation, or major event. These products focus on familiarization with the area, including identification of key landmarks and existing or potential hazards. They usually are map or imagery products that facilitate safety of navigation by identifying elements such as buildings, routes, water depth, terrain features, obstacles, and threats. The products assist with activities such as route planning and security preparations.

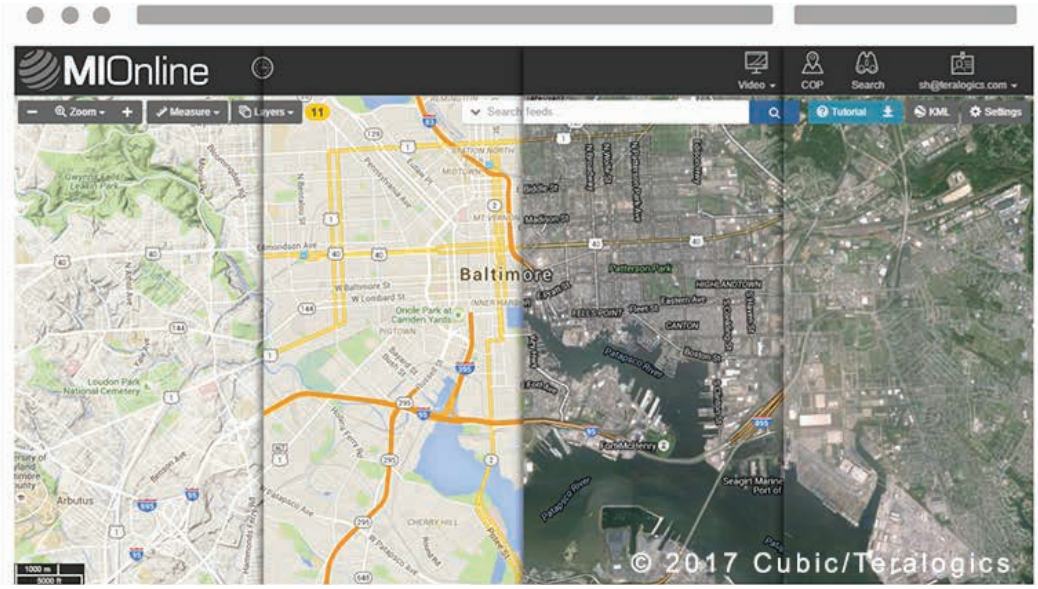
Assessment – Provide analysis for what is shown in an image or on a map, and provide information on the "who, what, when, where, how, and why," usually in the context of the purpose or mission for which it has been developed. Such products may be a simple image of a facility and parking lot, with notations that indicate the type of facility, information on how many cars are parked there now compared with the usual volume, and an assessment of how many people may be in the facility and what types of activities they may be conducting. A more complex product may show a hazardous material leak, with notations on potential effects over time using variable factors such as wind speed and tides.

Detection – Designed to find natural and manmade materials that are not visible or easily identifiable to the human eye. A variety of EO or radar sensor phenomenologies and specialized data processing techniques are used to develop detection products. These products may be used for many purposes, such as to "see" beneath foliage and camouflage or identify heat and other emissions.

PRODUCT EXAMPLES AND APPLICATIONS

Below are examples of products for each of the categories described above.

MISSION/EVENT PREPARATION



Map Overlays

Products such as map overlays and digital nautical charts are used to analyze locations for potential security threats and emergency operations, well in advance of a major event or VIP visit. Examples include the beach volleyball venue for the 2016 Olympics in Rio, Brazil, and the stadium area for the Super Bowl in Jacksonville, Florida.

ASSESSMENTS

2015 DigitalGlobe NextView License

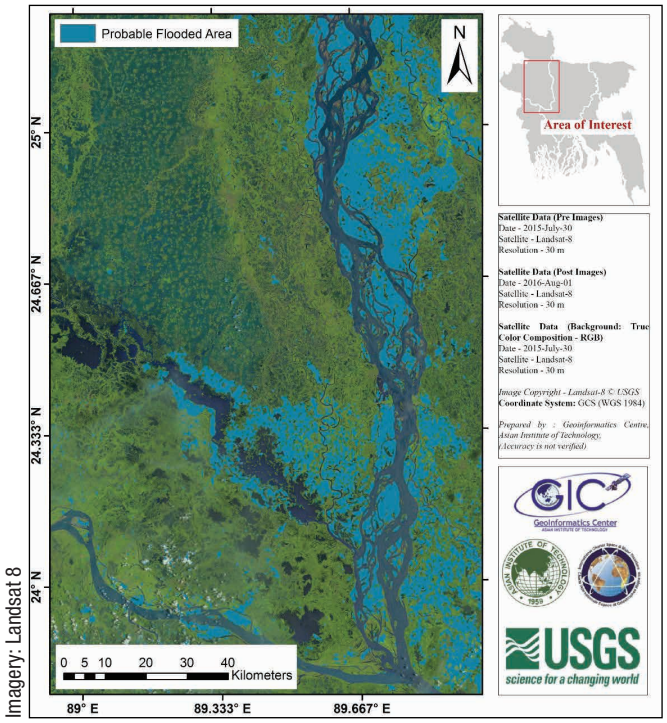
This example is from the 2015 earthquake in Nepal. On the left is an image from before the earthquake and on the right is an image after the earthquake. Analysts compared the two images to identify damaged structures, accessible roadways, and internally displaced persons. The results of that analysis were sent to the U.S. State Department, which provided the information to first responders and NGOs assisting in the recovery effort.

2015 DigitalGlobe NextView License

This image shows two separate camps for persons displaced after the earthquake. Analysts estimate the number of displaced persons in this area by counting the number and size of the tents. This information allows the State Department to determine the appropriate amount of food, water, clothing, and other supplies or support the affected people may need.

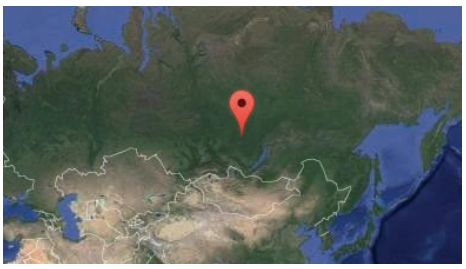
Flood inundation along the Brahmaputra River in Bangladesh

Over 3.2 Million people were affected by flooding in Bangladesh with 250,000 houses fully or partially damaged and 25,000 people displaced.

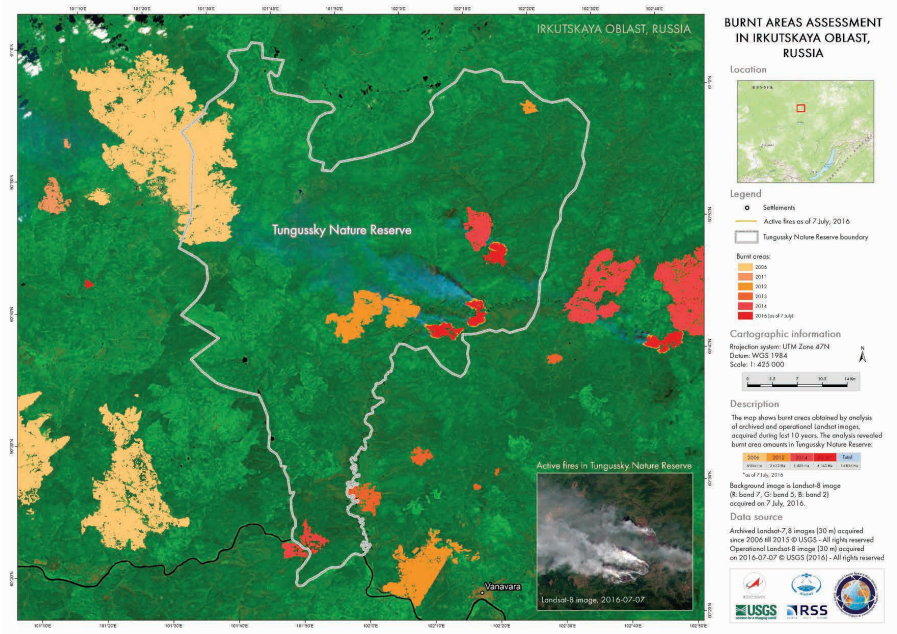


A total of 38 people have drowned since flooding began on July 25, 2016.

Burnt areas assessment in Irkutskaya Oblast, Russia



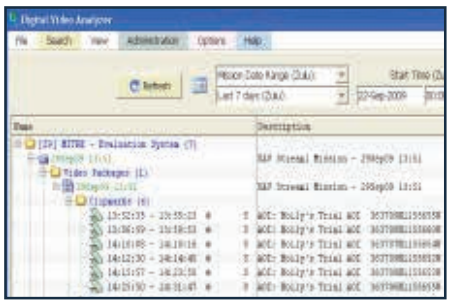
The Siberian Wildfires were triggered by lightning in late June and burned around 3,000 hectares.

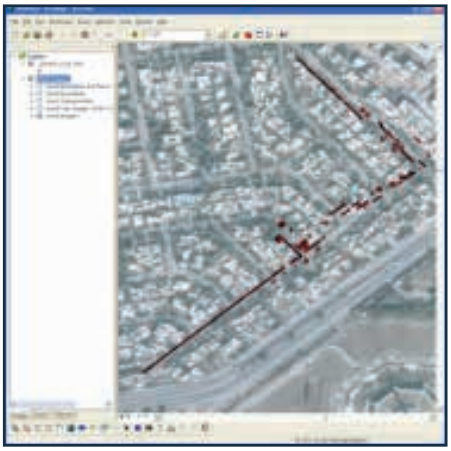


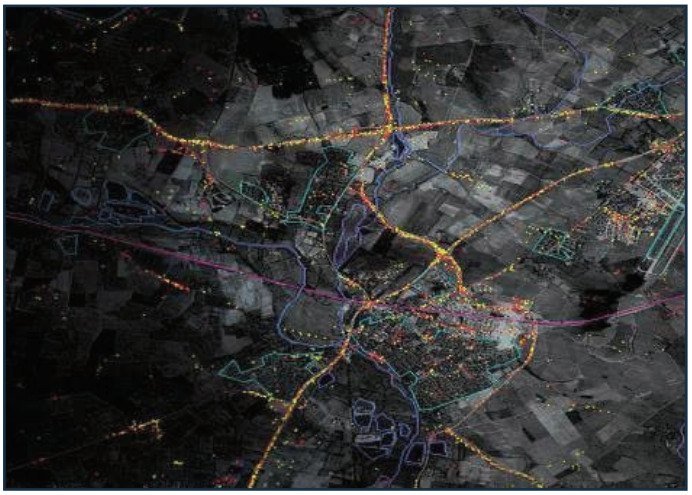
The fires were located in remote areas and did not pose a threat to inhabited areas at the time.

Approved for public release, 18-142

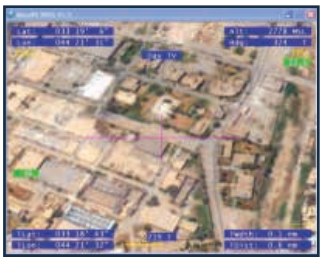
DETECTION

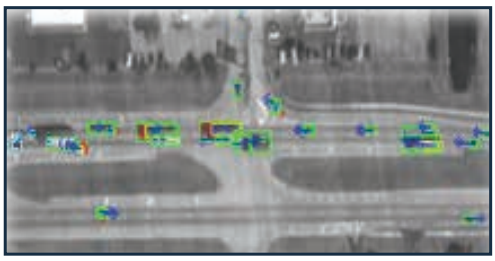






JSTARS image (DoD)





This Activity Based Intelligence (ABI) product illustrates how information extracted from large-scale data (also called *big data*) can be used to detect activity, patterns, networks, and anomalies. The NSG increasingly is using automation, which serves as a framework for advancing GEOINT to its future state.

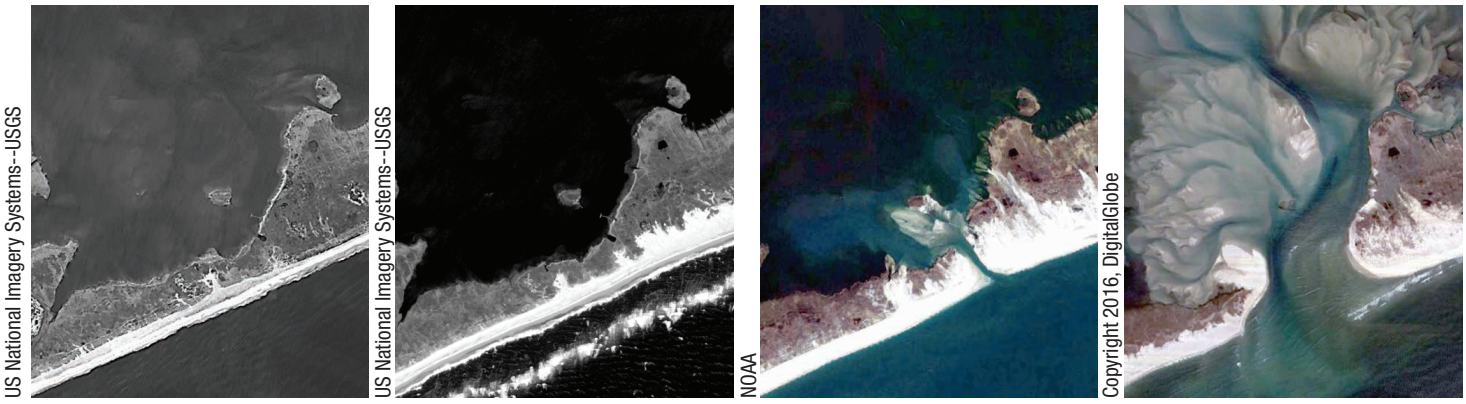
Spratly Islands, South China Sea

Construction of man-made island reefs with pumped sand is documented by DigitalGlobe's satellites over a period of 25 months. Change detection using EO sensor.



Fire Island National Seashore, New York
Five Global Fiducial Program (GFP) time series images showing changes that occurred at Fire Island National Seashore, New York during the 17+ year period from March 1999 to May 2016. The GFP uses imagery from multiple sources to document dynamic Earth processes and change.

PRODUCT STORAGE, DISSEMINATION, AND ACCESS

GEOINT data and products are accessed by or delivered to producers and users via storage and dissemination systems. The system used may depend on the classification level of the data or products, type of sensor platform used to obtain the data, level and type of organization that produced the products, or whether hardcopy or electronic versions are needed. There are numerous national, military, and commercial GEOINT libraries for GEOINT data and products. However, the Director of NGA, as the GFM, established the NSG Consolidated Library (NCL) for long-term, large-volume storage of GEOINT data.

Traditionally, products were "pushed" to users via a variety of dissemination systems. However, with the advancement of technology, users may readily access many repositories themselves and can select and independently "pull" the specific data or products they need from storage systems.

Approved for public release, 18-142

CHAPTER FOUR – TRADECRAFT

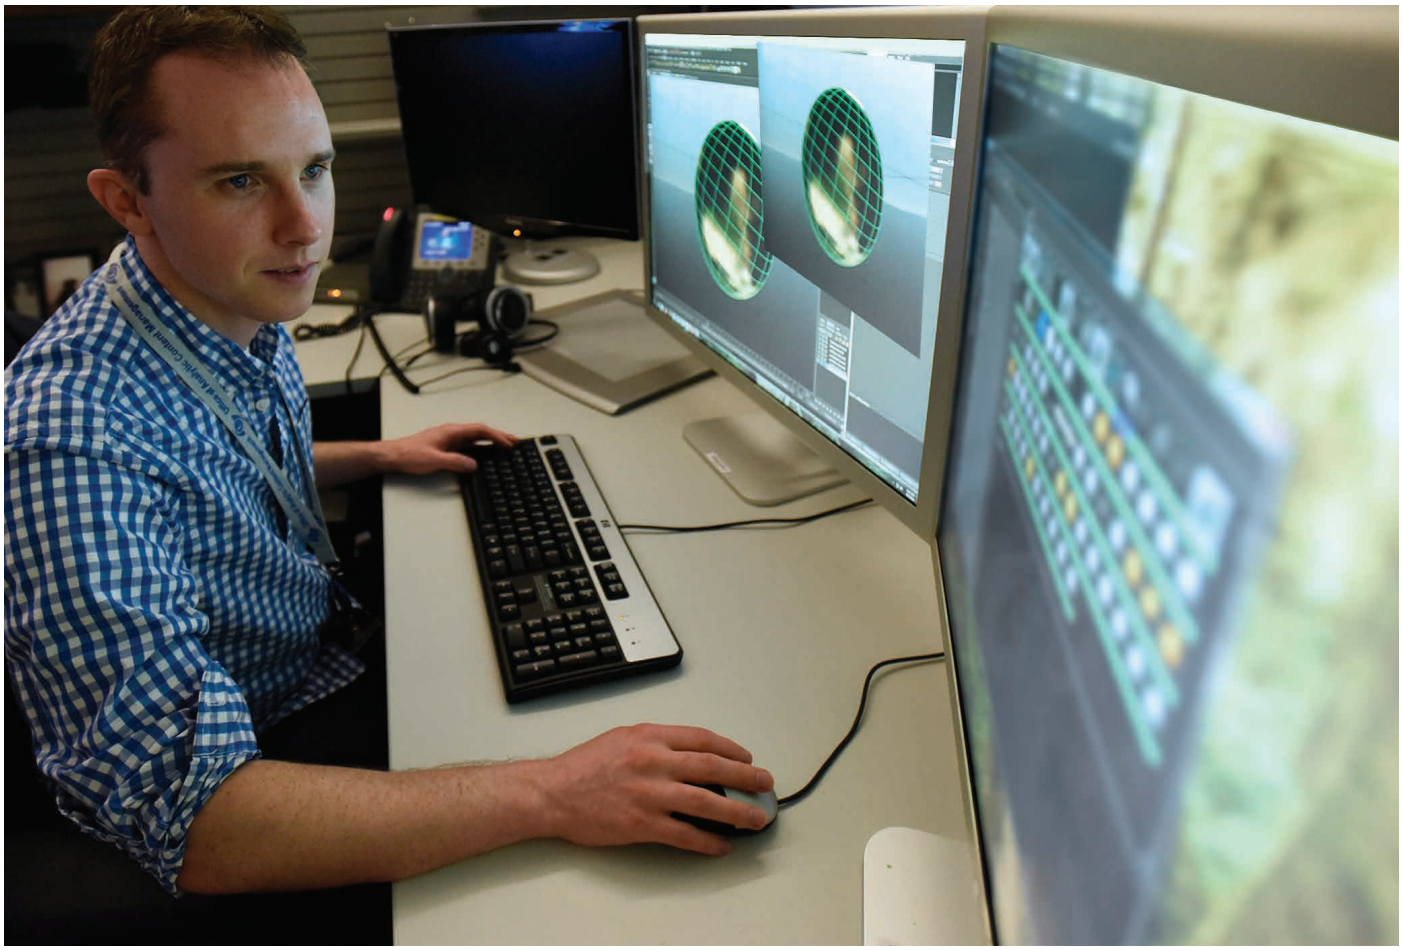


Photo by Erica Knight, NGA Office of Corporate Communications

GEOINT is a specialized field of practice, with a U.S. Government professional certification program that is mandatory for most Agencies and Services. The GEOINT discipline encompasses all activities involved in the planning, collection, processing, analysis, exploitation, and dissemination of spatial information in order to gain intelligence about the national security or operational environment, visually depict this knowledge, and fuse the acquired knowledge with other information through analysis and visualization processes.

The GEOINT discipline is much more than systems, processes, and products; it includes highly skilled, educated professionals and the many specialized tradecraft areas in which they work. GEOINT Tradecraft is the application of skills, technology, techniques, leadership, continuing education, mentoring, special experiences, and knowledge of GEOINT in one or more occupational specialties, which are described below.

GEOINT PROFESSIONAL TRADECRAFT AREAS

NGA Photos

- **Aeronautical Analysis –** The analysis and exploitation of worldwide aeronautical data and other sources in support of safety of navigation and national security goals, concerns, requirements, and strategies.
- **Applied Sciences –** The analysis of the Earth's gravity and magnetic fields, geophysical structure, material properties, and dynamics for geospatial intelligence and DoD applications. Professionals in the applied sciences provide in-depth technical expertise on Geodetic and geophysical issues and satellite issues.
- **Cartography –** The art and science of making maps and charts.
- **GEOINT Collection –** The collaboration with customers and source providers to develop comprehensive GEOINT, multi-source strategies to address intelligence problems. Professionals in this field create tasking and dissemination requirements, adjudicate requirements, analyze and investigate collection performance, assess collection opportunities, assess and report on the end-to-end GEOINT system performance data, advise customers, and satisfy essential elements of information (EEI) requirements.
- **Geospatial Analysis –** The science of extracting meaning from geospatial data and using geographic information systems to uncover and investigate relationships and patterns in all forms of geospatial data to address intelligence or military issues.
- **Geospatial Data Management –** The management of the development, approval, and population of geospatial data within a feature database to ensure that it can be used to satisfy customer requirements. This requires knowledge of the wide range of products and a solid understanding of the capabilities of various systems used to support the extraction, analysis, and finishing of in-house, co-production, commodity, and contract data.

Approved for public release, 18-142

- **Human Geography –** The science of understanding, representing, and forecasting activities of individuals, groups, organizations, and social networks with a geo-temporal context. Human Geography professionals gather, assess, and evaluate source materials and ensure its quality and suitability to build foundational data and apply knowledge and expertise in physical, socio-cultural, and political aspects of countries, regions, and urban areas to support national security goals, concerns, and strategies. This data is analyzed to characterize events, discover relationships and trends, infer conclusions, and predict behaviors.

- **Imagery Analysis –** The science of converting information, extracted from imagery, into intelligence about activities, issues, objects, installations, and/or areas of interest.

- **Imagery Science –** The generation, collection, duplication, analysis, modification, and visualization of images. It includes the use of advanced techniques to identify objects that cannot be detected by the human eye. Imagery science is used to develop algorithms, evaluate tools, and create customized methodologies and products to address a variety of geospatial intelligence problems. Imagery scientists typically specialize in precision mensuration, radar, spectral, infrared, and other specialized collection systems.

- **Maritime Analysis –** The acquisition, analysis, compilation, and dissemination of maritime safety of navigation information to populate and update nautical databases to support the Digital Nautical Chart, hardcopy charts, digital publications, and Electronic Chart Display and Information Systems. Marine Analysts generate datasets, promulgate worldwide navigational warnings, and respond to queries from foreign hydrographic offices and the users of our products and services.

Each GEOINT tradecraft area has specific duties within it. Civilian and military GEOINT professionals often perform similar functions but have different job titles. The chart below shows the GEOINT civilian job titles/categories and the corresponding military designations for each tradecraft area.

Evolving Work Role - Data Scientist. This work role will soon become a primary GEOINT tradecraft role. A community-coordinated definition will be provided in the next Publication 1.0 update.

GEOINT TRADECRAFT WORK ROLE/DESIGNATION CHART

TRADECRAFT AREA	GOVERNMENT CIVILIAN DESIGNATION	MILITARY DESIGNATION
Aeronautical Analysis	GEOINT Analyst (Aeronautical Intelligence)	Geospatial Engineer (Army–12Y) Geospatial Engineering Technician (Army–125D) Air Traffic Control Terps Specialist (Air Force–1C1X1) Geographic Intelligence Specialist (Marine Corps–0261)
Applied Sciences	GEOINT Analyst (Geodetic Earth Science) GEOINT Analyst (Geodetic Survey) GEOINT Analyst (Geodetic Orbit Sciences) GEOINT Analyst (Bathymetry) GEOINT Analyst (Oceanography) GEOINT Analyst (Meteorology) GEOINT Analyst (Hydrography) GEOINT Analyst (Precise Time/Astrometry)	Technical Applications Specialist (Air Force–9S100) Technical Engineer (Army–12T) Geospatial Engineering Technician (Army–125D) Diver (Army–12D) Aerographer's Mate (Navy Officer–1800) Geospatial Engineer (Army–12Y)
Cartography	GEOINT Analyst (Cartography) GEOINT Analyst (Photogrammetric Cartography)	Geospatial Engineer (Army–12Y) Geospatial Engineering Technician (Army–125D) Geographic Intelligence Specialist (Marine Corps–0261)
GEOINT Collection	GEOINT Analyst (Foundation Strategies) GEOINT Analyst (Open Source Research) GEOINT Analyst (Persistent Operations) GEOINT Analyst (Source Strategies) GEOINT Analyst (Throughput Strategies) GEOINT Analyst (Requirements & Integration)	Operations Intelligence Officer (Air Force–14N) Operations Intelligence Technician (Air Force–1N0) GEOINT Imagery Technician (Army–350G) GEOINT Imagery Analyst (Army–35G) GEOINT Officer (Army–35D–1D) Technical Engineer (Army–12T) Engineer Officer (Army–12A–W2) Imagery Analysis Specialist (Marine Corps–0241)
Geospatial Analysis	GEOINT Analyst (Geospatial Analysis) GEOINT Analyst (Analytical Methodologies) GEOINT Analyst (Infrared Source Analysis)	Targeteer (Air Force–1N1X1B) Technical Applications Specialist (Air Force–9S100) Geographic Intelligence Specialist (Marine Corps–0261) Geospatial Engineer (Army–12Y) Geospatial Engineering Technician (Army–125D) Engineer Officer (Army–12A-W2)
Geospatial Data Management	GEOINT Analyst (Data Stewardship) GEOINT Analyst (Database Management)	Geospatial Engineer (Army–12Y) Geospatial Engineering Technician (Army–125D) GEOINT Imagery Technician (Army–350G) GEOINT Imagery Analyst (Army–35G) GEOINT Officer (Army–35D–1D) Engineer Officer (Army–12A–W2) Geographic Intelligence Specialist (Marine Corps–0261)

CHAPTER FIVE – GEOINT COMMUNITY & GOVERNANCE

This chapter has two sections. The GEOINT Community section addresses the National System for Geospatial Intelligence (NSG), an organization comprised of IC and DoD elements, and identifies the NSG's Principal Partners. It also defines and describes the GEOINT Enterprise, which encompasses a wide range of U.S and foreign entities that contribute to and influence the function of GEOINT. The Governance section describes the role of the GEOINT Functional Manager, the functional management governance structure, and related NSG organizations and forums. It also includes information on the governance structure of our Commonwealth partners, who have a significant impact on U.S. Government GEOINT activities.

GEOINT COMMUNITY

THE NATIONAL SYSTEM FOR GEOSPATIAL INTELLIGENCE (NSG)

The term "NSG" is used to describe the U.S. Government community, capabilities, assets, and other aspects of GEOINT that support U.S. national security decision making and U.S. military operations. The full definition of the NSG, shown in the box below, is established in both national Intelligence Community and DoD GEOINT doctrine. The NSG Community consists of Members and Partners.

NSG Members

NSG Members are IC and DoD organizations that fall under GEOINT Functional Management authorities, as outlined in EO 12333, DoD Directive 5105.60, and Intelligence Community Directive 113. NSG Members include the IC, the Joint Staff, the Military Departments (including the Services), and Combatant Commands (CCMDs).

National System for Geospatial Intelligence (NSG): The NSG is the combination of technology, policies, capabilities, doctrine, activities, people, data, and organizations necessary to produce GEOINT in an integrated multi-intelligence, multi-security domain environment. Its mission is to create an integrated, collaborative community of common practice promoting the GEOINT discipline across a diverse group of producers and consumers. It consists of members and partners that produce and employ GEOINT across the full range of national, military, and civil domains.

NSG MEMBERS

THE INTELLIGENCE COMMUNITY

Intelligence Agencies
- Central Intelligence Agency
- Defense Intelligence Agency
- National Geospatial-Intelligence Agency
- National Reconnaissance Office
- National Security Agency

Intelligence Components:
- Air Force Intelligence
- Army Intelligence
- Coast Guard Intelligence
- Marine Corps Intelligence
- Naval Intelligence
- Federal Bureau of Investigation (Office of Intelligence)
- Dept. of Energy (Office of Intelligence)
- Dept. of Homeland Security (Directorate of Intelligence & Analysis)
- Dept. of State (Bureau of Intelligence and Research)
- Dept. of Treasury (Office of Intelligence Support)
- Drug Enforcement Administration (Office of National Security Intelligence)

THE JOINT STAFF

MILITARY DEPARTMENTS
- Dept. of the Army (US Army)
- Dept. of the Air Force (US Air Force)
- Dept. of the Navy (US Navy and US Marine Corps)

COMBATANT COMMANDS
- US Africa Command (AFRICOM)
- US Central Command (CENTCOM)
- US Cyber Command (CYBERCOM)
- US European Command (EUCOM)
- US Northern Command (NORTHCOM)
- US Pacific Command (PACOM)
- US Southern Command (SOUTHCOM)
- US Special Operations Command (SOCOM)
- US Strategic Command (STRATCOM)
- US Transportation Command (TRANSCOM)

Approved for public release, 18-142

NSG PRINCIPAL PARTNERS

NSG Principal Partners include U.S. federal and civil agencies, allied Commonwealth countries, and certain members of U.S. industry, academia, and non-profit organizations. These Partners are organizations with which NSG Members work on a consistent basis. However, NSG Members continuously develop other U.S. and foreign partnerships, often just for the duration of specific missions and situations.

PRINCIPAL PARTNERS

U.S. FEDERAL AND CIVIL AGENCIES

NSG Member-organizations are closely linked with a number of federal agencies—such as the Defense Logistics Agency and Defense Information Services Agency—and work with most U.S. civil agencies via the Civil Applications Committee (CAC). The CAC is an interagency committee that facilitates the appropriate civil uses of remote sensing technologies and data collected by military and intelligence overhead capabilities, including commercial capabilities. This Committee is chaired by the USGS Director or his/her delegate on behalf of the Secretary of Interior, and the Vice Chair is a senior executive from a non-DOI member organization. The CAC is comprised of Principal Members (Federal civil organizations), Associate Members (IC and DoD organizations) and Ex-Officio Members. Principal members include the Departments of Interior, Agriculture, Commerce, Health and Human Services, and Transportation, as well as the U.S. Army Corps of Engineers, U.S. Coast Guard, Environmental Protection Agency, Federal Emergency Management Agency, National Science Foundation, National Aeronautics and Space Agency, and Tennessee Valley Authority.

The Civil Applications Committee (CAC): The CAC is an interagency committee that facilitates the appropriate civil uses of remote sensing technologies and data collected by military and intelligence overhead capabilities, including commercial capabilities.

U.S. FEDERAL & CIVIL AGENCY MEMBERS

CIVIL APPLICATIONS COMMITTEE (CAC)

- Department of Agriculture
- Department of Commerce
- Department of Health and Human Services
- Department of Interior*
- Department of Transportation
- Environmental Protection Agency
- Federal Emergency Management Agency
- National Science Foundation
- National Aeronautics and Space Administration
- Tennessee Valley Authority
- U.S. Army Corps of Engineers
- U.S. Coast Guard

OTHER U.S. FEDERAL AGENCIES

- Defense Information Services Agency
- Defense Logistics Agency
- Other

*The Department of Interior's U.S Geological Survey (USGS) serves in key roles as Chair of the Civil Applications Committee and voting member of the National Geospatial Intelligence Committee (GEOCOM).

ALLIED COMMONWEALTH COUNTRIES

NSG Principal Partners in the Commonwealth countries are represented by an organization body known as the Allied System for Geospatial Intelligence (ASG). The ASG manages the relationship of the geospatial intelligence organizations of the Commonwealth Allied partners (Australia, Canada, New Zealand, United Kingdom) and the United States. Each nation is represented by its lead GEOINT organization(s) and is an equal partner in the coalition. The United States provides the permanent Chair of the ASG Senior Management Council (ASMC) and the ASG Coordination Executive (ACE), which serve functions similar to that of the NSMC and GEOCOM (described in the Governance Section) respectively.

The Allied System for Geospatial Intelligence (ASG): The ASG manages the relationship of the geospatial intelligence organizations of the Commonwealth Allied partners—Australia, Canada, New Zealand, United Kingdom—and the United States.

ASG MEMBERS

- Australia
- Canada
- New Zealand
- United Kingdom
- United States

THE GEOINT ENTERPRISE

The term "GEOINT Enterprise" is used to describe the full breadth of U.S. and foreign government, commercial, and academic entities that produce, use, or contribute to one or more of the three elements of GEOINT (imagery, imagery intelligence, and geospatial data), and thereby influence the entire function. Given the widespread use and practice of GEOINT, it is essential to maintain awareness of activities and advancements occurring throughout the entire GEOINT Enterprise.

GEOINT Enterprise: The combination of technology, data, people, policies, capabilities, doctrine, activities, and organizations necessary to produce GEOINT in any government, academic, or commercial environment in the U.S. and partner countries.

THE GEOINT ENTERPRISE COMMUNITY

NSG MEMBERS
- Intelligence Community
- Joint Staff
- Military Departments
- Combatant Commands

ASG
- Australia
- Canada
- New Zealand
- United Kingdom
- United States

INTERNATIONAL GEOINT ENVIRONMENT
- Foreign Governments
- Foreign Industry
- Foreign Academic Institutions

OTHER U.S. PARTNERS
- U.S. Industry
- U.S. Academic Institutions
- U.S. State, Local, Tribal Organizations
- U.S. Law Enforcement

FEDERAL & CIVIL ORGANIZATIONS

Civil Applications Committee (CAC)
- Dept. of Agriculture
- Dept. of Commerce
- Dept. of Health & Human Services
- Dept. of Interior
- Dept. of Transportation
- Environmental Protection Agency
- Federal Emergency Management Agency
- National Science Foundation
- National Aeronautics and Space Administration
- Tennessee Valley Authority
- U.S. Army Corps of Engineers
- U.S. Coast Guard

Other U.S. Federal Agencies
- Defense Information Services Agency
- Defense Logistics Agency
- Other

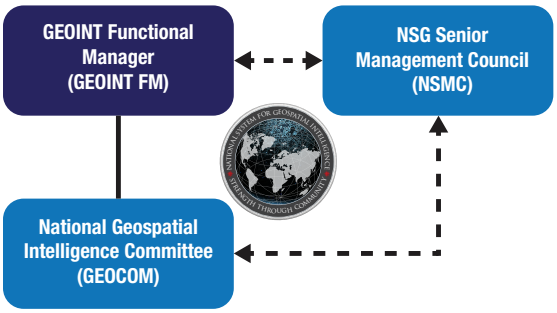
The term Global GEOINT Enterprise is sometimes used to emphasize the international aspects of the GEOINT Enterprise, but there is no difference between the terms or the communities associated with them.

Approved for public release, 18-142

NSG GOVERNANCE

The NSG is led by the GEOINT Functional Manager (GFM) in concert with a DNI-mandated "Committee of Record" and a GFM-appointed advisory council composed of members of the U.S. Government GEOINT Community. Each governing body has an important role to play in the management and future planning of the GEOINT function, and ensures that the GFM receives input from a wide range of users and producers of GEOINT. This section outlines the roles and responsibilities of the GFM and each governing body. Of note, the ASG has a parallel construct to the NSG framework.

Geospatial Intelligence Governing Framework



The three elements of the NSG governing structure are interdependent and serve collectively to advance the GEOINT function. The GFM may directly task the GEOCOM.

GEOINT Functional Manager (GFM): Executive Order 12333, "United States Intelligence Activities," as amended in 2008, legally designates the Director of NGA (D/NGA) as the GEOINT Functional Manager (GFM) for the Intelligence Community. Department of Defense Directive (DoDD) 5105.60, "National Geospatial-Intelligence Agency," 2009, designates the D/NGA as the DoD GEOINT Manager. The title GFM refers to both roles, thereby encompassing the Intelligence Community and DoD. The GFM is the authoritative GEOINT advisor to the Director of National Intelligence (DNI) and the Secretary of Defense.

The Functional Manager's role is defined by both obligations and authorities. Intelligence Community Directive (ICD) 113 "Functional Managers," 2009, states that a functional manager's primary obligation is to "oversee and guide the function in a manner that is distinct from organizational affiliations." Functional managers have other obligations as well, such as "maintaining knowledge of the totality of activities and resources pertaining to the function," and they "are accountable for continuously improving the performance of the function and for enhancing cross-function integration." ICD 113 and DoDD 5105.60 provide details on the full range of GFM authorities and responsibilities, such as issuing GEOINT standards for the DoD and IC. Please reference those documents for additional details.

NSG Senior Management Council (NSMC): Chaired by the GFM, the National System for Geospatial Intelligence (NSG) Senior Management Council, or NSMC, is the senior, three-star equivalent functional management advisory council of the NSG. Members discuss strategic, community-wide GEOINT issues and jointly address areas of common concern. The GFM brings a variety of issues before the NSMC for review, deliberation, endorsement, and/or decision. Commonwealth "Five Eyes (FVEY)" counterparts and issues are included at the discretion of the GFM. (FVEY is a term often used in classification of documents to indicate that the information can be shared with the five members of the Allied System for Geospatial Intelligence, or ASG.)

Geospatial Intelligence Committee (GEOCOM): The GEOCOM is a DNI-chartered forum for GEOINT. This Committee also provides a venue for community members to discuss, coordinate, and vote on substantive issues of common concern, and to develop recommendations on high-priority issues for the GFM or DNI. The GEOCOM is comprised of civilian Senior Executive Service (SES)/DISL and military Flag Officer (GOFO)-level members from key government GEOINT stakeholders, including the IC, DoD, and federal civil agencies, which are represented by the Civil Applications Committee (CAC)—a permanent NSG Partner. The GEOCOM administers subcommittees and working groups composed of subject matter experts from GEOCOM-member organizations. Each subcommittee is responsible for a specific GEOINT discipline such as collection, information systems and architecture, analysis and production, and training and professional development.

ABBREVIATIONS AND ACRONYMS

3D	Three Dimensional
ABI	Activity-Based Intelligence
ACE	ASG Coordination Executive
ASG	Allied System for Geospatial Intelligence
ASMC	ASG Senior Management Council
CAC	Civil Applications Committee
CCMD	Combatant Command
DCGS	Distributed Common Ground System
DISL	Defense Intelligence Senior Leader
DNI	Director of National Intelligence
DoD	Department of Defense
EEI	Essential Elements of Information
EM	Electromagnetic
EO	Electro-Optical
E.O.	Executive Order
FMV	Full Motion Video
FVEY	Five Eyes
GEOCOM	Geospatial Intelligence Committee
GEOINT	Geospatial Intelligence
GFM	GEOINT Functional Manager
GI&S	Geospatial Information and Services
GOFO	General Officer/Flag Officer
HSI	Hyperspectral Imaging
HUMINT	Human Intelligence
IC	Intelligence Community
ICD	Intelligence Community Directive
IFSAR	Interferometric Synthetic Aperture Radar
IMINT	Imagery Intelligence
INT	Intelligence Discipline
IR	Infrared
LIDAR	Light Detecting and Ranging (Also can be written as the word “lidar”)
MALE	Medium Altitude Long Endurance
MASINT	Measurement and Signatures Intelligence
MSI	Multispectral Imaging
MTI	Moving Target Indicator
NGA	National Geospatial-Intelligence Agency
NCL	NSG Consolidated Library
NSG	National System for Geospatial Intelligence
NSMC	NSG Senior Management Council
OBP	Object-Based Production
ODNI	Office of the Director of National Intelligence
OPIR	Overhead Persistent Infrared
OSINT	Open Source Intelligence
PAN	Panchromatic
PoL	Patterns of Life
RADAR	Radio Detecting and Ranging (Also may be written as the word “radar”)
SAR	Synthetic Aperture Radar
SES	Senior Executive Service
SIGINT	Signals Intelligence
SOM	Structured Observation Management
SONAR	Sound Navigation and Ranging (Also may be written as the word “sonar”)

Approved for public release, 18-142

TERPS	Terminal Instrument Procedures
TIR	Thermal Infrared
UAV	Unmanned Aerial Vehicle
UGS	Unattended Ground Sensor
USD(I)	Undersecretary of Defense for Intelligence
WAMI	Wide Area Motion Imagery

GLOSSARY

Activity-Based Intelligence (ABI): ABI refers to a methodology and automated technical process that contributes to intelligence analysis and products. It is defined as "An IC analytic method applied to structured data from all sources, to discover objects, relationships, or behaviors by resolving significant activity." Most GEOINT products focus on a specific object or area and seek to analyze everything about it. ABI enables more complex analysis by linking human, vehicular, and other activity related to the object or area, which can lead to different areas or objects and show patterns.

Aeronautical Analysis: A tradecraft involving the analysis and exploitation of worldwide aeronautical data and other sources in support of safety of navigation and national security goals, concerns, requirements, and strategies.

Aeronautical Data: Aerial Safety of Navigation data such as vertical obstructions, no-fly zones, flight routes, approach procedures, airfield infrastructure and layout, and aeronautical charts.

Applied Sciences: A tradecraft involving the analysis of the Earth's gravity and magnetic fields, geophysical structure, material properties, and dynamics for geospatial intelligence and DoD applications. Professionals in the applied sciences provide in-depth technical expertise on Geodetic and geophysical issues and satellite issues.

Assessment Products: Provide analysis of what is shown in an image or on a map, and provide information on the "who, what, when, where, how, and why," usually in the context of the purpose or mission for which it has been developed.

Base Layer: The first layer of a GEOINT product, also called the Foundation Layer, which consists of any combination of the three components of GEOINT: imagery, imagery intelligence, and geographic information. The base/foundation usually* is a map or image of a specific location and shows visible terrain, objects, and other features in that location. GEOINT images and maps contain highly accurate geo-coordinates of the location shown, as well as of any object or feature depicted in the map or image. *In some cases, the processed data itself is the product.

Cartography: The art and science of expressing graphically, by maps and charts, the known physical features of the Earth, or of another celestial body.

Detection Products: Designed to find natural and manmade materials that are not visible or easily identifiable to the human eye. A variety of EO or radar sensor phenomenologies and specialized data processing techniques are used to develop detection products. These products may be used for many purposes, such as to "see" beneath foliage and camouflage or to identify heat and other emissions.

Electro-Optical (EO): EO derives data from the ultraviolet through the infrared portions of the electromagnetic (EM) spectrum. Each part of the EM spectrum provides a different type of data or magnifies the results of the data, depending on the phenomenology used. Electro-optical sensors include panchromatic (visible), infrared, spectral (multispectral and hyperspectral), and light detection and ranging (lidar).

Elevation Data: Information about the height of objects on or in relation to the Earth. Elevation data includes heights of objects above the surface of the Earth, (spaceborne and airborne), on the surface of the Earth (buildings and physical relief), and below the surface (bathymetry and underground facilities).

Foundation Layer: See definition of Base Layer.

Full Motion Video (FMV): FMV, typically an EO capability, uses many still frames per second, creating a near-real-time video capability, which may be displayed as visible or infrared and may be recorded by digital or analog means. This near-real time capability allows observation of rapidly developing events and is a valuable tool for ongoing operations. It is also useful for continuous observation of an object to analyze its patterns over a long period of time.

Approved for public release, 18-142

Geodetic Data: Terrestrial, airborne, and satellite data used to scientifically measure the size, shape, and parameters of the earth, model the gravity field of the earth, and compute three-dimensional positions and coordinates of points above, on, and below the surface of the earth. This data has an impact on geo-positional systems (GPS), navigation tools, and systems of map grids and coordinate systems.

Geographic Names and Boundaries: Names and boundaries of cities, towns, provinces, regions, states, and countries. Identification of major landmarks, facilities, and buildings.

GEOINT: See the definition for Geospatial Intelligence.

GEOINT Collections: A GEOINT tradecraft involving collaboration with customers and source providers to develop comprehensive multi-INT, multi-source strategies to address intelligence problems. Professionals in this field create tasking and dissemination requirements, adjudicate requirements, analyze and investigate collection performance, assess and report on the end-to-end GEOINT system performance data, and advise customers in support of the National System for Geospatial-Intelligence (NSG).

GEOINT Enterprise. The combination of technology, data, people, policies, capabilities, doctrine, activities, and organizations necessary to produce GEOINT in any government, academic, or commercial environment in the U.S. and partner countries.

GEOINT Functional Manager (GFM): The authoritative advisor to the Director of National Intelligence (DNI) and Secretary of Defense, though the Undersecretary of Defense for Intelligence (USD(I)), on GEOINT issues and resources. Executive Order 12333, "United States Intelligence Activities," as amended in 2008, legally designates the Director of NGA (D/NGA) as the GFM for the Intelligence Community. Department of Defense Directive (DoDD) 5105.60, "National Geospatial-Intelligence Agency," 2009, designates the D/NGA as the DoD GEOINT Manager. The title GFM refers to both roles, thereby encompassing the Intelligence Community and DoD.

Geospatial Analysis: The science of extracting meaning from geospatial data and using geographic information systems to uncover and investigate relationships and patterns in all forms of geospatial data to answer intelligence or military issues. A scientific discipline that brings physical and human geography together in a digital environment in order to solve problems with regard to spatial analysis, physiography, socio-cultural aspects, and temporal relationships.

Geospatial Data Management: A tradecraft involving management of the development, approval, and population of geospatial data within NGA's feature/geospatial information database to ensure that it can be used to satisfy customer requirements. Requires knowledge of the wide range of products and a solid understanding of the capabilities of various systems used to support the extraction, analysis, and finishing of in-house, co-production, commodity, and contract data.

Geospatial Information: "Information that identifies the geographic location and characteristics of natural or constructed features and boundaries on the earth and includes: statistical data; information derived from, among other things, remote sensing, mapping, and surveying technologies; and mapping, charting, geodetic data, and related products." (This legal definition is in Title 10 of the U.S. Code, Section 467.)

Geospatial Information and Services (GI&S): The collection, information extraction, storage, dissemination, and exploitation of geodetic, geomagnetic, imagery, gravimetric, aeronautical, topographic, hydrographic, littoral, cultural, and toponymic data accurately referenced to a precise location on the Earth's surface.

Geospatial Intelligence (GEOINT): "The exploitation and analysis of imagery and geospatial information to describe, assess, and visually depict physical features and geographically referenced activities on the earth. Geospatial intelligence consists of imagery, imagery intelligence, and geospatial information." (Statutory definition codified in Title 10 of the U.S. Code, Section 467 (5)). Imagery, imagery intelligence, and geospatial information are defined separately in the glossary. Any one or combination of these three elements may be considered GEOINT.

GEOCOM: See the definition for "National Geospatial Intelligence Committee."

Geospatial Layer: A product layer composed of geospatial information including boundaries, infrastructure (such as sewer lines, power grids), elevation data, human geography data (population, cultural, political/religious geography), and identification of key facilities and natural or manmade features.

Global GEOINT Enterprise: A term sometimes used to emphasize the international aspects of the GEOINT Enterprise, but there is no difference between the terms or communities associated with them.

Human Geography (component of geospatial information): A social science discipline based on analyzing interconnections between people and places, including patterns of human activities, in the context of their environment. It also seeks to explain how actions taken in one place/population can impact another place/population. Human Geography includes sub-disciplines such as: population geography, political geography, cultural geography, and religious/ethnic geography. It may include both classified and unclassified information.

Human Geography (tradecraft): The art and science of understanding, representing, and forecasting activities of individuals, groups, organizations, and social networks with a geo-temporal context. Human Geography professionals gather, assess, and evaluate source materials and ensure its quality and suitability to build foundational data and apply knowledge and expertise in physical, socio-cultural, and political aspects of countries, regions, and urban areas to support national security goals, concerns, and strategies. This data is analyzed to characterize events, discover relationships and trends, infer conclusions, and predict behaviors.

Human Intelligence (HUMINT): Intelligence obtained through clandestine or overt HUMINT activities, or operations and activities utilizing human sources or other human assets.

Hyperspectral Imaging (HSI): An electro-optical phenomenology similar to MSI but uses hundreds, rather than tens, of bands of the visible and infrared portions of the EM spectrum. These extra bands can provide greater fidelity and characteristics than MSI. For example, HSI allows users to detect materials by their unique spectral signature.

Interferometric Synthetic Aperture Radar (IFSAR): A radar phenomenology that uses a SAR sensor to observe a location from two separate positions. This method generates elevation data of the Earth's surface.

Imagery: A likeness or presentation of any natural or man-made feature or related object or activity and the positional data acquired at the same time the likeness or representation was acquired, including products produced by space-based national intelligence reconnaissance systems, and likenesses or presentations produced by satellites, airborne platforms, unmanned aerial vehicles, or other similar means. (This legal definition is in Title 10 of the U.S. Code, Section 467.)

Imagery Analysis: The science of converting information, extracted from imagery, into intelligence about activities, issues, objects, installations, and /or areas of interest.

Imagery Intelligence (IMINT): The technical, geographic, and intelligence information derived through the interpretation or analysis of imagery and collateral materials. (This legal definition is in Title 10 of the U.S. Code, Section 467.)

Imagery Science: Tradecrafts involving the generation, collection, duplication, analysis, modification, and visualization of images. It includes the use of advanced techniques to identify objects that cannot be detected by the human eye. Imagery science is used to develop algorithms, evaluate tools, and create customized methodologies and products to address a variety of geospatial intelligence problems. Imagery scientists typically specialize in precision mensuration, radar, spectral, infrared, and other specialized collection systems.

Infrared (IR): IR is an electro-optical phenomenology that uses the infrared part of the spectrum to detect heat and radiance/reflection, and displays that information in a gray-scale image.

Intelligence Layer: A GEOINT product layer customized for a specific mission or purpose that consists of information derived from various intelligence sources, or a combination of those sources. Examples include locations of friendly and enemy forces,

Approved for public release, 18-142

presence of chemical or biological hazards, weapons facilities, routes and alternatives, and potential targets. GEOINT serves as a base for the depiction of data from other intelligence disciplines (INTs), including Human Intelligence (HUMINT), Signals Intelligence (SIGINT), Measures and Signatures Intelligence (MASINT) and Open Source Intelligence (OSINT).

Light Detection and Ranging (Lidar): An electro-optical phenomenology that uses laser pulses in the visible and infrared portions of the EM spectrum. The sensor emits a pulse of laser light toward an object, which reflects back some of the energy to the sensor. The time it takes for the energy to return provides elevation values—shorter roundtrips indicate higher elevations and longer roundtrips indicate lower elevations. This process helps measure distances to, heights of, and other characteristics of an object. The process can be used to develop three-dimensional models of an object, such as a building.

Maritime Analysis: A GEOINT tradecraft involving acquisition, analysis, compilation, and dissemination of maritime safety information to populate and update nautical databases to support the Digital Nautical Chart, hardcopy charts, digital publications, and Electronic Chart Display and Information Systems. Marine Analysts generate mission specific datasets, promulgate worldwide navigational warnings, and respond to queries from foreign hydrographic offices and the users of our products and services.

Maritime Data: Maritime Safety of Navigation data such as shipping routes, underwater obstructions, sailing restrictions, port infrastructure and layout, approach procedures, bathymetry, soundings, and nautical charts.

Measurement and Signature Intelligence (MASINT): Scientific and technical intelligence information obtained by quantitative and qualitative analysis of the physical and technical attributes of data. MASINT, which is derived from specific technical sensors, identifies distinctive features associated with the source, emitter, or sender. It can measure physical characteristics of targets and events of interest to determine composition, location, and/or performance.

Mission/Event Preparation Products: Used to prepare for a mission, operation, or major event. These products focus on familiarization with the area, including identification of key landmarks and existing or potential hazards. They usually are map or imagery products that facilitate safety of navigation by identifying elements such as buildings, routes, water depth, terrain features, obstacles, and threats. The products assist with activities such as route planning and security preparations.

Mission Layer: A GEOINT product layer that provides general information relevant to the purpose and area for which the product is being used. The information may include weather conditions, logistics data, characteristics of the local terrain, population, and government, and other data obtained through commonly used, unclassified sources.

Motion GEOINT: Both EO and radar sensors can create or capture motion by collecting two or more frames per second. This activity is known as Motion GEOINT. The most common types are Full Motion Video (FMV), Moving Target Indicator (MTI), and Wide Area Motion Imagery (WAMI).

Moving Target Indicator (MTI): This EO and radar capability shows only those objects that are in motion, and provides information on the speed and direction that objects are moving.

Multispectral Imaging (MSI): MSI is an electro-optical phenomenology that provides a color image by using tens of additional bands of the visible and infrared portions of the spectrum. It also provides more detail to images, showing characteristics that are not otherwise visible.

National Geospatial Intelligence Committee (GEOCOM): The GEOCOM is a Director of National Intelligence-chartered forum to discuss, coordinate, and vote on substantive issues in order to provide recommendations to the GEOINT Functional Manager. It is comprised of Senior Executive Service and General Officer/Flag Officer-level members from key government GEOINT stakeholders, including the IC, military Services, Combatant Commands, the U.S. Geological Survey and civil agencies, which are represented by the Civil Applications Committee (CAC). The GEOCOM manages subcommittees and working groups composed of subject matter experts from GEOCOM-member organizations. Each subcommittee focuses on a different substantive area such as collection, information systems and architecture, analysis and production, and training and professional development.

National System for Geospatial Intelligence (NSG): The combination of technology, policies, capabilities, doctrine, activities, people, data, and organization necessary to produce GEOINT in an integrated, multi-intelligence, multi-security domain environment. It includes members and partners that produce and employ GEOINT across the full range of national, military, and civil domains.

NSG Senior Management Council (NSMC): Chaired by the GFM, the NSMC is the senior, three-star equivalent functional management advisory council of the NSG. Members discuss strategic, community-wide GEOINT issues and jointly address areas of common concern. The GFM brings a variety of issues before the NSMC for review, deliberation, and/or decision. Five Eyes (FVEY) counterparts and issues are included at the discretion of the GFM.

Object: Representations of physical objects of interest, such as a person, unit, facility, or type of equipment.

Object-Based Production (OBP): The process of formatting and organizing intelligence related to objects. This structured approach enables automated identification of the object, or identical objects, and access to all sources of known information about that object. It also facilitates Activity Based Intelligence analysis.

Observation: Information or image gleaned from data captured by a sensor.

Open Source Intelligence (OSINT): Intelligence produced from publicly available information that is collected, exploited, and disseminated in a timely manner to an appropriate audience for the purpose of addressing a specific intelligence requirement.

Overhead Persistent Infrared (OPIR): OPIR sensors operate in the visible and near infrared, short-wave infrared, and mid-wave infrared portions of the spectrum to characterize this energy as an event or process it as a scene. OPIR sensors provide persistent (i.e. continuous) coverage of mission areas and energy radiation detection from both tactical and strategic targets including missiles launches and events, wildfires, enemy hostilities, weather, volcanos, and weapons characterization.

Panchromatic (PAN): PAN uses the visible part of the EM spectrum, along with a portion of IR spectrum, and produces an image similar to a black and white aerial photograph. The images can provide a very detailed and accurate likeness of an area or object, and can show shadows and other effects that help identify characteristics of an object or environment.

Phenomenology: The study of natural occurring and measurable activity (e.g., effluent emission as a result of a chemical reaction). As used in this document, it refers to sensor technology, literal and non-literal, which allows discovery, observation, and characterization of natural and measurable occurrences (spatial, spectral, radiometric and temporal). Various phenomenologies discussed in Publication 1.0 include electro-optical imagery, multispectral imagery, hyperspectral imagery, light detection and ranging, and radar.

Platform: The vehicle to which one or many sensors are attached. Platforms include satellites, aircraft (known as “airborne” platforms, and include unmanned aerial vehicles, balloons, and dirigibles), ground-based (for example, vehicles, stationary objects such as poles, and humans who carry sensors), and water-based platforms (such as ships, submarines, sonars and buoys).

Radar: Active sensors that emit manmade electromagnetic energy to illuminate the environment or object they are imaging, and then use the characteristics of the response to create an image. These sensors use reflected radar energy to illuminate objects in day or night and in almost any weather conditions. A radar image is non-literal, which means it does not appear as a photo that shows an exact likeness of an object or environment. It is similar to an X-ray of an area or object, with the ability to detect characteristics that a literal picture would not show. An important feature is that it can be used for poor light and weather conditions in which EO technologies are ineffective.

Approved for public release, 18-142

Sensor: A technical device designed to detect and respond to at least one stimulus and that may record and/or transmit a resultant impulse for interpretation or measurement. Two primary categories of sensors are electro-optical (EO) and radar, both of which have several types or variants, known as phenomenologies. Sensors may be active or passive, as described below.

- Active Sensor: Sensors that generate the electromagnetic energy needed to illuminate the object that is being imaged. They broadcast energy and process returning portions of it in order to image a targeted area. Active imagery sensing capabilities include real-aperture radar, synthetic aperture radar, interferometric synthetic aperture radar, moving target indicator, and light detection and ranging systems.

- Passive Sensor: Sensors that use natural electromagnetic energy sources such as the sun, naturally occurring radiation, or objects that generate heat. They generate data by capturing the reflected or emitted electromagnetic energy from an object. Passive sensors, which operate in "receive" mode and do not emit energy, diminish the adversary's ability to detect the fact that they are being imaged. Electro-optical sensors (except lidar) are passive.

Signals Intelligence (SIGINT): A form of technical intelligence derived from the exploitation of foreign electronic emissions. SIGINT can be in the form of the actual information content of a signal or in the form of its temporal and spectral characteristics, called signal operating parameters. SIGINT includes both the raw data and the analysis product of that data. This category of intelligence includes all Communications Intelligence, Electronic Intelligence, and Foreign Instrumentation Signals Intelligence.

Structured Observation Management (SOM): An organized method to capture, store, standardize, and provide data and information from GEOINT sources (sensors). This approach decreases the time required for analysts to search for data, enabling them to focus on conducting analysis and developing products.

Synthetic Aperture Radar (SAR): A radar phenomenology that illuminates an object with pulses of microwave energy. It applies signal processing to a series of many pulses to produce imagery.

Terminal Instrument Procedures (TERPS): Process of data extraction and analysis to produce Department of Defense Instrument Approach Procedures. Analysis includes imagery derived features, host nation, and vertical obstruction data.

Thermal Infrared (TIR): TIR is a type of Infrared phenomenology, but uses different wavelengths of the infrared spectrum to indicate the temperature level of the heat or radiance/reflection. The shape and size of the object or environment emitting heat is shown as a different shade than the rest of the image. Cooler objects are darker, warmer objects are lighter, and hot objects are bright white.

Topographic Data: Ground/surface-related information including infrastructure (roads, power grids), man-made features, population data, vegetation, and hydrography.

Wide Area Motion Imagery (WAMI): A set of motion imagery sensors with a wide field of view (FOV) diameter of up to 8 km, which provides persistent surveillance of a broad area of coverage. WAMI data enables forensic backtracking of kinetic events, network analysis, pattern of life (PoL) studies, and security monitoring.

Appendix B: GEOINT DEFINTION

(Including Amplifications)

Exact language from:

- *NSG GEOINT Basic Doctrine (2018)*
- *Title 10, U.S. Code, Section 467 (2005 & 2010)*
- *DoD Directive 5105.60 (2009)*
- *Director of National Intelligence Memo (2005)*

NSG GEOSPATIAL INTELLIGENCE (GEOINT) BASIC DOCTRINE: PUB 1.0,

(Updated in 2018)

This GEOINT Definition contains the same language as the Title 10, Section 467 Definition (shown in next entry) but provides slight changes in organization to improve clarity and readability.

GEOINT DEFINITION

"The term 'geospatial intelligence' means the exploitation and analysis of imagery and geospatial information to describe, assess, and visually depict physical features and geographically referenced activities on the earth. Geospatial intelligence consists of imagery, imagery intelligence, and geospatial information."

- **Imagery.** "A likeness or presentation of any natural or man-made feature or related object or activity and the positional data acquired at the same time the likeness or representation was acquired, including products produced by space-based national intelligence reconnaissance systems, and likenesses or presentations produced by satellites, airborne platforms, unmanned aerial vehicles, or other similar means." Imagery includes handheld photography, but "does not include handheld or clandestine photography taken by or on behalf of human intelligence collection organizations."
- **Imagery Intelligence.** "The technical, geographic, and intelligence information derived through the interpretation or analysis of imagery and collateral materials."
- **Geospatial Information.** "Information that identifies the geographic location and characteristics of natural or constructed features and boundaries on the earth, including: statistical data; information derived from, among other things, remote sensing, mapping, and surveying technologies; and mapping, charting, geodetic data, and related products."

TITLE 10, US CODE: ARMED FORCES

(2005)

Subtitle A – General Military Law
PART I – Organization and General Military Powers
CHAPTER 22 – National Geospatial-Intelligence Agency
SUBCHAPTER I – Missions and Authority
§ 467. "Definitions"

§ 467. Definitions

Release date: 2005-07-12

In this chapter:
(1) The term "function" means any duty, obligation, responsibility, privilege, activity, or program.
(2)
(A) The term "imagery" means, except as provided in subparagraph (B), a likeness or presentation of any natural or man-made feature or related object or activity and the positional data acquired at the same time the likeness or representation was acquired, including—
I. products produced by space-based national intelligence reconnaissance systems; and
II. likenesses or presentations produced by satellites, airborne platforms, unmanned aerial vehicles, or other similar means.
(B) Such term does not include handheld or clandestine photography taken by or on behalf of human intelligence collection organizations.
(3) The term "imagery intelligence" means the technical, geographic, and intelligence information derived through the interpretation or analysis of imagery and collateral materials.
(4) The term "geospatial information" means information that identifies the geographic location and characteristics of natural or constructed features and boundaries on the earth and includes—
(A) statistical data and information derived from, among other things, remote sensing, mapping, and surveying technologies; and
(B) mapping, charting, geodetic data, and related products.
(5) The term "geospatial intelligence" means the exploitation and analysis of imagery and geospatial information to describe, assess, and visually depict physical features and geographically referenced activities on the earth. Geospatial intelligence consists of imagery, imagery intelligence, and geospatial information.

*NOTE: Title 10, Section 442, was updated in 2010 to include language on the NGA Mission. The new paragraphs address systems and tasking, and do not impact the definition of GEOINT in Section 467. However, the language is shown below because it provides context to the handheld photography language in the definition.

Section 442(a) of title 10, United States Code, is amended—

by redesignating paragraph (2) as paragraph (3); (2) by inserting after paragraph (1) the following new paragraph (2): "(2) (A) As directed by the Director of National Intelligence, the National Geospatial-Intelligence Agency shall develop a system to facilitate the analysis, dissemination, and incorporation of likenesses, videos, and presentations produced by ground-based platforms, including handheld or clandestine photography taken by or on behalf of human intelligence collection organizations or available as open-source information, into the National System for Geospatial Intelligence.
"(B) The authority provided by this paragraph does not include authority for the National Geospatial-Intelligence Agency to manage tasking of handheld or clandestine photography taken by or on behalf of human intelligence collection organizations"; and (3) in paragraph (3), as so redesignated, by striking "paragraph (1)" and inserting "paragraphs (1) and (2)".

Approved for public release, 18-142

DODD 5105.60

"NATIONAL GEOSPATIAL- INTELLIGENCE AGENCY"
(July 29, 2009)

GLOSSARY, DEFINITIONS

GEOINT. The exploitation and analysis of imagery and geospatial information to describe, assess, and visually depict physical features and geographically referenced activities on the earth. Geospatial intelligence consists of imagery, imagery intelligence, and geospatial information (section 467 of Reference (a)). **[Pub 1.0 Note: the following portion of this definition was derived from a classified July 2005 ONDI/C memo]** GEOINT collection encompasses all aspects of: literal, infrared (IR) and synthetic aperture radar (SAR) imagery; overhead persistent infrared capabilities; and geospatial information and services. The terms imagery intelligence and advanced geospatial intelligence are encompassed within this definition of GEOINT. GEOINT includes the exploitation and analysis of electro-optical, IR, and radar imagery; and of geospatial, spectral, laser, IR, radiometric, SAR phase history, polarimetric, spatial, and temporal data. It employs all ancillary data, signature information, and fused data products, as necessary. Integrated GEOINT products may also include data and information from collateral sources.

Geospatial information. Defined in sections 455(c) and 467 of Reference (a) [Title 10, U.S. Code].

Imagery. Defined in section 467 of Reference (a) [Title 10, U.S. Code].

Imagery intelligence. Defined in section 467 of Reference (a)

DNI MEMO

"Statutory Definition of Geospatial Intelligence and its Amplification"
(17 October 2005)

2. The following amplifies the statutory definition [of GEOINT] and represents the full manifestation of NGA's missions per section 442(a) Title 10. The relevance of this amplification derives from the "terms of art" unique to the GEOINT discipline.

GEOINT encompasses all aspects of imagery (including capabilities formerly referred to as Advanced Geospatial Intelligence and imagery-derived MASINT) and geospatial information and Services (GI&S; formerly referred to as mapping, charting, and geodesy). It includes, but is not limited to, data ranging from the ultraviolet through the microwave portions of the electromagnetic spectrum, as well as information derived from the analysis of literal imagery; geospatial data, and information technically derived from the processing, exploitation, literal, and non-literal analysis of spectral, spatial, temporal, radiometric, phase history, polarimetric data, fused products (that is, products created out of two or more data sources), and the ancillary data needed for data processing and exploitation, and signature information (to include development, validation ,simulation, data archival, and dissemination). These types of data can be collected on stationary and moving targets by electro-optical (to include IR, MWIR, SWIR TIR, Spectral, MSI, HSI, HD), SAR (to include MTI), related sensor programs (both active and passive), and non-technical means (to included geospatial information acquired by personnel in the field).

3. The statutory definition, as amplified, provides the basis for a clear distinction between GEOINT and MASINT. The relevant Intelligence Community Directives should reflect this definition and amplification.

FOREWORD

Marine Corps Doctrinal Publication 2, *Intelligence*, and Marine Corps Warfighting Publication (MCWP) 2-1, *Intelligence Operations*, provide doctrine and higher order tactics, techniques, and procedures for intelligence operations. MCWP 2-15.4, *Imagery Intelligence*, complements and expands upon this information by detailing doctrine, tactics, techniques, and procedures for the conduct of imagery intelligence operations in support of the Marine air-ground task force (MAGTF). The primary target audience of this publication is intelligence personnel responsible for planning and execution of imagery intelligence operations. Personnel who provide support to imagery intelligence or who use results from these operations should also read this publication.

MCWP 2-15.4 describes aspects of imagery intelligence operations including doctrinal fundamentals, equipment, command and control, communications and information systems support, planning, execution, and training. MCWP 2-15.4 provides the information needed by Marines to understand, plan, and execute imagery intelligence operations in support of the MAGTF across the spectrum of conflict.

Reviewed and approved this date.

CHAPTER 1. FUNDAMENTALS

If you can't get behind enemy lines and peer around with your own good eyes, what's your next best bet? A photograph, isn't it?

—FMFRP 12-16, Front Line Intelligence

Imagery is the representation of objects reproduced electronically or by optical means on film, electronic display devices or other media.

Imagery, along with the graphical, geospatial, and textual intelligence products derived from it, is an increasingly critical element in the planning and decisionmaking efforts of commanders and supporting staffs at all echelons. Much of the imagery available to the Marine air-ground task force (MAGTF) commander requires detailed analysis by highly trained specialists to fully exploit its value. Imagery and imagery-related information—when processed, exploited, analyzed, and fused with other intelligence information—results in imagery intelligence (IMINT).

Principal sources of imagery and related data are national overhead intelligence systems such as satellites; manned aircraft such as the F-14 or F/A-18 with the advanced tactical airborne reconnaissance system (ATARS); the U-2 and the joint surveillance target attack radar system (JSTARS); unmanned aerial vehicles (UAVs); and various hand-held cameras.

Overview

IMINT Information vs. Intelligence

A critical distinction must be made when discussing, planning for, and executing IMINT operations and operations yielding imagery-related combat information. IMINT is the function performed by the G-2/S-2 that involves imagery analysis and integration with other intelligence activities to produce all-source intelligence products. The intelligence battalion's (intel bn's) imagery intelligence platoon (IIP), unit intelligence personnel, and Marine Corps Intelligence Activity (MCIA) conduct IMINT operations, planning, collecting, producing, and disseminating information or intelligence to the commander, staff, and major subordinate commands (MSCs). To provide imagery analysis for fusion into intelligence, specifically trained technical personnel, adequate time, and sophisticated equipment are required. Imagery and related combat and sensor data from JSTARS, UAVs, and various reconnaissance sources with hand-held cameras may sometimes be rapidly disseminated to tactical commanders to effect decisions without extensive intelligence processing and analysis. This type of intelligence support is provided directly to the tactical commander without being analyzed or evaluated against other intelligence. Caution should be exercised to ensure that the commander is apprised of the strong potential for misleading information when the provided intelligence is based on a single, unevaluated intelligence source.

IMINT aids commanders and planners primarily through two forms of support. First, IMINT provides situational awareness for the terrain, both natural and manmade, to support the commander's intelligence preparation of the battlespace (IPB) effort through various baseline IMINT and geographic intelligence (GEOINT) based studies such as helicopter landing zones (HLZs); beach, coastal, port and airfield studies; and gridded reference graphics (GRG). Second, support is provided through imagery as a confirming source of intelligence for another discipline such as signals intelligence (SIGINT) or human intelligence (HUMINT).

Objectives of IMINT

Reduce Uncertainty

IMINT must support the commander's decisionmaking process by reducing uncertainty about the hostile situation and the surrounding environment.

Counterintelligence and Force Protection

IMINT supports the identification of hostile intelligence collection operations; aids with the identification of MAGTF vulnerabilities that could be exploited by the enemy; and assists with the evaluation of friendly security measures to counter these.

Capabilities and Limitations of IMINT

Capabilities

IMINT is an extremely valuable part of intelligence. IMINT provides concrete, detailed, and precise information on the location and physical characteristics of both the threat and the environment. It is the primary source of information concerning key terrain features, installations, and infrastructure used to build detailed intelligence studies, reports, and target materials. Order of battle (OOB) analysis, enemy courses of action assessments, development of target intelligence, and battle damage assessment (BDA) are intelligence functions that rely heavily upon IMINT.

Limitations

The major limitations of IMINT are the time required to task, collect, process, analyze, and disseminate the imagery product; the detailed planning and coordination required to ensure the collected imagery is received in time to impact the decisionmaking process; and the requirement for considerable assets in personnel, equipment, and communications connectivity to conduct IMINT operations. Also, imagery operations can be hampered by weather; enemy air defense capability; and enemy camouflage, cover, concealment and deception activities.

Sensors

Appendix A describes the basic capabilities and limitations of electro-optical (EO), radar, and infrared imagery sensors.

Responsibilities and Products

Overview

The Marine Corps relies on a complementary mix of tactical, theater, and national IMINT sources to support its intelligence planning and operations. The MAGTF must use the full range of US intelligence capabilities, from national through theater to organic, in support of the assigned mission. Due to the nature of expeditionary operations, the employment of organic MAGTF intelligence collection assets within the assigned area of operations (AO) is not feasible until just prior to the introduction of forces. This means that national or theater intelligence assets must be relied upon for predeployment IMINT support.

The MAGTF will rely almost exclusively on external support during the planning and deployment phases of any operation. Even when employed, the MAGTF will continue to require national and theater support in specific areas to add depth to the reconnaissance effort and cover gaps in organic collection capabilities.

Marine Corps IMINT Responsibilities

The MAGTF G-2/S-2 has staff responsibility for intelligence, counterintelligence (CI), and reconnaissance, to include support of IMINT operations. In conjunction with the G-3/S-3, the G-2/S-2 develops the intelligence operations plan (appendix 16 to annex B), the supporting IMINT plan (appendix 7 to annex B), and the reconnaissance and surveillance (R&S) plan (appendix 14 to annex B), which allocate resources and assign specific imagery reconnaissance and supporting missions to MAGTF and supporting elements. Together, these intelligence plans assign intelligence missions,

reconnaissance missions, and tasks, and also allocate supporting resources.

Factors affecting the development of intelligence and supporting IMINT plans are—

- Priority intelligence requirements (PIR) and intelligence requirements, to include the specific intelligence questions to be answered for each.
- Communications connectivity and information systems capabilities available, both in IMINT units as well as in supported commands.
- Time available.
- Available information and intelligence from other sources.
- Redundancy required.
- Assets available.
- Knowledge of the enemy situation.
- Enemy counter-reconnaissance capabilities.

Based on these factors, the commander's intent, anticipated enemy activity, the MAGTF concept of operations, and the overall intelligence operations plan, the G-2/S-2 develops specific intelligence, reconnaissance, and imagery-related tasks. Individual units are assigned reconnaissance tasks per the intelligence plan. The intelligence support coordinator (ISC), under the staff cognizance of the MAGTF G-2/S-2, establishes an intelligence operations center (IOC) to perform intelligence requirements management, staff cognizance of ongoing organic and supporting collection operations, intelligence production and analysis, and intelligence dissemination. The following are the key elements within the IOC:

- **Support Cell.** Primary element for conducting Marine expeditionary force (MEF)-wide intelligence requirements management; weather support; collections and dissemination planning and direction; and intelligence staff cognizance of MEF organic and supporting intelligence and reconnaissance operations.
- **Surveillance and Reconnaissance Cell (SARC).** Primary element for supervising the execution of organic and supporting intelligence and reconnaissance plans.
- **Production and Analysis (P&A) Cell.** Primary production and analysis element of the MAGTF. Processes and produces all-source intelligence products in response to requirements of the MAGTF. Additionally, principal IMINT and GEOINT production element of the MEF.

MAGTF subordinate units also conduct intelligence and reconnaissance planning and operations in support of their own efforts through a variety of means. Close coordination with the ISC and IOC is essential to ensure overall effective MAGTF intelligence operations and intelligence support to all commanders. IMINT and imagery-related data and information are collected by a variety of assets, each with unique capabilities and limitations. The following MAGTF units and organizations are those most likely to be tasked with imagery-related collection missions and production support:

- Imagery intelligence platoon, intel bn.
- Marine unmanned aerial vehicle squadrons (VMUs).
- JSTARS common ground station (CGS).
- Marine fighter/attack (all weather) squadrons (VMFA[AW]s) F/A-18D.
- Marine light/attack helicopter squadron (HML/A).
- Ground reconnaissance units with Manpack secondary imagery dissemination system (SIDS) or tactical intelligence photographic (TACPHOTO) capability.

Types of IMINT Products

Major types of IMINT products include IMINT reports, hard copy prints, mosaics, overlays, annotated photographs, and various hard copy and electronic all-source intelligence products. See chapter 5 for a detailed discussion of imagery and IMINT products.

Related Terminology

Reconnaissance

A reconnaissance mission is undertaken to obtain, by visual observation or other detection methods, information about the activities and resources of an enemy or potential enemy, or to secure data concerning the meteorological, hydrographic, or geographic characteristics of a particular area. (JP 1-02)

Broad Area Coverage, Broad Area Search, and Directed Search Area

These imaging strategies provide a reconnaissance capability to cover large areas of the earth's surface. These techniques are especially suited for providing large area coverage for baseline studies of terrain and lines of communication. On the negative side, they take extended time to produce large format mosaic prints, are normally produced at a low National Imagery Interpretation Rating Scale (NIIRS) rating, and possess imagery quality of only fair to poor (see appendix B for a discussion of NIIRS).

Broad area coverage (BAC), also known as broad area search (BAS), are missions entailing imagery coverage of large areas of the earth's surface that enable analysis of a greater amount of area and provide the imagery needed for the creation of large area mosaics.

Directed search area (DSA) imagery missions identify a geographic region in the shape of a polygon that may contain from 3 to 24 corner points with latitude and longitude coordinates. This gives intelligence planners the flexibility to tailor intelligence collection and other operations plans to meet commanders' needs.

Route Reconnaissance or Lines of Communications Coverage

This imagery coverage is defined by a road, mobility corridor or other form of transportation passageway delineated by a specific start and end point. This type of reconnaissance is not limited to enemy areas but may be requested to facilitate friendly logistics or troop movements. The image product is normally produced as a variation of a standard mosaic, a strip map or as a GRG.

Battlefield Surveillance

Battlefield surveillance is the systematic observation of the battle area to provide timely information and combat intelligence. The primary difference between reconnaissance and surveillance is that reconnaissance is normally a single "look" while surveillance denotes a continuous observation. Surveillance is not normally considered a capability of the imagery process, with the exception of JSTARS and UAVs. Both the JSTARS and UAV platforms have endurance limitations that do allow for the long-term continuous observation often required for operational support.

Point Target

A point target is a specified imaging target that is normally less than 1 nautical mile in diameter. It is meant for higher resolution imagery such as EO NIIRS (see appendix B for a discussion of NIIRS) of 5.0 or better to provide the clarity of detail required for specific equipment identification or for precision targeting solutions. This type of target is best suited for static/semistatic targets that will require detailed analysis to answer specific PIR and intelligence requirements (IRs). Point targets are the most common technique used in imagery collection operations.

National Imagery

National imagery refers to imagery platforms under the control of a US Government agency such as the National Imagery and Mapping Agency (NIMA). These platforms normally consist of imagery satellites used for military operations, treaty verification, mapping, and foreign humanitarian assistance.

Theater Imagery

Theater imagery refers to the imagery platforms under the cognizance of the theater combatant commander. These may include airborne platforms such as the U-2, high altitude or extended endurance UAVs, and F-14 tactical aerial reconnaissance pod system (TARPS).

Organic Imagery

Organic imagery refers to all other types of imagery platforms organic to or under the control of the MAGTF commander. These platforms range from hand-held cameras with ground reconnaissance teams to F/A-18D ATARS aircraft.

IMINT vs. Imagery

IMINT is fully analyzed and evaluated imagery and supporting detailed intelligence text reports (which may also include information from other intelligence disciplines such as SIGINT), whereas imagery consists of the raw, unevaluated pictures of an area or target. An annotated target graphic represents IMINT while either the on-screen picture or prints from the screen of a downlinked UAV represent imagery in an unevaluated form.

Role and Functions

General

IMINT and other intelligence disciplines provide information regarding the enemy and the battlespace (weather and terrain) that help the commanders reduce uncertainty; identify opportunities for success; assess risk; outline their intent; make decisions that provide focus, generate speed, and tempo; and achieve decisive results.

IMINT provides MAGTF commanders operational and tactical intelligence support. Imagery and IMINT contribute to all six specific intelligence functions: support to the commander's estimate, situation development, indications and warning (I&W), force protection, targeting, and combat assessment. Specifically, IMINT assists intelligence personnel by providing commanders with I&W of hostile action; IPB; identification of enemy disposition, location, and strength; situational development to confirm or deny enemy intentions and courses of action; and BDA to allow continual assessment of the effectiveness of friendly attacks and their effects on enemy strengths, vulnerabilities, and capabilities.

Tactical IMINT Principles

Focus on Tactical Intelligence

National and theater imagery assets support the strategic and operational levels of war as well as tactical operations. MAGTF IMINT operations focus on the generation of tactical intelligence and utilization of strategic/operational IMINT for tactical purposes. However, consideration should always be given to required timelines for processing, exploitation, production, and dissemination of imagery and IMINT products in relation to the MAGTF operational tempo when selecting an imagery system to provide tactical support. For example, a theater system may not able to tailor imagery or IMINT in the format required of the battle area in a timely enough manner to support tactical I&W decisions.

Intelligence is Focused Downward

While the management of IMINT collection and production is centralized in the MAGTF command element (CE), the focus is on providing imagery support needed to plan and execute the mission to every unit involved in the operation.

Critical products will be pushed down to the tactical commander, who will be able to pull additional IMINT support as needed.

Intelligence Activities Require Centralized Management

Scarcity of IMINT assets, the broad geographic range and operational capabilities, and the requirement to focus IMINT resources on the commander's PIR require centralized coordination and management. This centralization will be done in the MAGTF IOC, under the direction of the intel bn commander as the ISC. Although centralized management is generally required to best plan and use IMINT resources, mission, enemy, terrain and weather, troops and support available-time available (METT-T) may require the MAGTF commander to either attach or place task-organized IMINT elements in direct support of MAGTF subordinate elements to satisfy their IRs.

G-2/S-2 Facilitates Utilization of Intelligence

The intelligence officer enables effective utilization of IMINT and all other intelligence and reconnaissance activities and products throughout the unit. As the principal disseminator of intelligence and a full and continuous participant in the planning process, the intelligence officer ensures that the full implications of the IMINT and overall intelligence picture are understood. This and the full intelligence operations mission are accomplished through three key subordinate officers. The first, the G-2 operations officer, is responsible for the provision and effective use of intelligence to the commanding general, the battlestaff, the current and future operations sections, and force fires. The second, the G-2 plans officer, is responsible for this support to the future plans team. Finally, the third is the intel bn commander as the assistant chief of staff (AC/S) G-2's ISC, having principal staff responsibility for the timely dissemination of intelligence throughout the MAGTF and ensuring it is understood, complete, and if any new IRs result from it.

Tailored and Timely Intelligence

Intelligence tailored to the requirements of the user provide a useful format, effect the development of pertinent IMINT and all-source intelligence products, and thus support decisionmaking. Dissemination of these intelligence products—not simply data, pictures or information—to the right place at the right time is the guiding principle of all intelligence dissemination activities.

Utilization: The Final Step

IMINT's value is derived from its support of decisionmaking. The IMINT intelligence cycle is not complete until the IMINT that has been developed is used to plan and/or execute operations. Central to this principle is the need for intelligence personnel to ensure that disseminated IMINT and other intelligence products have been received by all needing it; that they understand it; the degree to which it satisfies their previously stated IRs; and whether it leads to new IRs.

IMINT and the Intelligence Cycle

The IMINT cycle mirrors the intelligence cycle (see figure 1-1). These steps define both a sequential and an interdependent process for developing IMINT. These steps differ from the joint intelligence cycle in its emphasis on utilization of intelligence. Imagery-related data and intelligence should be passed directly to the appropriate user—depending upon the situation, either an intelligence command and control (C2) node or directly to commanders—to meet the requirement for rapid action related to the demands of current and future operations.

Planning and Direction

Planning and directing MAGTF IMINT operations includes:

- Determining IMINT intelligence collection requirements (ICRs) intelligence production requirements (IPRs), and intelligence dissemination requirements (IDRs).

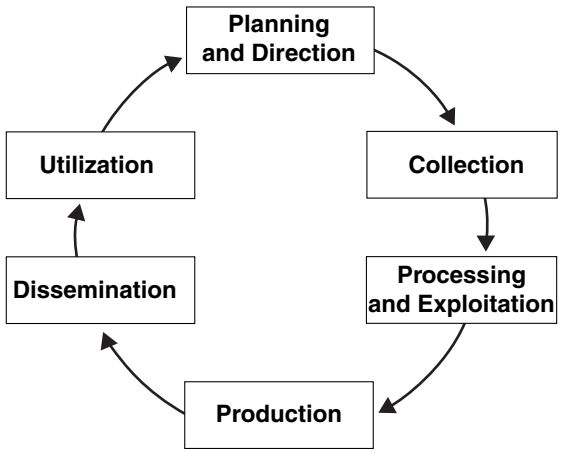

Figure 1-1. The Intelligence Cycle.

- Reviewing on-hand/accessible all-source and IMINT products and databases to see if the needed intelligence is available.
- Planning supporting collection, production, and dissemination efforts for validated requirements.
- Issuing orders and requests to IMINT and all-source agencies.
- Integrating and coordinating intelligence operations with maneuver, fires, communications and information systems (CIS) and combat service support (CSS).
- Supervising to assess the productivity of these agencies to determine if PIRs and IRs are being satisfied, and to rapidly respond to changing battlespace conditions, modifying old or initiating new IMINT orders and operations as appropriate.

The core nodes for all MAGTF intelligence planning are the G-2 plans branch within the MEF G-2 section for intelligence support to future plans; the G-2 operations branch for intelligence support to the current and future operations cells; and the support cell within the IOC established by the intelligence battalion, under the direction of the ISC, for all detailed internal and supporting intelligence and reconnaissance planning.

Effectively identifying IMINT requirements is critical to successful IMINT operations. This is true for several reasons. IMINT operations are only successful if integrated intelligence planning and direction, collection and production management, exploitation, and dissemination functions are effectively accomplished, and especially since generally limited imagery collection and production assets are available. Finally, each and every IMINT requirement requires a well-planned and potentially different technology mix of tools, significant computing power, and technically qualified personnel.

Stating IMINT requirements well is the best way to improve a unit's chances of satisfying their imagery-related intelligence requirement.

Requests for imagery support are submitted via the chain of command using the Joint Tactical Air Reconnaissance/Surveillance (JTAR/S) format shown in appendix C. These will be processed in the IOC by the ISC in coordination with the G-2 operations officer and the G-2 air officer. Requests for imagery must include the following:

Mission

State what must be accomplished, such as finding unlocated enemy forces, distinguishing certain types of tanks, assessing the status of a bridge, etc.

Type of Target

Most MAGTF tactical IMINT requirements will be for point targets of 10 nautical miles or less. Broad area search requirements are taxing in terms of communications bandwidth requirements and man-hours; and should be avoided unless absolutely necessary.

Date Desired

Date desired (DATEDES) is the date-time-group of when the requester requires either the imagery or the IMINT product.

Latest Time Intelligence Is of Value

The latest time intelligence is of value (LTIOV) is the time by which information must be delivered to the requestor in order to provide decision-makers with timely intelligence.

Intelligence Requirements

The requester must identify the specific IRs associated with the imagery/IMINT request. This should also include a statement as to the preferred format/method and quantity for the desired intelligence products.

It is critical that commanders and nonintelligence planners understand what is required of them when stating an IMINT requirement. The following actions are necessary to ensure that IMINT requirements are effectively articulated to intelligence planners, collectors, producers, and disseminators:

- State clearly what is wanted to obtain from the imagery, what specifically it will be used to support, and when you anticipate these actions to occur.

  Example
  I want to be able to clearly identify all obstacles on both approaches to the bridge across river X located at point Y to move tracked and wheeled vehicles across the bridge during the period 14-17 Oct 2000.

- State your DATEDES, which is the date and time you require the imagery or IMINT product be provided to you. This provides IMINT planners with a way of prioritizing their missions, especially when there are limited assets available. This also allows intelligence personnel the option of providing a partial or lower quality product by the DATEDES and using the limited assets for an operation in the execution phase.

  Example
  DATEDES is 1200 14 Oct 00 to support planning and briefing.

- State your LTIOV and what it will support. It is critical that the user carefully considers the date and time submitted as LTIOV, because if IMINT planners cannot meet the LTIOV, the request will be rejected.

  Example
  LTIOV 0500 15 Oct 00, 1 hour prior to the estimated crossing of the line of departure.

  Note: IMINT and intelligence planners must notify supported commanders immediately once it is identified that a LTIOV cannot be met, and that their IMINT requirement will not be supported.

- State the format you desire and at least one acceptable alternative for the IMINT products to be produced. If you have any specific requirements such as specific annotation, state that as well.

  Example
  Request that a finished imagery product be posted in JPEG format on the MEF imagery homepage accessible via either the MAGTF tactical data network (TDN) or SIPRNET. Request standard annotation set. Acceptable alternate format is hard copy print (10 each) in 11x17 inch format.

Collection

Collection is defined as the gathering of intelligence data and information to satisfy identified validated IRs. Within the MAGTF, collection management is a function of the collection management and dissemination (CMD) section that is established during operations within the IOC support cell. For IMINT, the collection phase of the intelligence cycle is complete when the imagery information and data are provided to the processing and production elements in the P&A cell. Imagery collectors available to support the MAGTF may be manned/unmanned, airborne/ground-based, systems or sensors that can operate across the MAGTF areas of interest in day or night, all-weather conditions. The IOC may substitute or supplement organic capabilities by receiving photographic, EO, infrared, radar/multispectral imagery, and IMINT from national, theater, other

Services, host country, embassy team sources, and other multinational allies.

Processing and Exploitation

Processing and exploitation involves the conversion of collected data into information suitable for the production of intelligence. Imagery processing for IMINT purposes refers to the conversion/transformation of exposed film or electronic photographic, EO, infrared, and radar imagery into a form usable for interpretation and analysis. Softcopy imagery is manipulated electronically, internal to a processing/production system. Imagery exploitation by the IIP's imagery analysts is driven by specified PIR and IRs and allows the MAGTF to gain the fullest possible advantage derived from imagery data by identifying specific pieces of equipment, measuring the dimensions of structures found on an image, identifying potential targets, assessing BDA and I&W factors, and otherwise producing IMINT from imagery data.

Production

Production is the activity that converts information into intelligence through the integration, analysis, evaluation, and interpretation of all-source data and the preparation of intelligence products in support of known or anticipated user requirements. IMINT production refers to writing imagery reports; annotating imagery products; creating imagery-derived products; integrating and fusing IMINT into all-source intelligence products; and identifying new or remaining intelligence gaps requiring follow-on intelligence collection or production support. Most IMINT production is accomplished by the IIP, while the P&A cell within the IOC is the principal producer of all-source intelligence products.

Dissemination

Dissemination is the timely conveyance of intelligence to users in a suitable form. The ISC, per the direction and guidance of the AC/S G-2, has principal responsibly for intelligence dissemination within the MEF. The ISC must identify intelligence reporting criteria for both routine and time-sensitive intelligence, determine the forms/formats to be used, and then select the means for delivering intelligence and IMINT products to all supported commanders. For example, intelligence reporting criteria will provide imagery collectors and IMINT producers necessary guidance for when data and products will be delivered to intelligence production or C2 nodes, and when these will be disseminated directly to commanders. Formats selected may be text, graphics or other intelligence products depending upon a variety of factors (available time, capabilities of users, etc.). Further, IMINT operations must be planned and coordinated with supporting MAGTF CIS and courier operations to ensure IMINT products can be delivered or transmitted to users in a timely manner. The core nodes for intelligence dissemination execution are the IOC support cell, and the G-2 section watch within the MEF's current operations center (COC).

Utilization

The commander is responsible for the effective use of intelligence for decisionmaking purposes. Utilization of intelligence for decisionmaking during planning and execution is the ultimate objective of intelligence. The G-2/S-2 facilitates the effective use of intelligence, and thus of IMINT, by supervising the entire intelligence development effort and assisting the commander and staff in understanding intelligence products and their application. Additionally, the utilization phase provides the basis for the continuous functioning of the intelligence and supporting IMINT cycles. It will determine whether IRs have been completely satisfied; those that have not will then require additional intelligence development effort. Finally, as some IRs are satisfied, new ones will be generated. In all cases, utilization provides guidance, feedback, and orders for subsequent intelligence and IMINT operations.

G-2/S-2 Role in the Intelligence Cycle

Figure 1-2 depicts the G-2/S-2 role in the intelligence cycle and highlights that IMINT is one of the capabilities needed to support overall MAGTF intelligence requirements and operations. Since IRs are numerous, complex, and challenging, no single intelligence discipline, source or sensor can provide all of the required data and intelligence in the correct usable format. Some specific data must be processed and all of the seemingly unrelated, individual pieces of information must be evaluated, analyzed, and integrated into a usable, fused, all-source intelligence product that satisfies the commander's operational information needs.

Levels of IMINT

MAGTFs rely on a complementary mix of tactical, joint, theater, other Services, and national imagery and IMINT sources to support planning and operations (see figure 1-3). External imagery support is particularly important in viewing denied areas and assisting the MAGTF in pre-deployment planning and imagery archive development. As the MAGTF moves towards an AO, imagery support is provided by a mix of national, theater, and other Services' assets. Once a MAGTF is within the AO, its organic assets will take on greater importance and provide significant imagery support; however, support is still required from external assets to broaden the commander's view.

National IMINT

National IMINT is extremely valuable for MAGTF purposes, particularly in the early phases of MAGTF operational planning and for viewing denied areas. MAGTF requirements for national IMINT support are submitted via the operational chain of command to the Defense Intelligence Agency (DIA) for ultimate validation,

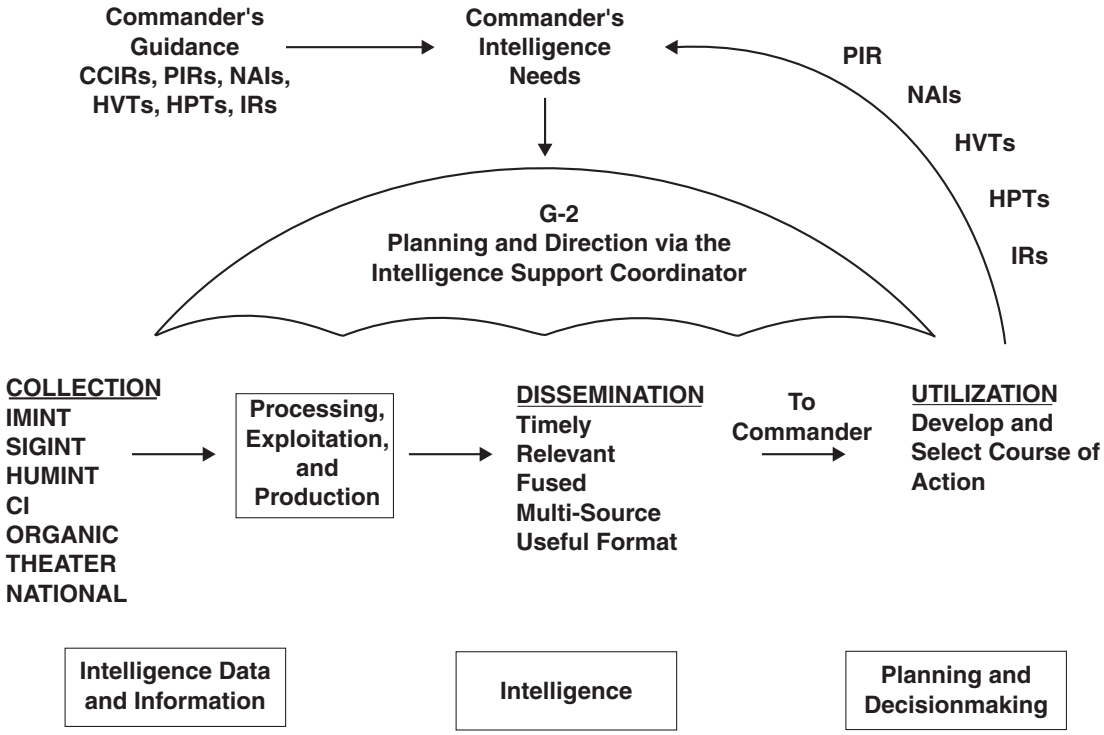

Figure 1-2. G-2/S-2 Role in the Intelligence Cycle.

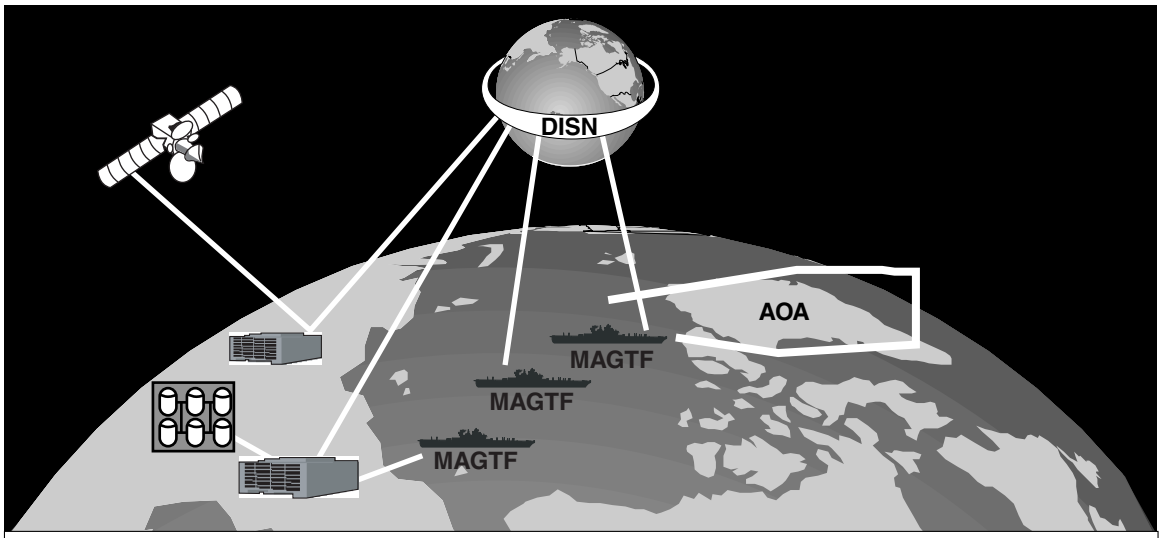

Imagery Support to MAGTF Operations

Pre-deployment
- Load MAGTF IPLs with imagery
- Pre-deployment packages (CD ROM)
- Digital Imagery Database
  - Area Coverage Baseline
  - Baseline Target/Mission Data
  - Geospatial Information
  - Image Maps
  - Mosaics

En route to Area of Operations
- Over-the-Air-Updates (OTAU)
  - Automatic/Profiled Update
  - Target Update Images
  - Special Area Imagery
  - Information and Service Updates

Area of Operations
- (OTAU) and "Pull"
  - Support MAGTF Operations Plan
    - › Landing Zone Analysis
    - › Mission Planning
    - › All-source Visualization and Analysis
  - Support ATO Cycle
    - › Mission Planning
    - › Damage Assessment
  - Support Special Operations

A goal of imagery architecture development is to ensure that imagery products are available to support the MAGTF during all phases of the operation, regardless of geographic location.

Figure 1-3. External Imagery Support Request Chain.

prioritization, and coordination with pertinent elements of the national imagery community (see figure 1-4 on page 1-12). National imagery reconnaissance assets, when available, can be very responsive when at least a 6-hour lead-time exists. The passive nature of most national IMINT collection operations has the advantage of requiring minimal coordination efforts by the MAGTF beyond the initial nomination, validation, and forwarding of the imagery request. Planning time over target (TOT) parameters for most joint force air component commander (JFACC) operations is 72 hours, with aviation combat element (ACE) mission planners generally operating on a 48-hour cycle; Marine expeditionary unit (special operations capable) (MEU[SOC]) ACE and squadron level mission planners typically operate on a cycle of 24 hours or less. (Specific technical and operational capabilities and procedures for most national IMINT resources are classified; refer to either the *Joint Tactical Exploitation of National Systems* manual or theater tactics, techniques, and procedures (TTP) for additional information.)

Theater and Joint Task Force IMINT

Theater combatant commanders play a significant role in imagery support to MAGTFs because of the critical requirement for component interoperability during joint operations. Joint and theater IMINT is provided by the combatant command's organic imagery assets, such as the JSTARS, U-2, and theater UAVs. Combatant commands, through

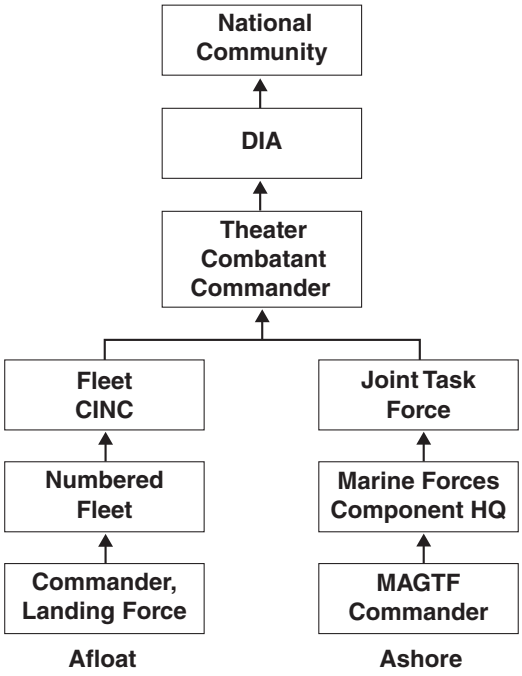

Figure 1-4. External Imagery Support Request Chain.

their joint intelligence centers and joint analysis centers, meet operational IMINIT requirements of component, subordinate intelligence centers, and joint task forces (JTFs).

Tactical IMINT

MAGTF Tactical IMINT

MAGTF tactical IMINT operations include intelligence derived from the collection, processing, exploitation, production, and dissemination of imagery derived from organic collectors (e.g., F/A-18 with ATARS), as well as imagery collected by national or theater collectors but exploited, tailored to MAGTF requirements, and fused into all-source intelligence products, and then disseminated throughout the MAGTF from the IOC. Organic collectors of imagery and imagery-related information, such as UAVs and hand-held cameras, can provide both routine and time-sensitive tactical intelligence. Because MAGTFs are task-organized, their organic capabilities and the degree of external support they require may vary. Forward-deployed MEU(SOC) engaged in forward presence missions normally have only a nucleus of imagery analysts (military occupational specialty [MOS] 0241) providing support within the CE's intelligence section and rely heavily upon external support to fulfill their imagery needs. A MEF with its significant organic imagery capability will need to rely less on external support. In either situation, a MAGTF must plan for a tailored combination of organic, joint, theater, and national imagery that meets the MAGTF's needs for imagery support. Chapters 3 and 4 address current and planned Marine Corps imagery organizations and capabilities available as organic to MAGTFs.

Amphibious Force IMINT

Landing force (LF) and amphibious task force (ATF) intelligence officers collaboratively execute ATF and LF IMINT operations. The organic IMINT capabilities of the ATF and LF are generally limited, necessitating reliance for IMINT support from secondary imagery dissemination from fleet intelligence organizations. A key IMINT resource is the three F-14 Tomcats configured with the TARPS in one of two F-14 Squadrons assigned to each carrier battle group (CVBG). TARPS has two optical sensors (day-only) and one day/night infrared imagery sensor. Navy imagery specialists exploit the film-based TARPS imagery and provide either IMINT reports or actual images to the MAGTF.

CHAPTER 2. ORGANIZATIONS AND RESPONSIBILITIES

A man trusts his ears less than his eyes.

— Herodotus, 484-424 B.C.

Developing the imagery capabilities and executing the IMINT operations to satisfy the wide variety of MAGTF requirements are extremely difficult challenges that require extensive cooperation and coordination among all members of the intelligence community—MAGTF, other Services, joint, and national. This chapter addresses the major roles and responsibilities of various IMINT-related organizations and key personnel within the operating forces and supporting establishment of the Marine Corps, as well as those external to the Corps.

MEF Key Personnel Responsibilities

The Role of the Commander

Command Attention

Intelligence is an inherent and essential responsibility of command. Command attention is critical to military success. The commander must ensure that members of the unit understand the importance placed on intelligence and the requirement to support the intelligence effort. The commander's involvement in the intelligence process encompasses focusing the intelligence effort, participating in the intelligence process, using intelligence in decisionmaking, supporting the intelligence effort, and providing personal evaluation of the intelligence effort.

Intelligence Requirements

The commander focuses intelligence and supporting IMINT efforts through articulation of commander's intent and planning guidance and identification of PIRs. These drive all resulting intelligence collection, production, and dissemination activities.

Resource Allocation

A detailed and well thought out concept of intelligence support, developed in accordance with the commander's intent and concept of operations, will provide appropriate allocation of intelligence capabilities between the MAGTF's main and supporting efforts, and between intelligence support to current operations and the continuous planning efforts for future operations. IMINT resources are limited; trained imagery analysts—as well as IMINT collection, processing, and dissemination assets—compete with nonintelligence missions for their use. Some MAGTF imagery collection assets, such as the F/A-18 ATARS and UAVs, have multimission roles and may be tasked with command and control, targeting, other intelligence, electronic warfare, or other missions in addition to imagery collection. For IMINT operations, therefore, the commander's role in mission prioritization of organic imagery airborne collection and other IMINT assets is particularly important.

Communications and Information Systems Support

The extent to which a MAGTF can request and receive JTF, theater, and national imagery support is a function of the level and effectiveness of its CIS connectivity and throughput capability from the tactical through the theater and national levels. The commander must assess CIS intelligence needs against all competing MAGTF CIS requirements to ensure necessary support is provided.

MEF Command Element G-2 Section and the Intel Bn

Assistant Chief of Staff, G-2

The AC/S G-2 has staff responsibility for intelligence and intelligence operations, to include IMINT (see figures 2-1 and 2-2). The commander relies on the intelligence officer to provide the necessary information on the weather, terrain, and enemy capabilities, status, and intentions.

Through the intelligence operations plan and supporting intelligence and R&S plans, the MEF AC/S G-2 validates and plans IRs; coordinates intelligence priorities; integrates collection, production and dissemination activities; allocates resources; assigns specific intelligence and reconnaissance missions to subordinate elements; and supervises the IMINT and overall intelligence and reconnaissance efforts. Specific all-source and key IMINT responsibilities include:

- Developing and answering outstanding MEF and subordinate units' PIR and IRs by planning, directing, integrating, and supervising organic IMINT and multidiscipline MEF and supporting intelligence operations.
- Preparing appropriate IMINT and other intelligence and reconnaissance plans and orders for the MEF, and reviewing and coordinating the IMINT and all-source intelligence plans of JTFs, theaters, and other organizations.
- Submitting and coordinating all-source and IMINT collection, production, and dissemination requirements beyond the capability of the MEF to satisfy to higher headquarters for JTF, theater or national IMINT systems support.
- Ensuring IMINT and other intelligence information is rapidly processed, analyzed, incorporated (where appropriate in all-source intelligence products), and rapidly disseminated to all MEF and external units requiring these.
- Evaluating JTF, theater, and national IMINT and all-source intelligence support and adjusting stated IRs, if necessary.
- Identifying and correcting deficiencies in IMINT and other intelligence and reconnaissance personnel and equipment resources.
- Incorporating exercise IMINT in training exercises to improve MEF individual, collective, and unit readiness.
- Facilitating understanding and use of IMINT and other intelligence in support of the planning and execution of MEF operations.

G-2 Operations Officer

The G-2 operations officer, under direction of the MEF AC/S G-2, has primary responsibility for intelligence support to the commanding general (CG) and the remainder of the MEF CE in support of current and future operations.

Specific all-source and key IMINT related duties include:

- Coordinating and providing intelligence support (to include key IMINT support) to the CG, the G-3 operations section, and the remaining MEF CE's battlestaff.
- Serving as G-2 representative to the MEF CE crisis action team (CAT).
- Coordinating, providing, and supervising intelligence support to the MEF CE COC, future operations center (FOC), and force fires.
- Planning, directing, and supervising the threat or red cell.
- Providing recommendations on PIR and IR validation, prioritization, and taskings to the AC/S G-2 and the ISC.
- Coordinating and supervising the transition of intelligence planning and operations from G-2 plans to G-2 future operations, and from G-2 future operations to G-2 current operations, to effectively support the MEF's single battle transition process.

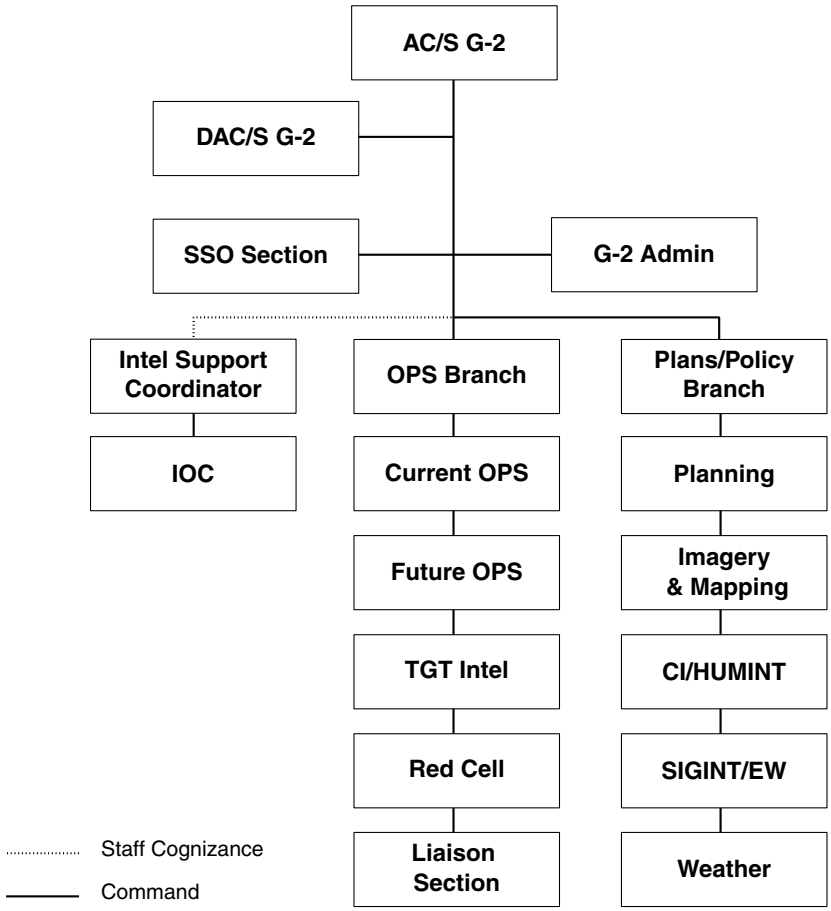

Figure 2-1. MEF G-2 Division Principal Staff Officers and Relationships.

- Planning, directing, and supervising MEF liaison teams to external commands (e.g., the JTF and joint functional components headquarters) and intelligence organizations.
- Coordinating with the ISC and MEF MSCs' G-2 operations officers to ensure unity of effort of MEF intelligence operations.
- Providing intelligence input and other support to MEF warning and fragmentary orders and to operations related reporting (e.g., periodic situation reports).
- Coordinating intelligence training for the MEF G-2 section and providing G-2 oversight for and integration of the MEF intelligence training program.
- Accomplishing other intelligence support and tasks as directed by the AC/S G-2.

G-2 Plans Officer

The G-2 plans officer, under the direction of the MEF AC/S G-2, has primary responsibility for intelligence support to the MEF CE's future plans cell. Specific all-source and key IMINT related duties include:

- Planning the MEF concept of intelligence operations for approval by the AC/S G-2 and subsequent implementation by the ISC based upon the mission, threat, commander's intent, guidance, and concept of operations. This concept of intelligence operations includes a supporting IMINT concept of operations.
- Leading, coordinating, and providing intelligence support to the MEF G-5 future plans section.

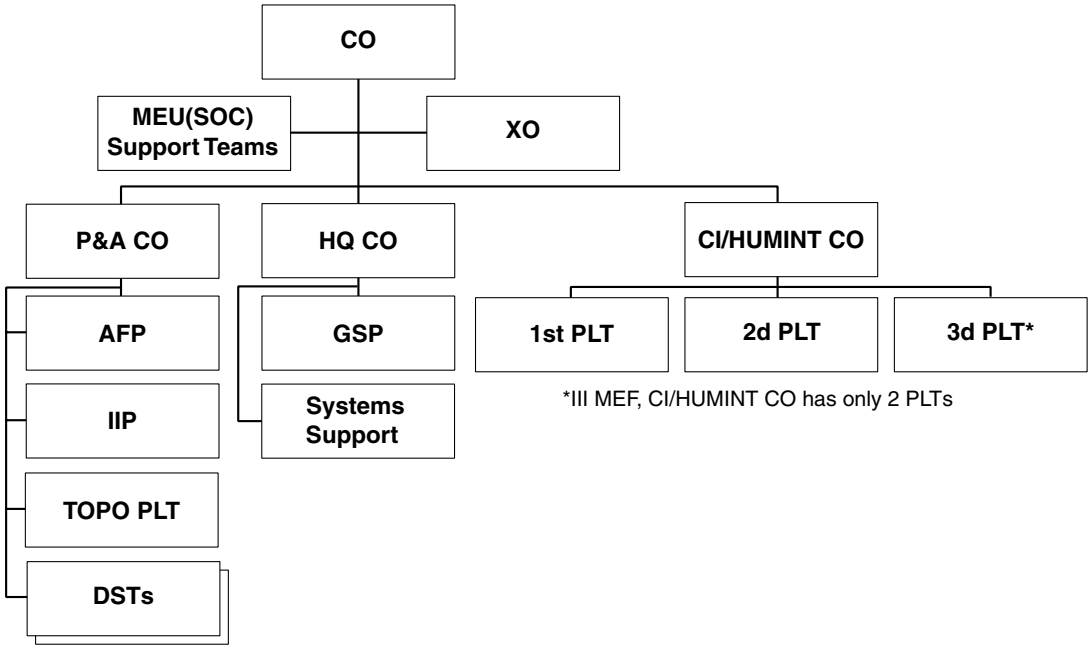

Figure 2-2. Intelligence Battalion.

- Planning and coordinating intelligence support requirements for and the deployment of intelligence elements and resources into the AO.
- Providing recommendations on PIR and IR validation, prioritization, and taskings to the AC/S G-2 and the ISC.
- Coordinating with the ISC, G-2 development of Annex B (Intelligence) and Annex M (Geospatial Information and Services) to MEF operation plans (OPLAN), their supporting appendices (such as the appendix 7, Imagery Intelligence), and all intelligence input to other annexes of OPLANs.
- Keeping the G-2 section, other CE staff sections, intelligence liaison personnel, augmentees, and others apprised of MEF intelligence planning actions and requirements.
- Identifying requirements and providing recommendations to the G-2 operations officer for MEF intelligence liaison teams to external commands (e.g., the JTF or other components' headquarters) and intelligence agencies.
- Coordinating and developing policies for MEF intelligence, CI, and reconnaissance operations.
- Planning, directing, and supervising the MEF G-2's imagery and mapping, CI/HUMINT, SIGINT, and weather sections.
- Accomplishing other intelligence support and tasks as directed by the AC/S G-2/S-2.

Intel Bn Commander/ Intelligence Support Coordinator

The intel bn commander is responsible for planning and directing, collecting, processing, producing and disseminating intelligence, and providing CI support to the MEF, MEF MSCs, subordinate MAGTFs, and other commands as directed.

Garrison. The principal task of the intel bn commander in garrison is to organize, train, and equip detachments that support MAGTFs or other designated commands to execute integrated collection, intelligence analysis, production, and dissemination of intelligence products.

Actual Operations. During operations, the intel bn commander is dual-hatted as the ISC, serving as such under the direct staff cognizance of the MEF AC/S G-2. The intel bn's S-3 section, along with the

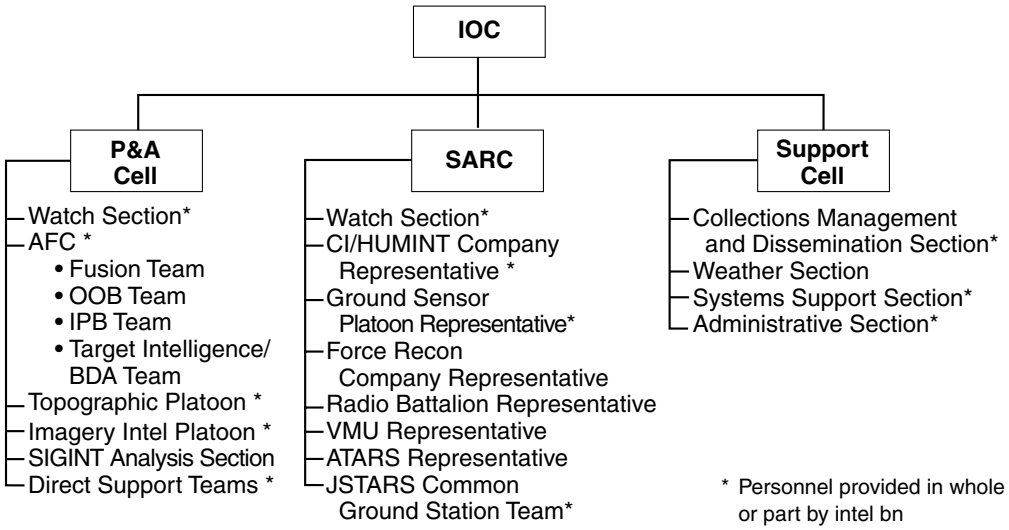

Figure 2-3. Intelligence Operations Center.

operations center element of the MEF G-2, forms the core of the ISC support effort, with planning, direction, and C2 conducted within the IOC's support cell. As the ISC, the commander is responsible to the MEF AC/S G-2 for the overall planning and execution of MEF all-source intelligence operations. Specific all-source and key IMINT responsibilities of the ISC during actual operations include:

- Implementing the concept of intelligence operations (and the supporting IMINT concept of operations) developed by the G-2 plans officer and approved by the AC/S G-2.
- Establishing and supervising operation of the MEF IOC, which includes the support cell, the SARC, and the P&A cell (see figure 2-3). Generally, the IOC will be collocated with the MEF CE's main command post.
- Developing, consolidating, validating, and prioritizing recommended PIR and IRs to support MAGTF planning and operations.
- Planning, developing, integrating, and coordinating MEF intelligence collection, production, and dissemination plans, to include the effective organic and external integration and employment of MAGTF IMINT as well as staff cognizance of MEF SIGINT, CI, HUMINT, GEOINT, ground remote sensors, ground reconnaissance, and tactical air reconnaissance intelligence collections, production, and dissemination operations.
- Developing and completing, with the G-2 plans officer and G-2 operations officer, Annex B (Intelligence) and Annex M (Geospatial Information and Services) to MEF operation orders (OPORDs), their supporting appendices (such as appendix 7, Imagery Intelligence), and all intelligence input to other annexes of OPORDs.
- Planning, developing, integrating, and coordinating intelligence and CI support for the commander's estimate, situation development, indications and warning, force protection, targeting, and combat assessment.
- Managing and fusing the threat (or red) common operational picture (COP)/common tactical picture (CTP) inputs from subordinate units and external commands and intelligence agencies into the MEF CE's threat COP/CTP.
- Providing intelligence support to the MEF CE G-2 section and the MSCs.
- Preparing the intelligence and CI estimates to support G-2 plans.
- Planning, developing, and coordinating intelligence communications and information systems architecture, to include its integration with and support of MEF IMINT and other intelligence and reconnaissance requirements.

- Coordinating and integrating MEF IMINT and all-source intelligence operations with other service components, JTF joint intelligence support element (JISE), theater joint intelligence center (JIC) or joint analysis center (JAC), and national intelligence agencies and operations (e.g., NIMA), to include all aspects of intelligence reachback support.
- Assisting with the evaluation and improvement of MEF IMINT and all-source intelligence operations.
- Accomplishing other intelligence support and tasks as directed by the AC/S G-2.

(See table 2-1 for the principal responsibilities of the AC/S G-2's three principal staff subordinate officers.)

Collection Management/Dissemination Officer

The collection management/dissemination officer (CMDO) is sourced from the intel bn's S-3 section and is a key subordinate to the intel bn commander/ISC during operations. The CMDO is responsible for formulating detailed ICRs and IDRs and tasking and coordinating internal and external operations to satisfy these. The CMDO receives validated PIR and IRs and direction from the ISC, and then plans and manages the best methods to employ organic and supporting collection and dissemination resources through the intelligence collection and dissemination plans (tabs to Appendix 16, Intelligence Operations Plan, to Annex B), which includes all IMINT collection and dissemination activities. The CMDO is also responsible for validating and forwarding national and theater IMINT and other collection requests from the MEF and MSCs typically using appropriate intelligence tools and TTP. The CMDO also is responsible for coordinating intelligence CIS requirements and maintaining awareness of available CIS connectivity throughout the MAGTF and with key external organizations. During operations, the CMDO works within the support cell.

In coordination with the P&A cell officer in charge (OIC), the SARC OIC, G-2 operations officer, IMINT-related unit commanding officers (COs)/OICs, and the MEF G-6, the CMDO is responsible to the ISC for the following IMINT-related tasks. Determining and coordinating the collection effort of PIR/IRs that may be collected via imagery (ATARS, UAVs, national imagery databases) and supporting resources (i.e., force reconnaissance company) Determining of PIR/IRs and preparing requests for intelligence that are beyond organic capabilities and

Table 2-1. AC/S G-2ís Principal Subordinate Staff Officers and Responsibilities.

ISC	G-2 Operations Officer	G-2 Plans Officer
Planning and execution of intelligence operations to support all MEF IRs.	Providing intelligence support to MEF CE battle staff and current operations center agencies.	Providing intelligence support to the plans officer's future planning team for future planning IRs.
Establishing and directing the IOC (P&A cell, SARC, and support cell).	Coordinating intelligence support to higher and adjacent headquarters and agencies.	Recommending IR validation, prioritization, and tasking to AC/S G-2.
Managing IRs (collection, production, and dissemination), validating, prioritizing, and tasking IRs, per AC/S G-2 direction.	Recommending IR validation, prioritization, and tasking to AC/S G-2.	Establishing and directing the G-2 future planning intelligence element.
Exercising C2 of intel bn and staff cognizance over SIGINT, CI, HUMINT, measurement and signature intelligence, IMINT, and air and ground reconnaissance, including staff cognizance of designated G-2 elements.	Establishing and directing intelligence elements and support to the combat operations center, future operations center, target intelligence section, force fires, red cell, and MEF intelligence liaison teams.	Establishing and operating the intelligence section's imagery and mapping, CI, HUMINT, SIGINT, and weather sections (less that under staff cognizance of the ISC).

preparing submissions to higher headquarters and external agencies for support.

- Recommending dissemination priorities, development of intelligence reporting criteria, and advising on and selecting dissemination means.
- Developing and coordinating IMINT and all-source intelligence collection plans, coordinating and integrating these with MEF, other components, JTF, theater, and national intelligence production operations.
- Developing and coordinating IMINT and all-source intelligence dissemination plans and supporting architectures for both voice and data networked communications, and coordinating and integrating these with MEF, other components, JTF, theater, and national intelligence CIS and dissemination operations.
- Monitoring the flow of IMINT throughout the MAGTF and ensuring that it is delivered to intended recipients in a timely fashion and satisfactorily meets their needs.
- Evaluating the effectiveness of MEF and supporting IMINT collection and dissemination operations.

SARC OIC

The SARC OIC is the second immediate subordinate of the ISC and supervises the execution of the integrated organic, attached, and direct support intelligence collection and reconnaissance operations. The SARC OIC is responsible to the ISC for accomplishing the following specific IMINT-related responsibilities.

- Coordinating, monitoring, and maintaining the status of all ongoing imagery collection operations. This includes—
  - Missions, tasked ICRs, and reporting criteria for collection missions.
  - Locations and times for all pertinent fire support control measures.
  - Primary and alternate CIS plans for both routine and time-sensitive requirements, for IMINT collectors as well as between the collectors or the SARC and key MEF CE and MSC C2 nodes, to support ongoing C2 of IMINT collection operations and dissemination of acquired data and intelligence to those needing it via the most expeditious means.
- Conducting detailed IMINT collection planning and coordination with the MSCs and IMINT organizations planners, with emphasis on ensuring understanding of the collection plan and specified intelligence reporting criteria.
- Ensuring other MAGTF C2 nodes (e.g., the current operations center, force fires, etc.) are apprised of ongoing IMINT and other intelligence and reconnaissance operations.
- Receiving routine and time-sensitive IMINT-related reports from deployed collection elements; cross-cueing among intelligence collectors, as appropriate; and the rapid dissemination of IMINT reports to MAGTF C2 nodes and others in accordance with standing PIR/IRs, intelligence reporting criteria and dissemination plan, and the current tactical situation.

Production and Analysis Cell OIC

The P&A cell OIC is the third principal subordinate to the ISC, with primary responsibility for managing and supervising MEF all-source intelligence processing and production efforts, to include all aspects of IMINT production. Key all-source and IMINT-related responsibilities include:

- Planning, directing, and managing operations of the all-source fusion platoon (to include the fusion, OOB, IPB, and target intelligence/BDA teams), the topographic platoon (topo plt), the IIP, the direct support teams (DSTs), and other P&A elements as directed.
- Coordinating and integrating P&A cell operations, estimates and products with the MEF G-2 section's G-2 operations branch and its red cell operations and estimates.
- Maintaining all-source automated intelligence databases, files, workbooks, country studies, and other intelligence studies.

- Planning and maintaining imagery, mapping, and topographic resources and other intelligence references.
- Administering, integrating, operating, and maintaining intelligence processing and production systems, both unclassified general service (GENSER) and sensitive compartmented information (SCI) systems (e.g., the image product library [IPL], joint deployable intelligence support system [JDISS], intelligence analysis system [IAS]).
- Analyzing and fusing IMINT with other intelligence into tailored all-source intelligence products to satisfy all supported commanders' stated or anticipated PIRs and IRs.
- Developing and maintaining current and future intelligence situational, threat, and environmental assessments and target intelligence based upon all-source analysis, interpretation, and integration.
- Managing and fusing the threat COP/CTP inputs from subordinate units and external commands and intelligence agencies into the MEF CE's threat COP/CTP.

IIP Commander/Detachment OIC

The IIP commander is responsible for planning and providing the MEF, and other commands as directed, with imagery and imagery analysis to support operations. Specific tasks include:

- Exploiting and analyzing all-source, multisensor imagery to derive intelligence pertaining to installations, dispositions, strengths, and activities of various conventional and nonconventional forces.
- Employing imagery methods and techniques in the planning and tasking of multisensor platforms, both those organic and external to the MAGTF.
- Conducting imagery exploitation and assisting in imagery management.
- Providing IMINT reports, limited imagery-derived products, and secondary imagery to the MEF and other commanders.
- Conducting liaison with the MCIA for obtaining imagery products in support of MEF intelligence requirements.
- Administering and managing the MEF IPL.

Other Command Element Staff

G-1

The G-1 is responsible for all personnel requirements with regard to the IMINT effort. MEF IMINT requirements may require personnel augmentation to satisfy all requirements. All requests for IMINT personnel augmentation will be developed by the MEF G-2 and provided to the G-1 for either internal sourcing or forwarding to higher headquarters for action (e.g., global sourcing).

G-3

The G-3 is responsible for planning, coordinating, and supervising the tactical employment of units. As such, the movement and operations of IMINT and supporting units must be coordinated by the G-2 with the G-3 for integration in future and current operations planning. Since some imagery supporting units also provide certain nonintelligence capabilities, close coordination between the G-2 and G-3 is necessary for mission prioritization and deconfliction. The G-3 has primary responsibility for the planning and operations of maneuver and fires, and is typically a principal staff user of IMINT, requiring close coordination throughout the planning process to ensure effective IMINT support. Accordingly, G-3 personnel must understand the capabilities of the different IMINT collection systems and exploitation and advantages and limitations of different types of imagery and IMINT products to form realistic expectations of IMINT support, to effectively and efficiently request appropriate support, and to integrate intelligence into operations.

G-4

The G-4 is responsible for the logistic support of attached IMINT units. To ensure the required support is available, arrangements should be developed early in the deployment that meet the particular needs of the deployed IMINT-supported unit. Special attention is drawn to logistics requirements of IMINT units' unique and sometimes sizable equipment (e.g., IIP).

G-5

The G-5 is the principal staff officer responsible for all long-range (future) planning and joint planning matters. Normally, a G-5 is found only at the MEF and Marine Corps forces (MARFOR) levels; at lower MEF echelons future planning is the responsibility of the G-3. The G-5 understanding of imagery/IMINT and the type of support required parallels that of the G-3.

G-6

The G-6 provides for and protects CIS connectivity and operations, both within and external to the MEF. This includes providing the communication paths, network accesses, and frequencies for IMINT organizations organic, attached to and/or supporting the command, which requires significant systems knowledge across IMINT and all-source intelligence CIS.

MEF Major Subordinate Commands' Intelligence Officers

The MSC intelligence officers must understand imagery, IMINT, and their capabilities and uses. Additionally, MSC intelligence officers must be able to articulate in detail all IMINT requests they submit through the chain of command and integrate IMINT support with other command intelligence and reconnaissance operations. Because IMINT resources are generally limited, MSC intelligence officers must recognize that their units' IMINT requirements will compete with all others from throughout the MAGTF. Close coordination among all unit intelligence officers will identify opportunities where small adjustments to IMINT requirements result in satisfying more than one unit's requirement during the same collection and/or production tasks.

Key MSC intelligence officers' IMINT tasks can include:

- Planning and implementing a concept for intelligence support based on the mission, concept of operations, and commander's intent.
- Providing centralized direction for command intelligence operations, to include IMINT elements attached to or placed in direct support of the unit.
- Consolidating, validating, and prioritizing unit IRs and IMINT needs.
- Submitting consolidated requests for external IMINT support to the MEF CE.
- Coordinating operational and CIS links to pertinent supporting external IMINT collection and production elements and operations.
- Providing timely, accurate feedback on the level of unit satisfaction regarding IMINT support received.

National Imagery Organizations

Director of Central Intelligence

The Director of Central Intelligence (DCI) is responsible for the procurement, operation, and management of national imaging systems and programs that support activities from the level of the President and/or the Secretary of Defense to forward deployed MAGTFs.

The DCI's imagery responsibilities cover all phases of the intelligence cycle including direction, collection, processing, production, and dissemination. Responsibility also includes determining current and future requirements, developing imagery-related systems, and establishing security procedures.

To fulfill IMINT-related responsibilities, the DCI has established a network of committees, subcommittees, working groups, and panels composed of representatives from national organizations, Department of Defense (DOD) agencies, and Military Services. The Marine Corps is represented on the DCI's imagery-related committees to ensure Marine Corps support requirements are identified and incorporated at the national level. These national efforts affect both current and future operations. In the near term, this Marine Corps representation maximizes programmatic support for developing new imagery systems and strategies that will provide critical support to MAGTF operations.

National Imagery and Mapping Agency

NIMA is designated a DOD Combat Support Agency. Specified tasks of the NIMA director can include:

- Organizing, directing, and managing NIMA resources.
- Planning, coordinating, and managing the tasking of national IMINT collection operations in support of military operations.
- Providing advisory tasking for theater and tactical IMINT assets, including advising imagery collection elements on collection of imagery to meet national intelligence requirements when collection elements are assigned to or under the operational control of the secretary of a Military Department or the commander of a combatant command, and not allowed by the Secretary of Defense to meet national intelligence requirements.
- Providing and managing imagery and geospatial production and analysis.
- Disseminating imagery, IMINT, and geospatial information by the most efficient, expeditious, and secure means available.
- Developing and making recommendations on national and non-national policy for imagery and geospatial intelligence.
- Developing and coordinating DOD and intelligence community systems and technical standards.

NIMA's Marine Corps Customer Support Team is the focal point for Marine Corps customer support and provides the point of accountability through which requirements are identified and needs are met. Key IMINT tasks include:

- Understanding and coordinating NIMA resources to support Marine Corps needs.
- Assessing, defining, tasking, and coordinating Marine Corps needs into IMINT production actions.
- Providing single point of accountability to the Marine Corps for requirements satisfaction.
- Prioritizing Marine Corps needs into NIMA business plans.
- Managing execution of Marine Corps programs approved for development.
- Measuring Marine Corps satisfaction with NIMA IMINT programs.
- Providing feedback on the status of Marine Corps IMINT production requirements.
- Providing IMINT production expertise to Marine operating forces.

National Reconnaissance Office

The mission of the National Reconnaissance Office (NRO) is to enable US global information superiority. The NRO is responsible for the unique and innovative technology, large-scale systems engineering, development and acquisition, and operation of space reconnaissance systems—to include critical imagery resources—and related intelligence activities needed to support

global information superiority. Its capabilities include support to I&W, monitoring arms control agreements, and support to military operations. The NRO accomplishes its mission through the on-going research and development, acquisition, and operation of spaceborne and airborne intelligence systems. NRO assets and capabilities may be tasked to support MAGTF operations under procedures described in the Joint Tactical Exploitation of National Systems manual.

Defense Intelligence Agency

DIA is a primary coordinator of several departmental imagery programs and activities that contribute to the development and operations of imagery capabilities and IMINT activities. DIA coordinates the Services' and combatant commands' imagery and IMINT requirements; manages centralized DOD collection and production management requirements programs (e.g., requirements for multispectral imagery); coordinates operational and technical interoperability requirements for intelligence dissemination (e.g., by setting data standard formats for secondary imagery dissemination systems); and sponsors and participates in numerous imagery working groups, programs, and panels to address imagery and IMINT capabilities issues. Additionally, DIA coordinates and manages National Intelligence Support Team (NIST) support to joint operations. The NIST is a deployable intelligence team comprised of special intelligence planning, CIS, and analytical support, to include national IMINT support. NIST composition may include elements from DIA, the National Security Agency (NSA), the Central Intelligence Agency (CIA), and NIMA.

Marine Corps Supporting Establishment Imagery Intelligence Organizations

The Commandant of the Marine Corps (CMC) is directly responsible for the internal organization, training, efficiency, and readiness of the Marine Corps; for the operation of its material support system; and for the total performance of the Marine Corps.

Various Marine Corps supporting establishment organizations are staffed with personnel carrying out responsibilities pertaining to IMINT and imagery-related matters. Major organizations are listed below.

Headquarters, U.S. Marine Corps

Intelligence Department
Imagery Plans and Policies Branch

The Marine Corps Director of Intelligence implements those CMC responsibilities as they relate to IMINT and other imagery matters through the Imagery and Geospatial Plans and Policy Branch. Specific imagery and IMINT-related tasks include:

- Developing Marine Corps plans and policies for IMINT.
- Validating Marine Corps requirements for national imagery collection, production, and dissemination of imagery and all-source intelligence products. As the Marine Corps Departmental Requirements Officer (DRO), Imagery and Geospatial Plans and Policy is the final service validation and adjudication authority for all USMC national imagery and IMINT requests submitted through the service (vice operational) chain of command.
- Executing duties as the Marine Corps national imagery community representative on numerous DOD and intelligence community committees, subcommittees, working groups, and panels.
- Advising NIMA on matters pertaining to Marine Corps imagery capabilities and limitations in a joint and multinational environment.
- Coordinating with Marine Corps Combat Development Command (MCCDC) and Marine Corps Systems Command (MARCORSYSCOM) on matters related to IMINT doctrine, organization, training and education, equipment, and support combat capabilities development.

Aviation Department

The Deputy Commandant for Aviation, Headquarters, Marine Corps (HQMC) Aviation Department (AVN), coordinates closely with Navy aviation elements for procurement of manned and unmanned tactical aviation platforms and sensors. In this capacity, critical IMINT programs, such as ATARS and UAV, fall under AVN cognizance.

Marine Corps Combat Development Command

The mission of MCCDC is to develop Marine Corps warfighting concepts and to determine associated required capabilities in the areas of doctrine, organization, training and education, equipment and support facilities to enable the Marine Corps to field combat-ready forces; and participate in and support other major processes of the Combat Development System.

Marine Corps Systems Command

MARCORSYSCOM plans and manages research, development, and acquisition programs through equipment production and fielding for employment by MAGTF forces, to include most imagery and IMINT supporting equipment programs (e.g., SIDS).

Marine Corps Intelligence Activity

The Marine Corps maintains a Service-level intelligence capability within MCIA. MCIA provides tailored intelligence and services that support HQMC; develops Marines Corps doctrine, force structure, force modernization, training and education, acquisition policy and programming; and Marine Corps forces contingency planning and other requirements for intelligence products not satisfied by theater, other Service or national research and analysis capabilities. MCIA focuses on crisis and predeployment support to expeditionary warfare. It complements the efforts of theater, other Services, and national intelligence organizations and provides unique all-source threat, technical, and GEOINT products tailored to Marine Corps operating forces needs. It also coordinates Marine Corps Service imagery collection, production, and dissemination requirements by acting as the Marine Corps Service IMINT collection, production, and dissemination manager, to include taskings of the USMC Reserve's IIP. MCIA is collocated with the National Maritime Intelligence Center (NMIC), Suitland, MD, and at Marine Corps Base, Quantico, VA.

CHAPTER 3. MAGTF IMINT UNITS AND ORGANIZATIONS

Within the Marine Corps, units responsible for the conduct of tactical IMINT are the IIPs, intelligence direct support teams, VMUs, VMFA(AW)s, and ground reconnaissance elements. This chapter describes these units' missions, tasks, organization, and concepts of employment.

Imagery Intelligence Platoon, Intelligence Battalion

Mission

The mission of the IIP is to provide imagery analysis and IMINT support to MAGTFs and other commands as directed.

Tasks

- Exploit and analyze all-source, multisensor imagery to derive intelligence pertaining to installations, dispositions, strengths, and activities of various conventional and nonconventional forces.
- Employ imagery methods and techniques in the planning and tasking of multisensor platforms, organic and external to the MEF or supported MAGTF.
- Conduct exploitation and assist in imagery management.
- Provide IMINT reports, limited imagery-derived products, and secondary imagery to the MEF and other commanders.
- Conduct liaison with the MCIA for the purpose of obtaining imagery products in support of MEF or supported commander's IRs.

Organization

Each MEF has one organic IIP. It is a subordinate unit of the P&A company, intel bn. Each IIP is organized into three elements: a platoon headquarters, two tactical imagery analysis sections, and three imagery analysis teams (see figure 3-1).

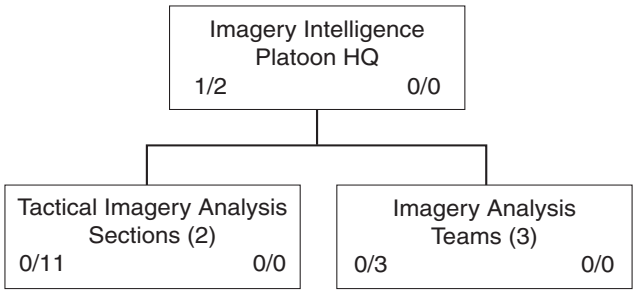

Figure 3-1. IIP Organization.

The 4th Imagery Interpretation Unit (IIU) is in the Reserves. It is organized into a headquarters section, four imagery teams, and a general intelligence support team. It is OPCON to Marine Corps Forces Reserve and ADCON to Marine Air Control Squadron 23. A memorandum of understanding exists that enables the MCIA to task and coordinate 4th IIU imagery exploitation, production, and training support of operating forces requirements.

Command and Control

The IIP is a subordinate unit of the intel bn, with the intel bn commander maintaining full command of its operations. When supporting smaller MAGTFs, the IIP or its detachments will operate under the C2 of either the intel detachment OIC or the supported unit's G-2/S-2.

MEF CE Staff Cognizance

The MEF commander usually exercises C2 over the intel bn elements, to include the IIP, via the MEF intelligence officer. The ISC performs this

function, however, under the staff cognizance of the AC/S G-2.

The ISC in turn exercises C2 of topo plt via the P&A cell OIC. This allows for the centralized direction and effective integration of IIP operations with other MEF IMINT operations and the broader all-source intelligence concept of operations.

Support Relationships

General Support. The IIP will typically operate in general support of the MEF. Under general support, the MEF commander, through the G-2 and the ISC, determines priorities of intelligence collections and production support, locations of IMINT support nodes, and IMINT and all-source intelligence dissemination.

Direct Support and Attached. Depending upon METT-T considerations, the IIP or task-organized imagery analysis detachments from it may be employed in direct support of or attached to a particular unit or MSC of the MEF. In such cases the scope of the supported commander's C2 authority over assigned IIP elements will usually be specified to ensure effective support to operations while allowing the MEF commander to maintain effective C2 of broader intelligence and IMINT operations. Direct support or attachment may consist of dedicated imagery exploitation support, placement of IIP assets with the supported unit, or simply establishing an IMINT node to provide direct dissemination of imagery and IMINT to the supported unit's intelligence section or COC. In the latter relationship, an IIP liaison element should be provided to the supported unit and continuing relationships between IMINT elements and supported units should be established whenever possible.

Concept of Employment

An IIP is capable of supporting one MEF. In support of a Marine Expeditionary Brigade (MEB), MEU(SOC) or other MAGTF, a task-organized imagery analysis detachment may be attached to the MAGTF CE either independently or as part of a larger intel bn detachment. (Some operations may require the activation of X/C-coded billets or global sourcing from other IIPs.)

The reserve 4th IIU conducts peacetime training and production activities in garrison at Buckley Air National Guard Base, Aurora, CO. All IIP production activities support Marine Corps operating forces' OPLAN intelligence requirements. The 4th IIU is capable of providing 24-hour contingency support on-site or providing limited personnel for active duty support.

During MEF operations, the operation of the tactical exploitation group (TEG) will be a focal point of IIP support (see figure 3-2). Each IIP in the operating force will have one TEG. It is packaged in three high mobility, multipurpose wheeled vehicles (HMMWVs). The TEG has the capability to receive, exploit, and produce imagery and IMINT products and reports in support of MAGTF requirements. As such, it will be interoperable with EO, infrared, and radar imagery from ATARS-equipped USMC F/A-18D; the synthetic aperture radar (SAR) system (ASARS-2) aboard the U-2R/U-2S; and with the MCIA, combatant command JICs, and other imagery platforms and organizations. Additionally, the TEG provides the capability to exploit film-based imagery and output from digital cameras and various aircraft heads-up displays/forward-looking infrared (FLIR) and gun camera tapes. Once received and processed/exploited, the imagery is then transmitted over available SIDS device(s) or via other CIS means. Exploited imagery from the TEG may then be hosted on the IPL server located with the IIP, from which MEF users can pull images to support future IRs.

Miscellaneous

Communications and Information Systems

The IIP has sufficient communications resources to support internal and detachment C2 requirements. The IIP will require access to various networks to conduct its operations, to include the SECRET Internet Protocol Router Network (SIPRNET), the

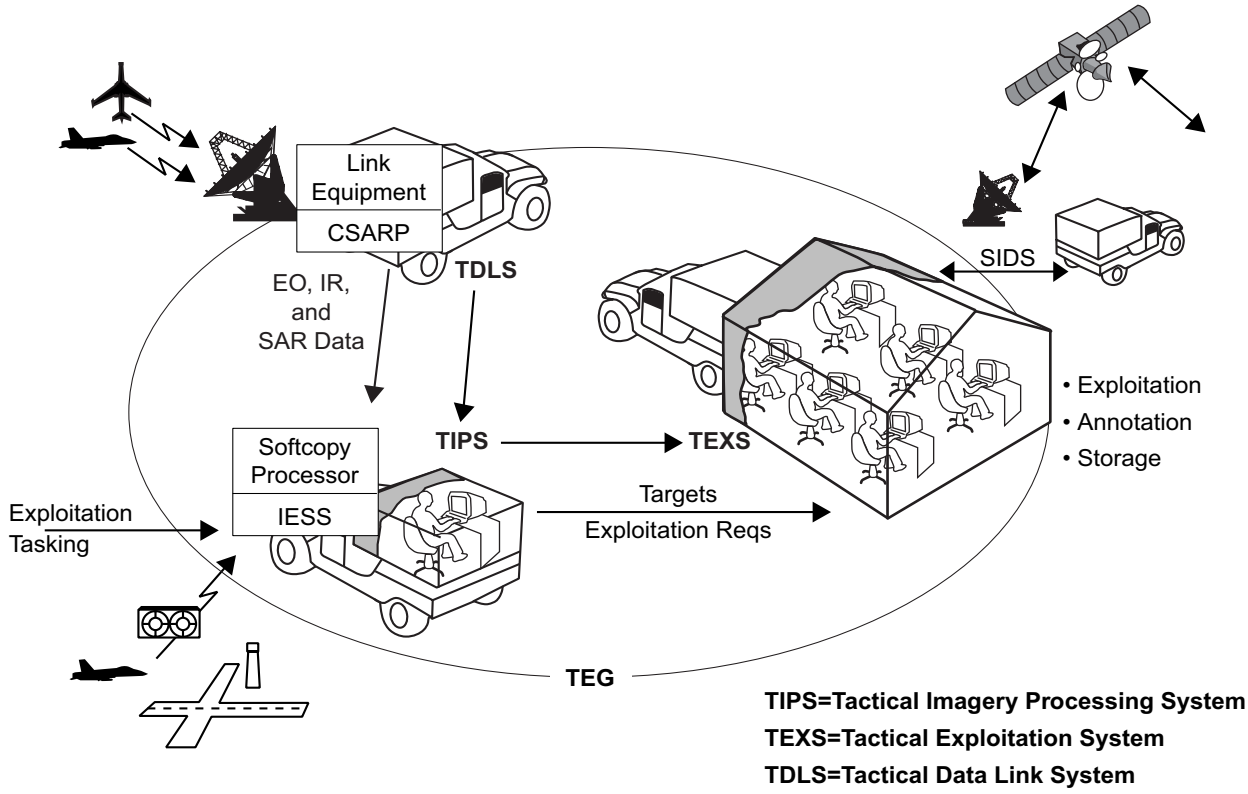

Figure 3-2. Tactical Exploitation Group Concept of Employment.

Joint Worldwide Intelligence Communications System (JWICS), pertinent MEF local area networks (LANs), and designated wide area networks (WANs). There are, however, no communications personnel organic to the IIP or to the intel bn. Communications requirements beyond these must be provided by communications battalion or the supported unit.

The IIP will require at a minimum a dedicated 512 kilobytes per second communications connectivity via SIPRNET to pull imagery from national, theater, and other sources and to disseminate finished IMINT products throughout the MEF and to others as required. This communication requirement is based upon providing a sustained new imagery production rate of 75 images per day for the IIP which is equivalent to their maximum exploitation capability (based upon the current numbers of imagery interpreters and equipment in the IIP's table of organization [T/O] and table of equipment [T/E]) and the baseline projected requirement for the MEF CE and all MSCs to pull from the imagery archive.

Maintenance

The IIP is capable of 1st through 4th echelon maintenance of organic imagery equipment through Marines and civilian contract technicians organic to the platoon. All other maintenance support must be provided by the MEF headquarters group (MHG), combat service support element (CSSE) or supported unit.

Transportation

Intel bn has limited organic vehicular transportation assets to support IIP operations. External transportation support from the MHG, the CSSE, or the supported unit is necessary to displace the entire IIP simultaneously.

Joint Surveillance Target Attack Radar System Common Ground Station

Mission

The primary mission of the JSTARS CGS is to provide the MEF with near-real-time (NRT) access to the moving target indicator (MTI), fixed target indicator (FTI), and SAR data from the Air Force JSTARS collection platform, the E-8C.

Tasks

- Receive, process, manipulate, store, and display MTI, FTI, and SAR data from the JSTARS sensors simultaneously.
- Disseminate JSTARS data to the MEF G-2, other elements of the MEF, and other forces as directed.
- Assist with the planning and direction of JSTARS operations in support of the MEF.
- Provide the capability to communicate, via voice or digital link, with the JSTARS aircraft.

Organization

I, II, and III MEF have one JSTARS CGS and one JSTARS work station that will be used to source all MAGTF JSTARS requirements.

Command and Control

Intel bn commander maintains full command of JSTARS CGS activities.

MEF CE Staff Cognizance

The MEF commander will usually exercise C2 over the intel bn elements, to include the JSTARS CGS, via the MAGTF intelligence officer. The intel bn commander, as the ISC, performs this function under the staff cognizance of the AC/S G-2. This allows for the centralized direction and effective integration of JSTARS operations with other MAGTF IMINT operations and the broader all-source intelligence concept of operations.

Support Relationships

The JSTARS CGS will operate in general support of the MEF.

Concept of Employment

E-8C

Although the JSTARS aircraft is operated and maintained by the Air Force, it is considered a national asset. Its primary mission is the dedicated support of a JTF's joint force land component commander or ground component commander under the overall direction of the joint force commander (JFC).

Properly employed, JSTARS is capable of performing intelligence support, attack support, and battle management functions, along with support to special missions. Its sensor suite provides detection and tracking of moving targets through use of MTI, FTI, and SAR radars. Radar data collected by the E-8C is distributed via an onboard LAN to an encrypted, highly jam-resistant surveillance and control data link (SCDL) for real-time transmission to an unlimited number of CGS.

CGS

The CGS generally will be located within the IOC, near the P&A cell. Once the JSTARS information is received from the E-8C at the CGS, the entire MTI/FTI/SAR image will be disseminated throughout the MEF in accordance with intelligence reporting criteria stipulated by the MAGTF intelligence officer. Under routine conditions this data will be disseminated to the P&A cell for follow-on analysis and fusion with other intelligence data into all-source intelligence products.

Additionally, METT-T factors may require that E-8C data be provided to other elements of the MEF. Under such situations, this data is disseminated to subordinate units via the MEF TDN. The MTI/FTI/SAR image, with its associated data, will be viewed by recipients using common USMC hardware and software suites (potentially down to and including the regimental/group level).

Miscellaneous

Communications and Information Systems

The JSTARS CGS has sufficient communications resources to support internal C2, operations, and intelligence requirements as well as external CIS with the E-8C aircraft. Typically, the JSTARS CGS will require access to the SIPRNET, Nonsecure Internet Protocol Router Network (NIPRNET), possibly JWICS, and pertinent LANs and WANs. CGS team members operate all organic CIS equipment. CIS requirements beyond these must be provided by the MEF communications battalion.

Maintenance

The JSTARS CGS team is capable of 1st through 4th echelon maintenance of organic imagery equipment. All other maintenance support must be provided by the MHG or CSSE.

Transportation

The JSTARS CGS team has sufficient resources to displace all CGS equipment. Additional support will be necessary from the MHG or CSSE to displace CGS personnel simultaneously.

Selected Items of Equipment

CGS. The JSTARS CGS consists of two heavy HMMWVs with integrated shelters and an organic mobile electric power generator. The mission vehicle contains two workstations and associated communications equipment that enable the CGS operators to download, manipulate, and disseminate MTI, FTI, and SAR data received from the JSTARS aircraft. The support vehicle provides transportation for the crew and contains the SCDL antenna that links the CGS to the aircraft.

E-8C. The E-8C is a 707-300 series aircraft that has been extensively remanufactured and modified to achieve like-new performance and a greatly extended service life (see figure 3-3). The most prominent external feature of the modified aircraft is the 26-foot long, canoe-shaped radome located under the forward fuselage. An in-flight refueling system extends the E-8C's 11-hour mission endurance, making missions of 20 hours or more possible. The E-8C's 140-foot long cabin readily accommodates the operator workstations communications suite and associated equipment, with space for rest areas and other crew facilities (see figure 3-4). The standard mission crew complement is 21, but an augmented mission crew of 34 can be easily accommodated.

Figure 3-3. E-8C JSTARS Aircraft.

Figure 3-4. E-8C JSTARS Air Force and Army Crew Onboard Positions.

Direct Support Teams, Production and Analysis Company, Intelligence Battalion

Mission

The mission of DST is to provide enhanced intelligence planning and direction, analytical, production,

and dissemination capabilities to designated supported-unit(s) intelligence sections.

Tasks

- Provide connectivity to the P&A cell for the receipt and dissemination of intelligence to the supported unit.
- Assist the supported unit's intelligence officer in the formulation and management of external intelligence support requirements and other intelligence planning and direction activities.
- Tailor P&A cell and other external-source intelligence products to the needs of the supported unit.
- Perform IPB in support of future operations planning.
- Prepare intelligence products to support detailed mission planning and execution by MEF MSCs or other supported units.
- Augment and enhance the dissemination efforts of the supported unit's intelligence section.
- Act as liaison between the supported unit and the P&A cell.

Organization

There are two DSTs within the P&A company, intel bn. Each team is led by a gunnery sergeant, MOS 0231. Each team also has one imagery analyst (a staff sergeant) to assist with imagery planning and IMINT activities. Other team members include one terrain analyst, two intelligence specialists, and one intelligence clerk. The DST, however, does not have any specialized IMINT equipment.

Command and Control

The DSTs are subordinate units of intel bn, with the intel bn commander maintaining full command of its activities. Under their principal concept of employment, DSTs are under the OPCON of the supported unit commander. The supported commander will exercise OPCON via the unit's intelligence officer. Intelligence taskings to the DSTs will be via the DST team leader in accordance with the supported unit's concept of intelligence operations.

Concept of Employment

The DSTs are primarily employed as organic teams either attached to or placed in direct support of a designated subordinate commander (e.g., the MEF main effort, a MEU/MEB, a special purpose MAGTF). When not employed, DSTs generally augment the P&A cell.

Miscellaneous

Communications and Information Systems

The DSTs have sufficient CIS resources to support internal and detachment C2 and intelligence requirements. They typically will require access to the SIPRNET, NIPRNET, possibly JWICS, and pertinent LANs and WANs. There are no communications personnel organic to the DST. CIS requirements beyond these must be provided by the supported unit.

Maintenance

The DST is capable of 1st echelon maintenance of organic equipment. All higher maintenance is provided by the MHG, CSSE or the supported unit.

Transportation

Intel bn has limited organic vehicular transportation assets to support battalion and DST operations. External transportation support from the MHG, CSSE or the supported unit generally will be necessary to displace the full DST.

Marine Unmanned Aerial Vehicle Squadron

Mission

The VMU operates and maintains a UAV system to provide unmanned aerial reconnaissance support to the MEF or other supported units.

Tasks

- Conduct aerial reconnaissance (to include imagery collection and reporting), surveillance, and target acquisition. This includes performing airborne surveillance of designated target areas, MEF or other areas of interest, and other areas as directed; airborne surveillance for search and rescue and tactical recovery of aircraft and personnel; and reconnaissance of helicopter approach and retirement lanes in supporting vertical assaults.
- Provide real-time target information to the direct air support center and fire support coordination center(s) to facilitate adjusting fire missions and close air support.
- Provide real-time intelligence reporting to the SARC to support MEF IRs and facilitate all-source intelligence operations.
- Provide information to assist adjusting indirect-fire weapons and to support and facilitate direct air support and air interdiction.
- Collect information to support BDA and combat assessment.
- Support rear area security.
- Provide VMU remote receive station (RRS) capability and liaison to designated units.

Organization

The VMU is organic to the Marine aircraft wing (MAW) and is structured to operate as a subordinate unit of one of the Marine air control groups (MACGs). There are two VMUs within the Marine Corps: VMU-1 (MACG-38, 29 Palms, CA) and VMU-2 (MACG-28, Cherry Point, NC). The VMU is organized into various sections that give it the capability to operate and maintain one UAV system and associated support equipment. Regarding IMINT operations, VMU has one Pioneer short-range (SR) system with five UAVs. Key squadron sections include: the S-2 section, including collections, all-source intelligence and five imagery analysts; UAV systems mission commanders and the external and internal UAV operators within the S-3 section; and the Marine aviation logistics squadron augment section that provides intermediate-level aviation maintenance and supply support.

Command and Control

General

VMU is under the command of the MAW CG or, when deployed in support of MAGTFs smaller than a MEF, the ACE commander. The commander exercises C2 via the ACE G-3/S-3 and the Marine air command and control system (see MCWP 3-25, *Control of Aircraft and Missiles*). Air operations (flight taskings, airspace deconfliction, etc.) are planned, coordinated, and controlled by the ACE G-3/S-3 via the tactical air command center (TACC). Intelligence missions, however, are in accordance with the intelligence and reconnaissance mission requirements designated by the MEF or supported unit commander, requiring close coordination between the intel bn's IOC and the MAW's TACC. To assist with UAV mission planning and execution, VMU will generally provide a task-organized team to the IOC, which will typically operate from within the SARC.

Support Relationships

General Support. VMU typically operates in general support of the MEF. Under general support, the MEF commander, through the G-2, determines VMU intelligence priorities and information and intelligence dissemination flow. The AC/S G-2 will exercise staff cognizance of VMU intelligence operations via the ISC.

Direct Support. Depending upon METT-T considerations, specified VMU missions may be in direct support of a particular MEF unit or MSC (e.g., to the Marine division or its main effort). In such cases the scope of the supported commander's C2 authority over VMU missions will usually be specified to ensure effective support to the operations while allowing the MAGTF commander to maintain effective C2 of broader intelligence and IMINT operations. Direct support may entail dedicated C2, planning, and exploitation support to the supported unit via a VMU detachment with a RRS capability.

Concept of Employment

Operational

VMU can support any size MAGTF. Normal employment would be as an integral unit of the MAGTF's ACE in support of MAGTF operations. The squadron is also capable of limited independent operations.

Intelligence

The VMU may conduct limited imagery exploitation or analysis. Generally, UAV imagery is screened by VMU imagery analysts for information of immediate tactical value in accordance with the intelligence collection and reporting criteria stipulated by the ISC or the supported unit's intelligence officer. Imagery tapes are subsequently delivered by VMU to the IIP for further detailed imagery analysis and IMINT and all-source intelligence production. The MAGTF intelligence officer is responsible for subsequent IMINT dissemination (to include secondary imagery dissemination).

Miscellaneous

Communications and Information Systems

Together with CIS resources supporting the Marine air command and control system (MACCS), VMU has sufficient CIS resources to support internal and squadron C2, operations, and intelligence requirements. VMU typically requires access to various networks to conduct its operations, to include SIPRNET and NIPRNET, and to pertinent LANs and WANs.

Maintenance

VMU is capable of conducting 1st and 2d echelon maintenance on assigned ground equipment, including motor transport, engineering, and communications equipment. The force service support group (FSSG) or supporting CSS detachment performs 3d and 4th echelon maintenance on ground equipment. The squadron is also capable of performing organizational maintenance on its aviation equipment. The Marine aviation logistics squadron performs limited, specialized intermediate-level maintenance on squadron aviation equipment.

Equipment

See appendix D for detailed information on VMU equipment and performance characteristics.

Marine All-Weather Fighter Attack Squadron

Mission

The mission of the VMFA(AW) is to attack and destroy surface targets, day or night, under adverse weather conditions; conduct multisensor imagery reconnaissance; provide supporting arms

coordination; and intercept and destroy enemy aircraft under all weather conditions.

Tasks

- Conduct day and night close air support, under all weather conditions.
- Conduct day and night deep air support, under adverse weather conditions, including armed reconnaissance, radar search and attack, air interdiction, and strikes against enemy installations, by using all types of weapons that are compatible with assigned aircraft.
- Conduct multisensor imagery reconnaissance, including prestrike and poststrike target damage assessment and visual reconnaissance.
- Conduct day and night supporting arms coordination, including forward air control, tactical air coordination, and artillery/naval gunfire spotting.
- Intercept and destroy enemy aircraft in conjunction with ground and airborne fighter direction.
- Conduct battlespace illumination and target illumination.
- Conduct armed escort of friendly aircraft.
- Maintain the capability to conduct suppression of enemy air defense operations.

Organization

There are six F/A-18D VMFA(AW)s in the operating forces. Each squadron has 12 reconnaissance-capable aircraft. However, only four can be configured with ATARS at any one time to provide this aerial reconnaissance capability. The VMFA(AW) will normally function as an integral unit. It is structured to operate as a subordinate unit of a MAG.

Command and Control

General

The VMFA(AW)s are under the command of their parent group commander. Overall, OPCON rests with the MAW or ACE commander. The commander exercises C2 via the ACE G-3/S-3 and the MACCS (see MCWP 3-25). Air operations (flight taskings, airspace deconfliction, etc.) are planned, coordinated, and controlled by the ACE G-3/S-3 via the TACC. Intelligence missions, however, are in accordance with the mission requirements designated by the MEF or supported unit commander, requiring close coordination between the intel bn's IOC, the TACC, and supported commanders.

Support Relationships

General Support. VMFA(AW)s typically operates in general support of the MAGTF in accordance with missions contained in the air tasking order (ATO).

Direct Support. Depending upon METT-T considerations, specified VMFA(AW) missions may be in direct support of a particular unit or the ACE or CSSE of the MAGTF. The ATO will identify such missions and pertinent C2 and intelligence operations direction.

Concept of Employment

Operational

The VMFA(AW) will normally be employed as an integral unit of an ACE in support of MAGTF operations.

Intelligence

When equipped with ATARS and tasked to conduct imagery collection missions, the squadron coordinates operations closely with the IOC, the MAW's G-2, the IIP, and others as appropriate. Prior to the fielding of the common data link (CDL), exploitation and processing of ATARS imagery will take place once the aircraft has returned to base and the imagery data tapes are physically downloaded and delivered to the IIP.

Once the CDL is fielded, VMFA(AW) will be capable of NRT downlinking of selected images; the remaining imagery data will be recorded on

tape and downloaded postmission for follow-on delivery to the IIP for imagery exploitation. Figure 3-5 provides an overview of VMFA(AW) ATARS operations.

Miscellaneous

Administrative

The VMFA(AW) is capable of self-administration.

Communications and Information Systems

Together with CIS resources supporting the MACCS, VMFA(AW) has sufficient CIS resources to support internal and squadron C2, operations, and intelligence requirements. VMFA(AW) typically will require access to various networks to conduct its operations, to include SIPRNET, NIPRNET, and pertinent LANs and WANs.

Maintenance

The squadron is capable of conducting 1st echelon maintenance on all assigned equipment. It is also capable of performing organizational maintenance on assigned aircraft and support equipment. Maintenance beyond these capabilities is provided by other ACE and CSSE elements.

Marine Light/Attack Helicopter Squadron

Mission

The HML/A provides combat utility helicopter support, attack helicopter fire support, and fire support coordination during expeditionary operations.

Tasks

- Provide fire support and security for forward and rear area forces.
- Conduct point target/antiarmor operations.
- Conduct antihelicopter operations.
- Provide armed escort, control, and coordination for assault support operations.

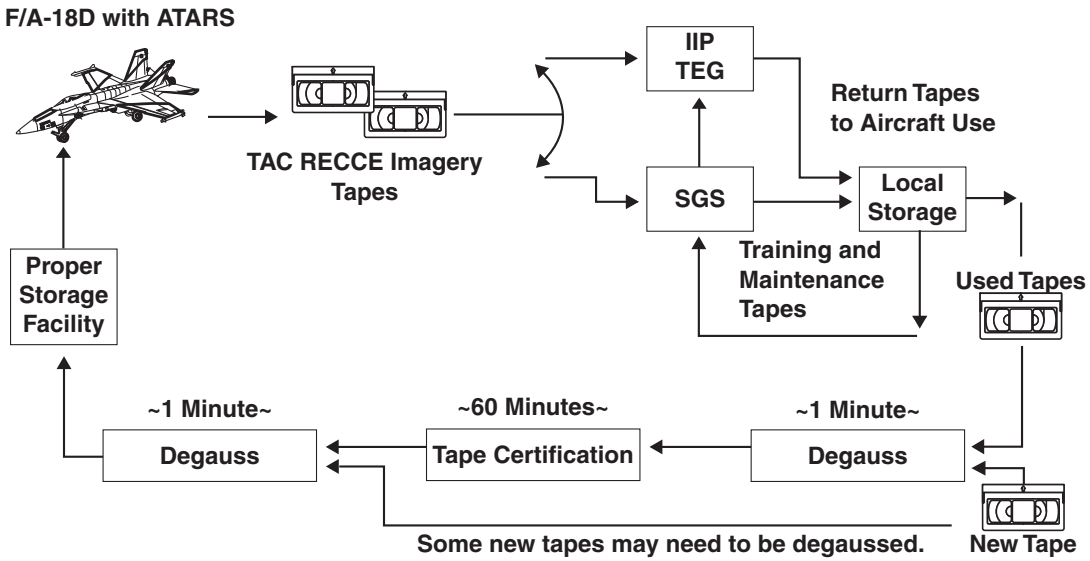

Figure 3-5. F/A-18 ATARS Tactical Reconnaissance Imagery Tape Processing Flow.

- Control, coordinate, and provide terminal ordnance for supporting arms, including close air support, artillery, mortars, and naval gunfire.
- Provide point and limited-area air defense from threat fixed-wing aircraft.
- Conduct armed imagery and visual reconnaissance.
- Augment local search and rescue assets.
- Maintain the capability to operate from amphibious shipping, other floating bases, and austere shore bases as required.
- Maintain the capability to operate at night, in adverse weather conditions, and under instrument flight conditions at extended ranges.
- Perform organizational maintenance on assigned aircraft in all environmental conditions.

Organization

There are six HML/As in the operating forces. Each squadron has 18 AH-1W Super Cobras and 9 UH-1N Huey aircraft, all are reconnaissance capable. An HML/A will normally function as an integral unit, and is structured to operate as a subordinate unit of a MAG.

Command and Control

General

The HML/As may remain under the command of their parent group commander. An HML/A may be attached to a MAGTF where they would operate under the direction of an ACE commander. The commander exercises C2 via the ACE G-3/S-3 and the MACCS (see MCWP 3-25). Air operations (flight taskings, airspace deconfliction, etc.) are planned, coordinated, and controlled by the ACE G-3/S-3 via the TACC. Intelligence missions, however, are in accordance with the intelligence and reconnaissance mission requirements designated by the MEF or supported MAGTF/unit commander and exercised via the staff cognizance of the MAGTF G-2/S-2, requiring close coordination between IOC, the TACC, the squadron, and the supported commanders.

Support Relationships

General Support. HML/As typically operate in general support of the MAGTF in accordance with missions contained in the ATO.

Direct Support. Depending upon METT-T considerations, specified HML/A missions may be in direct support of a particular unit or major subordinate elements of the MAGTF. The ATO will identify such missions and pertinent C2 direction.

Concept of Employment

Operational

HML/A will function either as an integral unit or as a squadron (-) with separate aircraft composite detachments. Each HML/A can support the simultaneous deployment of three detachments consisting of six AH-1W and three UH-1N aircraft per detachment. This concept of organization facilitates dual-site operations, provides for the support of simultaneous contingencies, and allows for the fulfillment of continuous unit deployment program requirements.

Intelligence AH-1W Night Targeting System

The night targeting system (NTS) is an airborne EO system designed to provide the AH-1W crew with the capability to detect, recognize, identify, track, laser range and laser designate targets during day, night, and adverse weather conditions. The NTS is comprised of the following subsystems: FLIR, charged coupled device (CCD) low light level television; direct view optics; AN/ASQ-211 laser designator/rangefinder system and television tracker (TVT); and a super video cassette recorder. The TVT (commonly called the autotracker) and videocassette recorder operate in conjunction with the CCD-TV and FLIR only.

With incorporation of the NTS, the AH-1W Super Cobra provides enhanced air reconnaissance capabilities to include day/night optical and FLIR imagery collection, precision automatic target tracking, laser designation, and video recording. Although the principal purpose of the NTS is to provide Super Cobra gunners the ability to use TOW and Hellfire II missiles and other weapons at full range both at night and through most battlefield obscuration, it is used to collect imagery of a variety of targets during armed reconnaissance missions for follow-on intelligence processing, production, and use.

UH-1N Night Thermal Imaging System

The night thermal imaging system (NTIS) is an airborne EO system designed to provide the UH-1N crew with the capability to detect, recognize, identify, and laser range targets during day, night, and adverse weather conditions, as well as provide a basic pilotage function. The NTIS is comprised of the following subsystems: FLIR, laser rangefinder system, and a videocassette recorder.

Imagery Mission Employment

When AH-1W or UH-1N aircraft is tasked to conduct imagery collection missions, the squadron coordinates operations closely with the MEF's IOC, the ACE G-2/S-2, the IIP and others as appropriate.

Follow-on intelligence processing and exploitation of NTS and NTIS imagery will take place once the aircraft has returned to base and the imagery videotapes are physically downloaded and delivered to the IIP. (Figures 3-6 and 3-7 identify the NTS and NTIS equipment on the AH-1W and UH-1N.)

Miscellaneous

Administrative

The HML/A is capable of self-administration.

Communications and Information Systems

Together with CIS resources supporting the ACE's MACCS, HML/As have sufficient CIS

Figure 3-6. AH-1W with the NTS.

Figure 3-7. UH-1N with the NTIS.

resources to support internal and squadron C2, operations, and intelligence requirements. It typically requires access to various networks to conduct its operations, to include SIPRNET, NIPRNET, and pertinent LANs and WANs.

Maintenance

The squadron is capable of conducting 1st echelon maintenance on all assigned equipment, and capable of performing organizational maintenance on assigned aircraft and support equipment. Maintenance beyond these capabilities is provided by other elements of the ACE and CSSE.

Ground Reconnaissance Units

Mission

The force reconnaissance company and division reconnaissance battalions provide amphibious, deep ground, and ground reconnaissance; surveillance; battlespace shaping; and limited scale raids in support of the Marine division, it's subordinate elements, and the MEF, other MAGTFs or a joint force. IMINT capability fielded to these units is the man packable secondary imagery dissemination system (Manpack SIDS).

Command and Control

Force reconnaissance company and the division reconnaissance battalion are under the command of the supported unit's commanders.

MAGTF CE Staff Cognizance

For intelligence and reconnaissance missions the commander will exercise C2 over ground reconnaissance via the unit's intelligence officer. At the MEF level, the AC/S G-2 will exercise this staff cognizance via the ISC. This allows for the centralized direction and effective integration of ground reconnaissance operations with the broader all-source intelligence concept of operations.

Support Relationships

General Support. Ground reconnaissance units normally operate in general support of the unit.

Direct Support and Attached. Depending upon METT-T considerations, ground reconnaissance units may be employed in direct support of or attached to a particular subordinate unit (e.g., force reconnaissance teams attached to advance force elements for an expeditionary operation; division reconnaissance battalion's platoons or teams

attached to or in direct support of the division's main effort). The scope of the supported commander's C2 authority over designated ground reconnaissance teams will usually be specified to ensure effective support to the operations while allowing the MEF or division commander to maintain effective C2 of broader intelligence and reconnaissance operations.

Manpack SIDS Concept of Employment

Manpack SIDS is a self-contained system comprised of three outstations, a base station, digital cameras, and other specialized devices; communications support must come from other resources. It enables ground reconnaissance units to take pictures of designated targets and then send the images back to the base station over selected communications paths (e.g., high and very high frequency [HF and VHF] single-channel radios and ultra high frequency satellite radios).

The base station then feeds the images into the MAGTF TDN for follow-on dissemination to other MAGTF or other units (figure 3-8 depicts one possible communications architecture for Manpack SIDS). This provides the means to process the images or photocopy sketches even before the team is extracted.

The outstation, with its digital camera component, will be employed by ground reconnaissance teams during missions for imagery acquisition. Imagery collected by the outstation may be stored for subsequent delivery to and analysis by the IIP, or may be electronically transmitted to the base station over organic tactical communications assets for near-real time analysis by the IIP. The base station generally will be employed at the reconnaissance operations center (ROC) collocated with the supported unit's main command echelon for receipt, manipulation, annotation, and subsequent retransmission of imagery collected by the outstation teams.

Depending upon the tasked IRs and the situation, the base station will then disseminate acquired imagery and related information to the P&A cell within the IOC (force reconnaissance team operations), to the division's combat intelligence center for follow-on intelligence analysis, production, and dissemination (division reconnaissance battalion operations) or directly to pertinent unit(s) C2 centers.

Dissemination will generally be in accordance with the intelligence reporting criteria stipulated by the ISC (for force reconnaissance company operations) or the division's intelligence operations officer or supported unit's intelligence officer (for reconnaissance battalion operations) via the MAGTF TDN to the recipient's IAS.

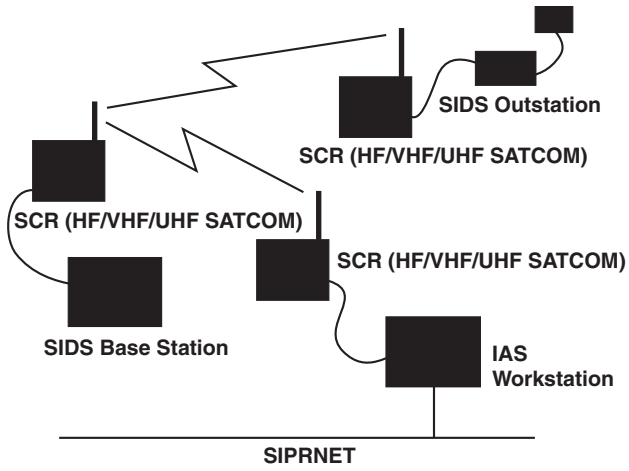

Figure 3-8. Manpack SIDS Communications Connectivity.

Tactical Intelligence Photographic Capability

TACPHOTO is a program related to Manpack SIDS. TACPHOTO provides an organic digital camera collection and processing capability—but without the palmtop processor and base station organic to Manpack SIDS—to a wide range of MAGTF units (see figure 3-9). TACPHOTO allows ground patrols, flight crews and others to collect images per their unit's IRs or external taskings. Upon mission completion and return to base, the acquired images will be downloaded into supporting processing resources for follow-on intelligence production and use. Digitized images can also be further disseminated throughout the MAGTF via the TDN.

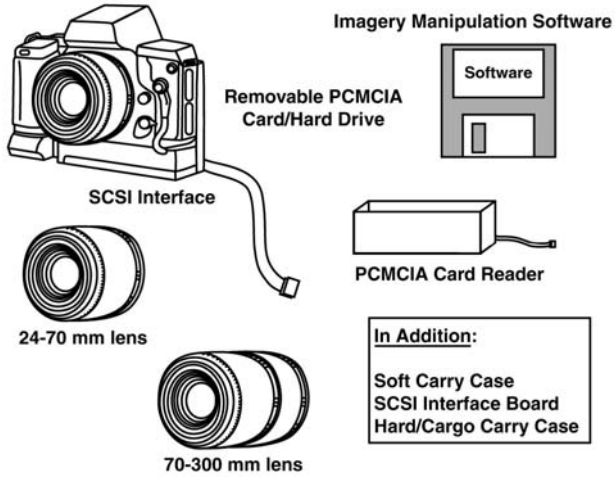

Figure 3-9. Tactical Intelligence Photographic Capability.

CHAPTER 4. IMAGERY INTELLIGENCE SYSTEMS, C2 NODES, COMMUNICATIONS INFORMATION SYSTEMS, AND OTHER SYSTEMS

Communications dominate war; broadly considered, they are the most important single element in strategy, political or military.

—Alfred Thayer Mahan

MAGTFs require significant C2 and CIS support to execute IMINT operations. Imagery systems technological developments have the potential to provide the commander with outstanding imagery support. However, the technical (particularly message and data traffic volumes versus available communications channels bandwidth) and operational needs (i.e., routine versus time-sensitive tailored IMINT support) require detailed planning and coordination of CIS support to conduct effective IMINT operations.

The Marine Corps receives and disseminates imagery as part of the Global Command and Control System (GCCS), via the Defense Information Systems Network (DISN), using Ground Mobile Forces (GMF), digital backbone, tactical radios, and Trojan Spirit II (TS-II). This chapter describes the MAGTF's major current and future IMINT C2 and CIS nodes.

Key to providing the MAGTF commander with IMINT support is understanding the size of imagery data and the capacities of communications pipelines required to transmit this data throughout the MAGTF and to pertinent external organizations. As a general rule, a high capacity (at least T-12) communications pipeline is required for incoming imagery data to the MAGTF, with lesser but still significant capacities required at times for internal MAGTF imagery data dissemination. While most MAGTF requirements can be satisfied via GENSER communications channels (e.g., SIPRNET), the MAGTF must also have SCI communications support (e.g., JWICS) to satisfy some critical requirements.

Basic Imagery Intelligence Communications and Information Systems Requirements

The standard IMINT CIS requirements for a MAGTF operation are—

- **The capability to C2 subordinate units.** Intelligence officers and IMINT element commanders/OICs must be capable of positive C2 of subordinate units and integration of their operations with broader MAGTF and external intelligence and operations C2. Traditionally single-channel radio and record message traffic have been used to support C2 of MAGTF IMINT units. In semistatic situations, secure e-mail or telephone may be the method of choice, while in highly fluid or mobile scenarios, cellular, SATCOM, and VHF and HF radio may be used.
- **The ability to receive collected data and information from the full range of organic and external IMINT organizations.** The CIS architecture must provide connectivity between organic and supporting IMINT elements (such as the VMU, Manpack SIDS capable ground reconnaissance teams), IMINT production and analysis centers (e.g., JTF's NIST, IIP and MCIA), and supported MAGTF operations and intelligence centers. Requirements include the capability to transmit image data files and IMINT reports digitally via fiber-optics, wire, or radio in formats (both voice and data) that are readily usable by imagery and all-source intelligence analysts.

- **The ability to provide intelligence to supported commanders.** IMINT CIS requirements will be influenced by supported commanders' intents, concepts of operations and intelligence, command relationships, and standing PIR and IRs. The CIS architecture must be capable of integrating IMINT element C2 and supporting CIS operations (to include both GENSER and SCI communications) with the primary CIS channels used by supported commanders.
- **The ability to share IMINT products and reports with MAGTF P&A Cell and with IMINT and all-source JTF, other components, theater, and national IMINT and intelligence centers.** The traditional means for providing this capability are MAGTF GENSER secure record and voice communications. While these techniques continue to be used, they are rapidly becoming secondary in importance to the use of JWICS, SIPRNET, and other CIS capabilities that allow participants to access each others' imagery and IMINT products and databases and to immediately pull required data, intelligence, and other IMINT products.

Imagery Intelligence and Key Related Command and Control Nodes

A wide variety of IMINT operations and supporting C2 and CIS may support military operations.

Organization

NIMA

The Director, NIMA, coordinates national CIS support to military and intelligence agencies. NIMA established CIS interoperability standards and data formats for all IMINT operations. Military forces and intelligence agencies use these standards and data formats to support interoperable planning and direction, collection, production, and dissemination of IMINT.

A NIMA Customer Support Response Team (CSRT) may be integrated into a NIST or may be deployed in direct support of a military force. The CSRT will typically contain a deployable imagery/geospatial server known as the Quick Response System (QRS). The QRS is self-contained and generally requires only satellite communications (SATCOM) channel access support from the JTF or other supported unit. The JTF J-2 coordinates SATCOM channel and communications security (COMSEC) support through the JTF J-6. Additionally, depending upon the situation, other CIS and related support that a NIST may require from the supported unit includes information systems technical support and an access controlled secure area (generally within the supported unit's tactical sensitive compartmented information facility [TSCIF]).

During operations, the CSRT QRS provides a MAGTF with a wide range of imagery and geospatial information and services support. In support of garrison operations, a NIMA CSRT provides special training and exercise support to MAGTFs. Also, NIMA may provide MAGTFs temporary specialized equipment to meet unique operational needs or to satisfy critical deficiencies.

National Reconnaissance Office

The NRO has theater-focused customer support teams to provide direct operational support to MAGTFs and other forces. These teams include on-site military/contractor personnel collocated with the combatant and other commands. Basic support includes education on NRO systems and capabilities; training on tasking; and receiving, processing, and analyzing data collected by NRO systems. Equipment and personnel are available to support MAGTF operations during contingencies. NRO support elements are usually self-sufficient, requiring no MAGTF CIS operational support beyond routine communications coordination.

National Intelligence Support Team

All-source national intelligence level IMINT and other intelligence assets may deploy in support

of JTF (and even directly in support of MAGTF) operations as well as providing critical support via reach back and collaborative capabilities. The NIST is the most typical method used. The NIST is a task-organized unit generally consisting of DIA, NSA, CIA, and, as appropriate, NIMA personnel and equipment. Its mission is to provide a tailored, national level all-source intelligence team to deployed commanders (generally at the JTF headquarters level, but support could be provided to other commands) during crisis or contingency operations. Depending upon the supported unit's requirements, a NIST can be task-organized to provide coordination with national intelligence agencies, analytical expertise, I&W, special assessments, targeting support, streamlined and rapid access to national intelligence databases and other products, and assistance facilitating request for intelligence (RFI) management (see figure 4-1).

DIA, through the joint staff J-2, controls the NIST for deployment and administrative purposes (see figure 4-2 on page 4-4 for an overview of a NIST's deployment cycle). During operations a NIST will usually be in direct support of the JFC, who exercises C2 of it via the JTF J-2. Once deployed, the intelligence agencies with representatives on the NIST provide leadership. The basic C2 relationships between the NIST and the JTF (or other supported commands) command relationship are direct support. The NIST will be under the staff cognizance of the JTF J-2, performing intelligence support functions as so designated. The basic NIST concept of operations is to take the J-2's RFIs and collection and production requirements, discuss and deconflict these internally within the NIST to determine which element(s) should take these for action. Each NIST element leader, and as coordinated by the NIST team chief, will conduct liaison with their parent national intelligence organization. Intelligence generated by the NIST is available to the JTF J-2 JISE, the JFC, and other elements of the JTF with the usual restriction based on clearance and programs.

The composition and capabilities of each NIST deployment is unique based on the mission, duration, agencies representation, and capabilities required (see figure 4-3 on page 4-4). A NIST, however, is not a totally self-contained element. It requires logistic and other support from the supported command. Depending upon the situation, support that a NIST requires from the supported

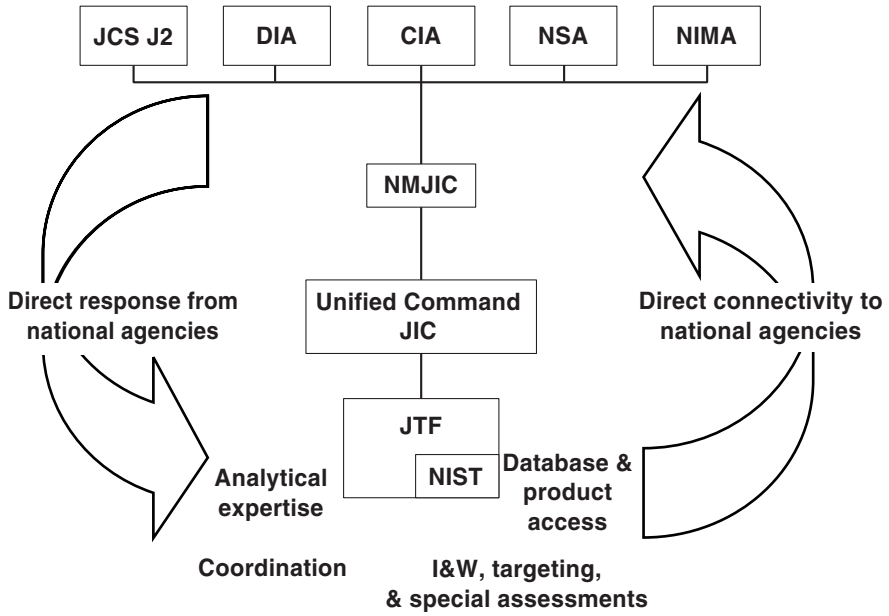

Figure 4-1. NIST Capabilities.

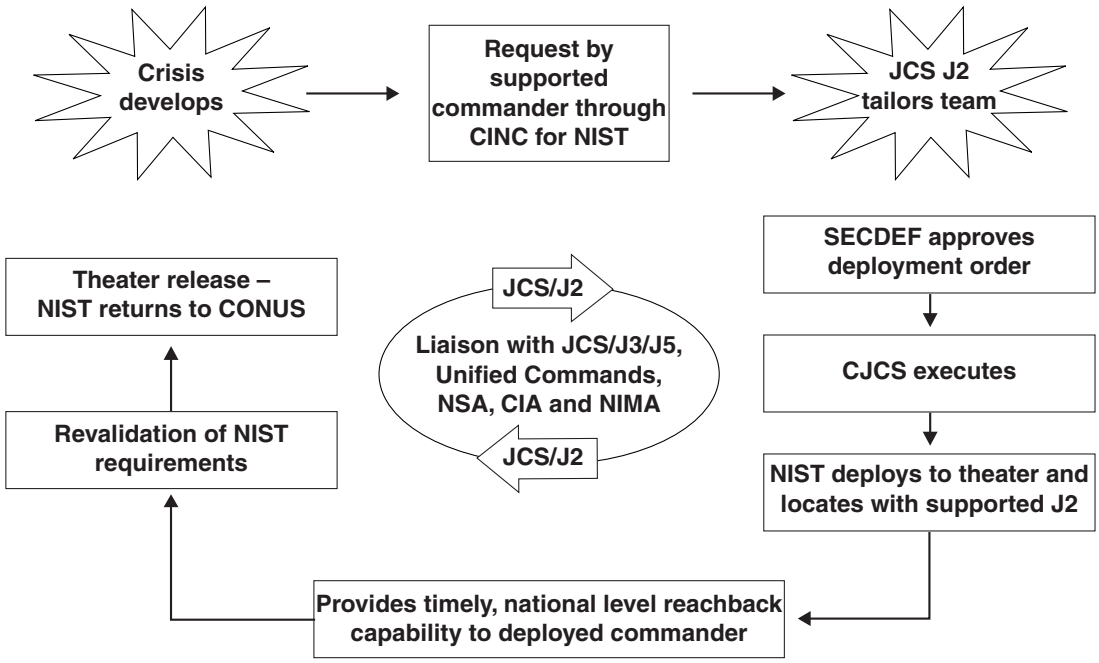

Figure 4-2. NIST Deployment Cycle.

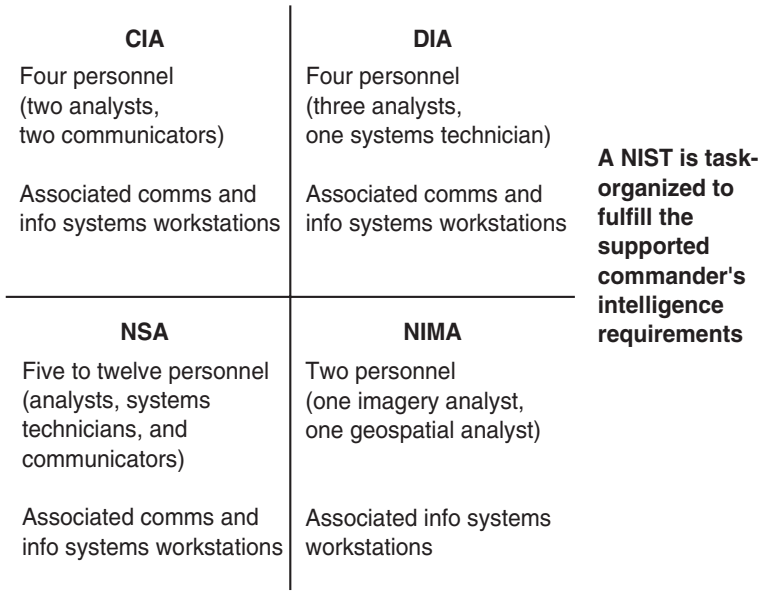

Figure 4-3. Notional Composition of a NIST.

unit includes information systems technical support and an access controlled secure area (generally within the supported unit's TSCIF).

A NIST's organic capabilities generally encompass only intelligence and some unique CIS support. NIST CIS capabilities will be task-organized. A NIST may range from a single agency element's voice connectivity to a fully equipped NIST with JISE and JWICS video teleconferencing (VTC) capabilities (see figure 4-4 for one of a NIST's key sophisticated CIS capabilities). Current methods of operation continue to rely on both agency and supported command-provided communications paths to

Figure 4-4. NIST JWICS Mobile Integrated Communications System.

support deployed NIST elements. The systems that each element is capable of deploying are discussed in greater detail in JP 2-02, *National Intelligence Support to Joint Operations*, appendix C.

Theater

Combatant Commands' Joint Intelligence/ Analysis Centers. The combatant commands' JICs and JAC are the cornerstones for fulfilling the IRs of the geographic combatant commanders and their subordinate commanders. The JICs and JAC are the primary sources from which subordinate JTFs receive intelligence support for their areas of interest, providing finished intelligence products supporting theater mission planning and execution.

Collection. The combatant commander's J-2 retains full collection management authority (i.e., to validate, modify or non-concur) over all intelligence collection requirements against targets within their area of responsibility. Such authority may be delegated to a subordinate JFC. Validated collection requirements, to include imagery collection, that cannot be satisfied by organic JTF means will be submitted to the combatant command's JIC/JAC.

Processing and Exploitation. The JIC/JAC processes and exploits imagery in theater. Downlinked imagery data signals may be transmitted to workstations for either immediate exploitation, stored on tape, sent to digital archives for later use or laid out on film for exploitation.

Production. Combatant commands, services, and defense agency intelligence production centers' production responsibilities are clearly delineated within the DOD Intelligence Production Program (DODIPP). The DODIPP is structured to capitalize on the analytical and production resources of the entire DOD intelligence production community. It supports the efficient use of production resources, prevents duplication of effort, and enhances timely support to user IRs. The Community On-Line Intelligence System for End-Users and Managers (COLISEUM) automates DODIPP procedures for stating and tracking theater IRs and other intelligence production requirements. Results from imagery exploitation and the annotated images may

be incorporated into all-source intelligence products, stand-alone IMINT products or into various IMINT and intelligence databases.

Dissemination. The JDISS, which mainly uses JWICS for connectivity, is the primary intelligence system used by the JIC/JACs for both the receipt and dissemination of imagery and other intelligence products. Using these systems, multimedia intelligence dissemination (e.g., voice, data, imagery, record message, e-mail, graphics, and video) can be supported. Internally, the JIC/JACs use the Imagery Data Exploitation System (IDEX) for manipulation and exploitation of imagery, with JDISS and JWICS used for secondary imagery and other intelligence dissemination. File servers maintained by the JIC/JACs are key components of intelligence support. For imagery, the current capability is provided by the demand driven direct digital dissemination (5D) server, with NIMA's IPL planned as its replacement. These file servers can be accessed using JDISS providing subordinate commands and other users the ability to pull imagery and other intelligence when required. The JICs have access to all of the government-owned, common user networks used by the intelligence community: Automated Digital Network/Defense Message System, (AUTODIN/DMS), Defense Special Security Communications System (DSSCS), NIPRNET, SIPRNET, JWICS, and the Defense Switched Network (DSN). Access to military satellite systems includes the Defense Satellite Communications Systems (DSCS) and the Fleet Satellite Communications System. Commercial satellite access is also available through the International Maritime Satellite System and INTELSAT.

JTF J-2 and the Joint Intelligence Support Element

The JTF J-2 organizational structure and capabilities will be situation and mission dependent as determined by the JFC and the JTF J-2. The JISE is the principal intelligence C2 node within the JTF J-2. The JISE is the focus for JTF intelligence operations, providing the JFC and component commanders with situational awareness and other intelligence support regarding adversary air, space, ground and maritime capabilities and activities.

A NIST provided in support of the JTF headquarters will integrate its operations within the JISE. Key JISE functions and capabilities include collection management support, OOB analysis, identification of threat centers of gravity and critical vulnerabilities, and intelligence support to targeting and force protection.

All IMINT collection, production, and dissemination activities will be conducted within the JISE. Once IMINT products and support have been provided to the JTF and its components, updates will be accomplished by the JISE using push/pull dissemination techniques. Intelligence CIS based on the JDISS/JWICS functionality provide the JTF with the ability to query theater and national IMINT servers and databases for the most current intelligence.

Collection

The JTF J-2 collection manager will plan, coordinate, and use direct imagery collection operations in support of the JTF. As shown in figure 4-5, theater and JTF imagery collection assets include the U-2, JSTARS, theater UAVs, and other-Service assets such as the Navy's F-14/TARPS and the Air Force's RF-16. MAGTF interfaces with these collection assets are depicted by the lines in figure 4-5. Communication support planning provides connectivity from these major nodes into the TEG and MAGTF TDN.

Production

IMINT production requirements are managed by the JISE in accordance with the JFC's PIR and other validated IRs.

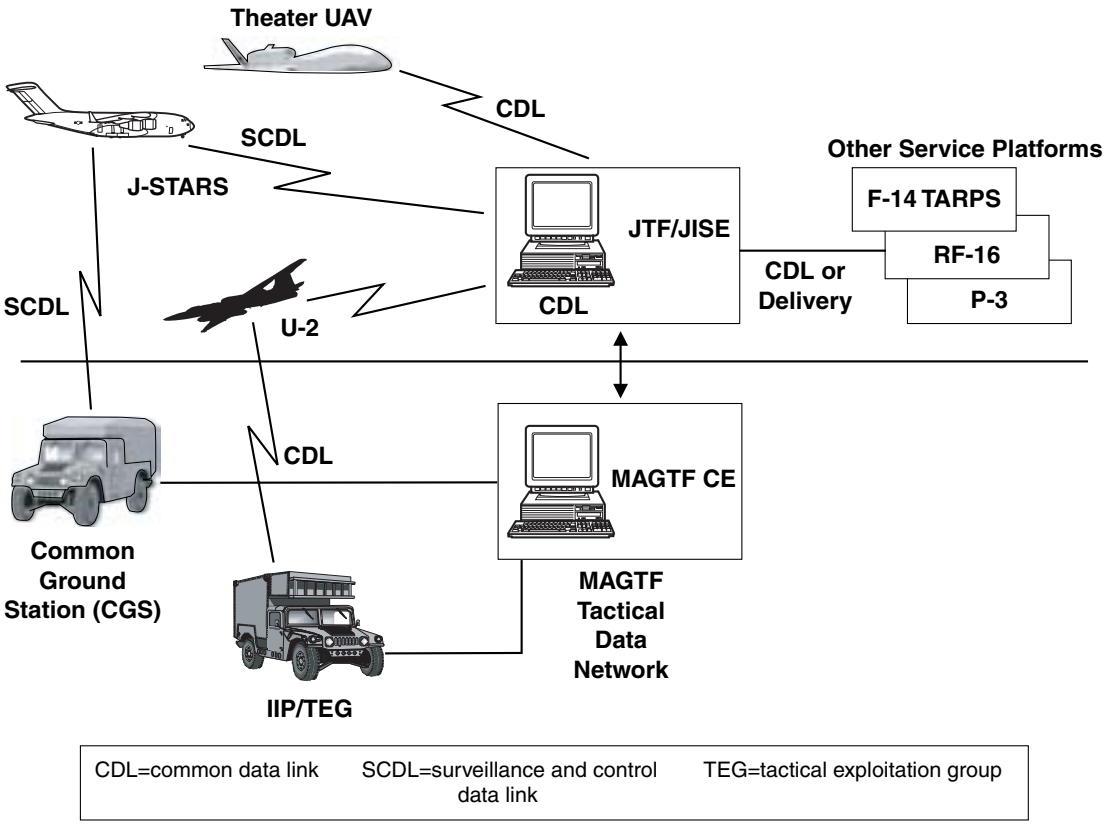

Figure 4-5. Theater/JTF Imagery Collection.

Dissemination

Once basic and current intelligence and imagery have been provided to a deploying JTF and its components, updates will be accomplished using push/pull dissemination techniques. Intelligence CIS based on the JDISS/JWICS functions provide the JTF with the ability to query theater and national IMINT servers and databases for the most current intelligence.

Amphibious Forces

LFs, when afloat, use the ATF's imagery dissemination backbone, such as Challenge Athena and Joint Services Imagery Processing System (JSIPS)-Naval, and continue to receive imagery support from the Navy once ashore, via doctrinal communications.

Intelligence Center

During amphibious operations, the intelligence sections of the ATF and the LF will generally integrate their operations. The principal intelligence C2 node afloat is the intelligence center located aboard the AF flagship. The intelligence center is composed of designated shipboard spaces with installed CIS systems that support the intelligence operations of the ATF and LF while reducing duplicative functions and producing more comprehensive and timely intelligence for the naval task force. Standard CIS connectivity is available (JWICS, SIPRNET, NIPRNET, AUTODIN, DSN). Access is provided via the flagship's GENSER communication center and the special intelligence communications center within the intelligence center's ship's signals exploitation space.

CVBGs/TARPS Squadrons

TARPS support to MAGTF operations requires no unique CIS support. Most often, TARPS imagery is delivered to the intelligence center located aboard the AF flagship via courier. Processed TARPS imagery may be digitized and disseminated to the ATF and LF via JDISS, JWICS or the Global Command and Control System-Maritime.

MEF Command Element

Combat Intelligence Center

The CIC and its subordinate elements are the principal MAGTF intelligence C2 node providing the facilities and infrastructure for the centralized direction for the MEF's comprehensive intelligence, CI, and reconnaissance operations. Since the CIC must effectively support the entire MEF, it must remain responsive to the requirements of all elements of the MAGTF. Supporting this objective, the CIC integrates and supports both MEF G-2 section and intel bn operations. While integrated, the organizational approach differs for each of these. The CIC is the overarching intelligence operations center established within the MEF main command post. It encompasses the primary functions of the MEF intelligence section and intel bn. The CIC includes the subelements listed in table 4-1.

Table 4-1. MEF CE CIC and Intel Bnís IOC Key Elements.

Element	Responsibilities
G-2 Plans	Serves as the G-2 section's main element for coordinating and providing intelligence support to the MEF CE future plans team and leadership and direction of the G-2 section's imagery and mapping, SIGINT, and weather sections.
G-2 Operations	Serves as the G-2 section's main element for coordinating and providing intelligence support to the MEF CG, battle staff, and current operations center elements; target intelligence support to the force fires and future operations; G-2 section intelligence requirements management activities; red cell support; and MEF intelligence liaison with external commands and organizations.
IOC	Serves as the principal MEF intelligence operations and C2 center that is established by intel bn; performs intelligence requirements management, staff cognizance of ongoing organic and supporting collection operations, intelligence production and analysis, and intelligence dissemination.
• Support Cell	Serves as primary element for conducting MEF-wide intelligence requirements management, weather support, collections and dissemination planning and direction, and intelligence staff cognizance of MEF organic and supporting intelligence and reconnaissance operations.
• P&A Cell	Serves as the primary production and analysis element of the MEF; processes and produces all-source intelligence products in response to requirements of the MEF; serves as the principal IMINT and GEOINT production element of the MEF.
• SARC	Serves as the primary element for the supervision of MEF collection operations; directs, coordinates, and monitors intelligence collection operations conducted by organic, attached, and direct support collection assets.
CI/HUMINT Company Command Post	Serves as the primary element for conducting CI/HUMINT planning and direction, C2, and coordination of MEF CI/HUMINT operations with external CI/HUMINT organizations.
Operations Control and Analysis Center	Serves as the main node for the C2 of radio battalion SIGINT operations and the overall coordination of MEF SIGINT operations; processes, analyzes, produces, and disseminates SIGINT-derived information; and directs the ground-based electronic warfare activities of the radio battalion.
Reconnaissance Operations Center	Serves as the main node for the C2 of force reconnaissance company's operations and the overall coordination of MEF ground reconnaissance operations; processes, analyzes, produces, and disseminates ground reconnaissance-derived information in support of MEF intelligence requirements.

The key G-2 nodes are organized to effectively align and support the MEF CE's staff cross-functional cellular staff organization (see figure 4-6) and concept of operations. The G-2 plans branch provides intelligence support to the MEF CE's future plans cell efforts. The G-2 operations branch provides intelligence support to the MEF CE's COC, FOC, force fires center and directs and manages the G-2's red cell and the MEF's external intelligence liaison teams.

CIC facilities, CIS, and other support must allow the AC/S G-2 and G-2 section to perform the following major tasks:

- Developing and answering outstanding MEF and subordinate units' PIR and IRs by planning, directing, integrating, and supervising MEF organic and supporting intelligence, CI, and reconnaissance operations.

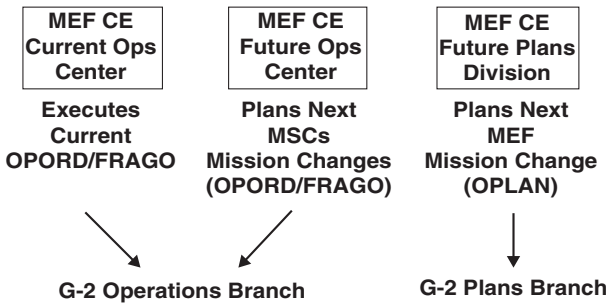

Figure 4-6. MEF CE Cross-Functional Cellular Organization and Intelligence Support.

- Planning the MEF concept of intelligence operations for approval by the AC/S G-2 and subsequent implementation by the ISC based upon the mission, threat, commander's intent, guidance, and concept of operations.
- Recommending CI and force protection measures and countermeasures.
- Preparing appropriate intelligence plans and orders for the MEF, to include reviewing, coordinating, and integrating the intelligence plans of JTFs, combatant commands and other organizations.
- Coordinating, providing, and facilitating the use of intelligence to the MEF CG, the battlestaff, the future plans cells, the FOC, the COC, and the force fires center.
- Planning, directing, and supervising MEF liaison teams to external commands (e.g., the JTF and joint functional components headquarters) and intelligence organizations.
- Coordinating and supervising the transition of intelligence planning and operations from G-2 plans to G-2 future operations, and from G-2 future operations to G-2 current operations, to effectively support the MEF's single battle transition process.

Intelligence Operations Center

The IOC is the other principal MEF CE intelligence node. The key subordinate elements within the IOC and their typical composition are the support cell, the SARC, and the P&A cell (see figure 4-7). It provides

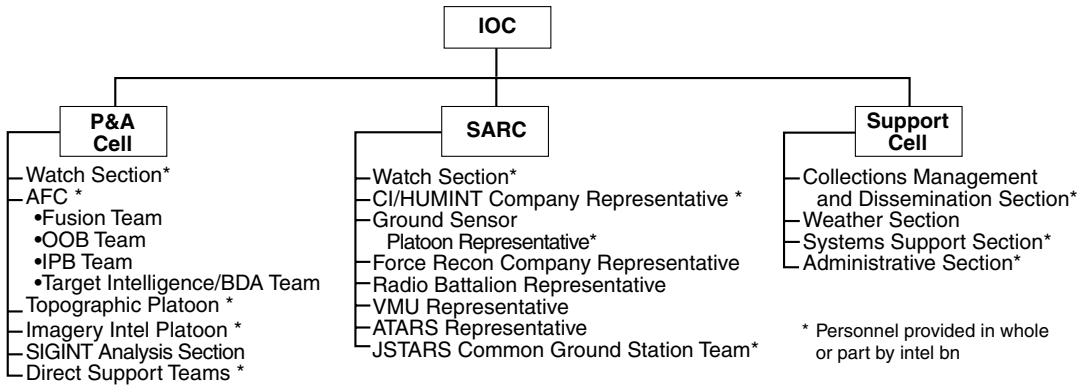

Figure 4-7. Intelligence Operations Center Elements and Composition.

the facilities, CIS, and other support to allow the ISC and intel bn to perform the following tasks:

- Provide centralized direction for MEF intelligence operations under the staff cognizance of the AC/S G-2. The IOC is the core for this task, with key assistance from the G-2 plans and G-2 operations elements.
- Consistent with the commander's priorities, consolidate, validate, and prioritize IRs of the entire force. The key element providing this is the CMD section within the IOC's support cell. Intelligence specialists from all disciplines, to include IMINT, generally are organic to this section.
- Plan, develop, and direct the MEF collection, production, and dissemination plans and operations. The key elements providing for this are the CMD section within the IOC's support cell and the P&A cell.
- Submit consolidated requests for external intelligence support through the Marine component headquarters to appropriate agencies. The key element providing this is the CMD section within the IOC's support cell, assisted by the P&A cell and the G-2 operations branch.
- Allow ISC to exercise, per AC/S G-2 cognizance, principal staff cognizance of MEF organic and supporting intelligence, CI and reconnaissance operations, to include SIGINT, IMINT, HUMINT, GEOINT, CI, measurement and signature intelligence (MASINT), ground reconnaissance, and aerial reconnaissance operations.
- Coordinate and manage the employment of MEF organic collection assets through the IOC's SARC. Within the SARC will be representatives from most organic and supporting intelligence and reconnaissance units to provide C2 and reporting of ongoing intelligence operations.
- Maintain a consolidated, all-source intelligence production center in the P&A cell. Intelligence specialists from all intelligence disciplines generally are organic to the P&A cell. The other node with significant intelligence production involvement is the radio battalion's OCAC.
- Link the MEF CE to national, theater, joint, other-Service, and multinational intelligence assets and operations. All intel bn and G-2 section nodes have common and unique capabilities to perform critical tasks within the function. In addition to MEF CE common communications pathways provided by the communications battalion, the IOC generally will also have unique intelligence communications capability, such as TS II.

CIS Support

CIS support to CIC and IOC operations vary from operation to operation based upon METT-T. Generally all nodes will have access to IAS and JDISS (each with COLISEUM and other specialized applications) and connectivity with the full range of communications (JWICS, SIPRNET, NIPRNET, DSN, defense message system, voice, video-teleconferencing, etc.) via either MEF CE common communications or unique intel bn CIS capabilities. Examples of unique intelligence CIS capabilities are those integral to the VMU squadron RRS, the radio battalion technical control and analysis center and the AN/MSC-63A special security communications central, the ground sensor platoon's tactical remote sensor system, the IIP's TEG, the Marine tactical electronic warfare squadron's tactical electronic reconnaissance processing and evaluation system, the CI/HUMINT automated tool set, Manpack SIDS, TS-II, and the JSTARS CGS. See figure 4-8 for a notional depiction of an overarching MEF intelligence CIS architecture.

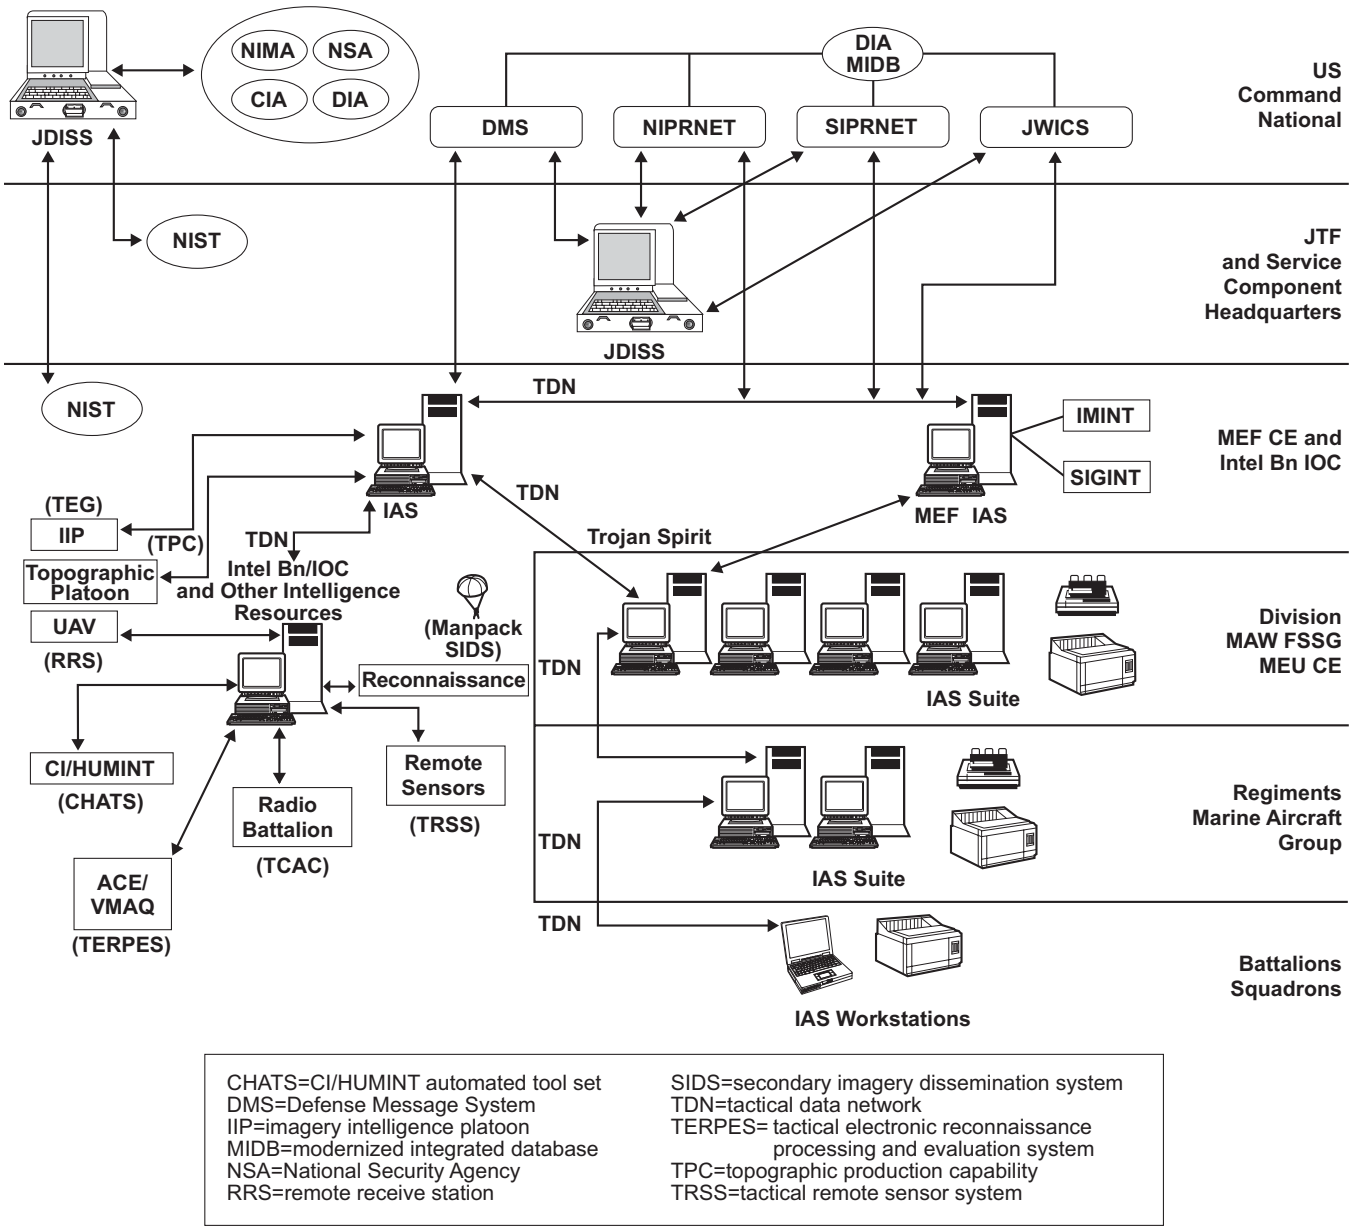

Figure 4-8. Notional MEF Intelligence Communications and Information Systems Architecture.

Overall MEF Intelligence C2 Relationships

The MEF G-2 section and intel bn's overall C2 relationships and resulting all-source intelligence support flow throughout the MEF are indicated in figure 4-9 on page 4-12.

CIC/IOC Operations and IMINT

IMINT activities will be integral to many CIC/IOC operations.

Key activities include:

Collection. The CMD section, headquarters, intel bn, provides the core for MEF CIC collection operations. During operations the CMD section is located within the IOC's support cell. Intelligence specialists from all disciplines, to include IMINT, are organic to this section. Key CIS resources required included IAS (with COLISEUM and other specialized applications) and access to the full range of communications: JWICS, SIPRNET, NIPRNET, DSN, etc.

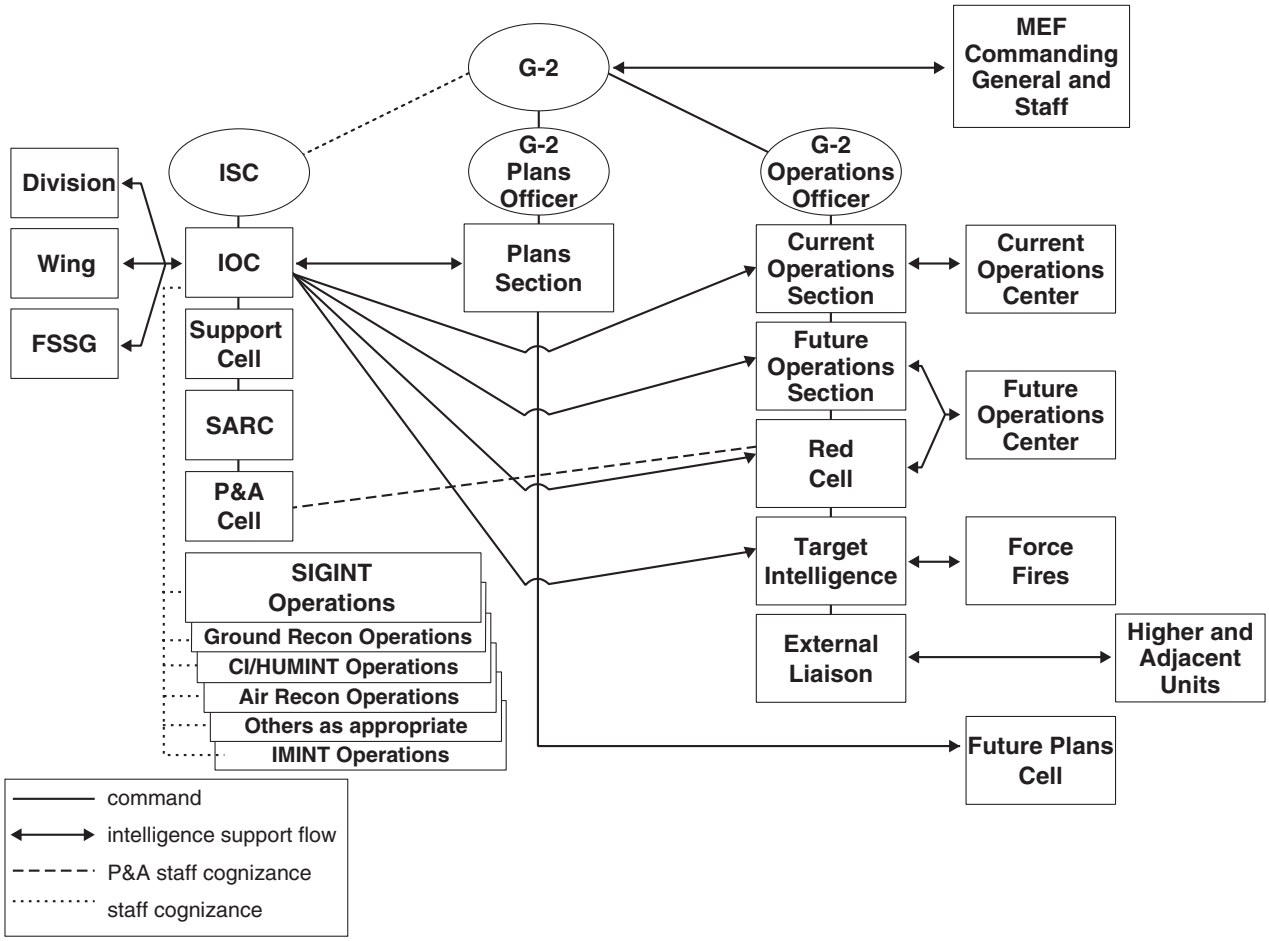

Figure 4-9. MEF Intelligence C2 Relationships and Intelligence Support Flow.

The SARC, another key element within the IOC, provides the other key component of collection operations. Within the SARC will be representatives from most organic and supporting intelligence and reconnaissance units to provide C2 and reporting of ongoing intelligence operations. Regarding IMINT, these representatives will include a UAV squadron element with supporting CIS resources to monitor ongoing UAV operations and report time-sensitive intelligence.

Production. The P&A cell, intel bn, provides the core for MEF intelligence production operations. Similar to collection, intelligence specialists from all intelligence disciplines are organic to the P&A cell. Key CIS resources required included IAS and JDISS, with access to the full range of communications (JWICS, SIPRNET, NIPRNET, DSN, etc.). The IIP and intel bn generally will be integrated into P&A cell operations to efficiently support both IMINT and all-source production operations.

Dissemination. The CMD section, headquarters, intel bn, provides the core C2 for MEF intelligence dissemination operations. Key CIS resources required included IAS and JDISS, with access to the full range of communications (JWICS, SIPRNET, NIPRNET, DSN, etc.) for external dissemination; and IAS via the TDN and other MEF communications resources for internal dissemination.

The MEF CE will exploit all of the external capabilities discussed earlier to satisfy its IRs, with heavy reliance on the MCIA for national imagery support and the JIC/JAC for theater and national support. National imagery and related

products are received over dedicated terrestrial links that terminate at the MCIA's JSIPS National Dissemination Element (DE); standard communications connectivity from the deployed MEF to the MCIA via the DISN are normally provided by satellite communications. Currently, these links are predominantly super high frequency (X-Band) military SATCOM using GMF terminals. In the future, more C-Band and Ku-Band commercial SATCOM will be employed, using mobile Tri-Band SATCOM terminals. The limited capacity of these links to DISN remains a significant choke point for deployed MAGTFs. Efficient use of these links is critical to higher effective traffic throughput.

In addition to the MAGTF TDN and other common user communications capabilities, certain imagery units have specialized capabilities to support IMINT dissemination. The UAV squadron's RRS, attached to MEF MSEs (e.g., the MEF main effort), provides direct, time-sensitive UAV support.

Within the MEF, the IAS is the principal information system resource to support secondary imagery and other IMINT product dissemination. IAS will be available at all command echelons down to the maneuver battalion/squadron levels.

Communications connectivity between the MEF CE and its MSE headquarters are predominantly provided by SATCOM, supplemented where practical with terrestrial line-of-sight and troposcatter multi-channel radio systems. Connectivity to the regiment/group level is principally via the TDN (with current capabilities of between 16 and 32 kilobytes per second [kbps]) and various multichannel radio resources. Finally, communications connectivity below the regiment/group command echelon depends principally on single channel radio primarily designed for voice traffic, with limited range and limited data capacities (1.2 kbps to 16 kbps). Although these units possess tactical data systems, their ability to exchange data traffic is currently limited due to the far less available bandwidth connectivity with the MAGTF TDN.

Imagery Intelligence Information Systems and Supporting Communications

Imagery Direction and Collection Management

IAS and the Requirements Management System (RMS) are the key automated information systems resources supporting MAGTF IMINT operations (see figure 4-10 on page 4-14).

Intelligence Analysis System

IAS is the principal intelligence information system tool. IAS automates MAGTF intelligence activities of direction, collection, processing, production, and dissemination of critical tactical intelligence from embedded databases and multiple sources. It is interoperable with JDISS and a wide range of other intelligence and reconnaissance systems. This allows for better identification and tracking of MAGTF IRs, and development and C2 of supporting collection, production, and dissemination activities, both within the MAGTF as well as with other services, JTF, theater, and national intelligence operations. Various configurations of IAS are fielded from the MEF CE through battalion and squadron command echelons. IAS contains a limited automated collection management tool for imagery, as well as for other organic intelligence collection.

Basic System. IAS is capable of communication and data exchange at both the GENSER and SCI levels via the MAGTF TDN. Composition and size will vary at each echelon, but the IAS essentially consists of data storage devices, workstations, and input/output devices. Workstations at all echelons will share common software applications.

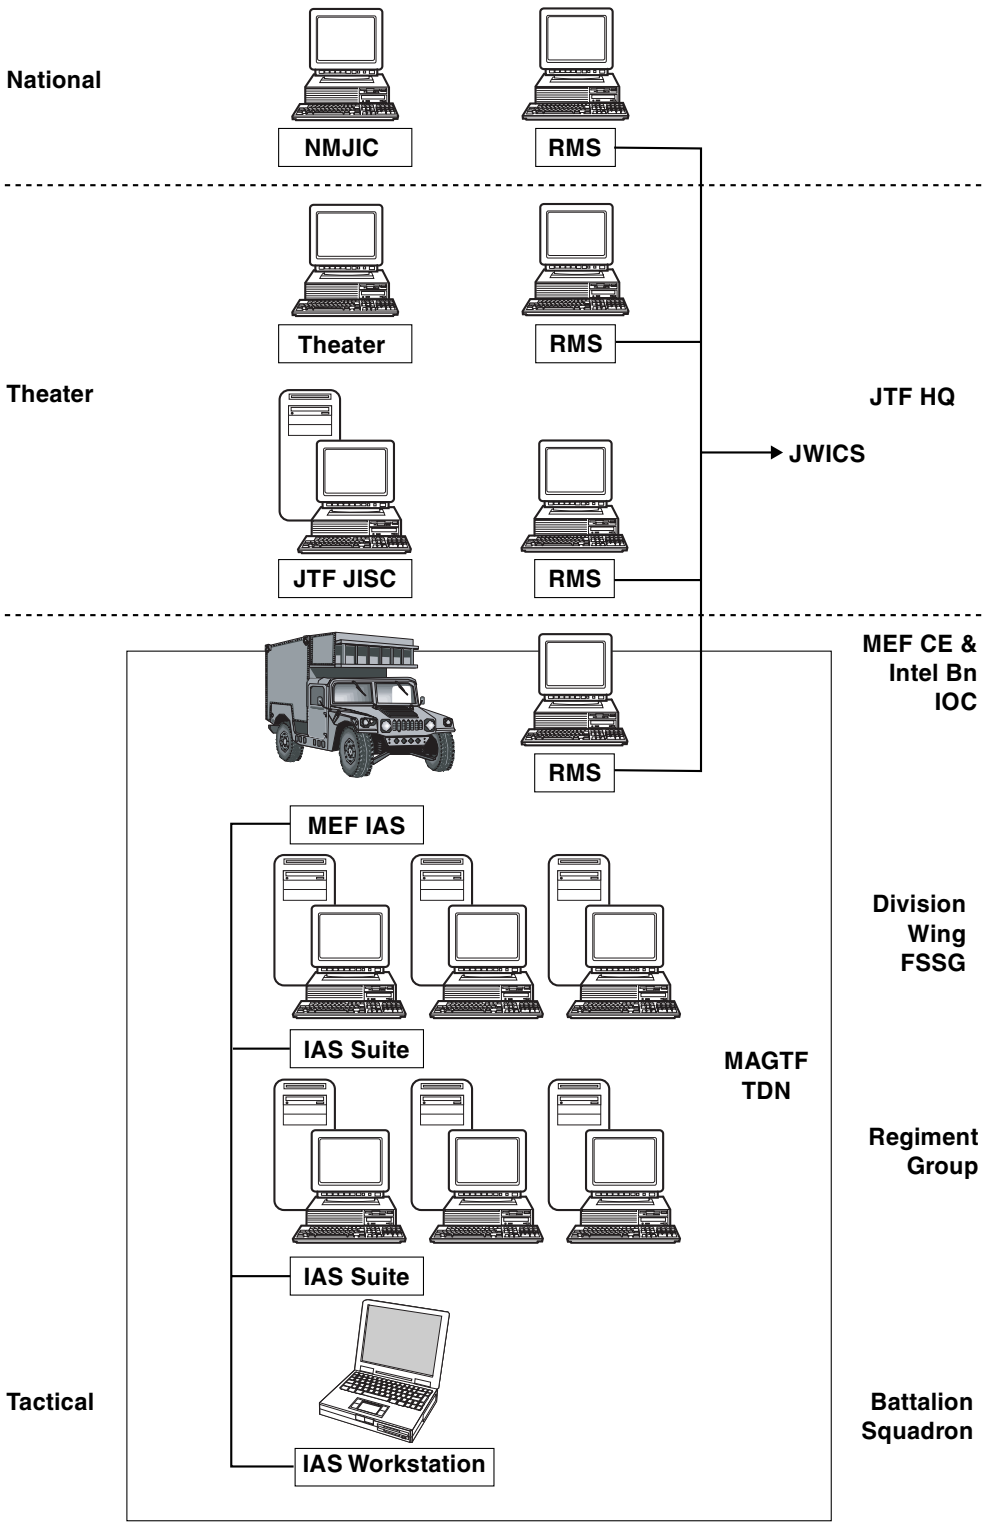

Figure 4-10. Imagery Direction and Collection Management.

Configuration. IAS consists of three configurations (see figure 4-11): MEF IAS, IAS suite, and the IAS workstation. The MEF IAS consists of two shelters mounted on HMMWVs and is used at the MEF CE level. The IAS suite consists of team portable equipment and will be used in the MEU CE and at division, MAW, regiment, and MAG headquarters. Finally, the IAS workstation consists of a single computer workstation and will be organic to battalion and squadron intelligence sections.

Features. The IAS provides connectivity and interoperability with most MAGTF intelligence, reconnaissance and other C2 systems, and with other services, JTF, theater and national intelligence organizations and data bases. IAS features improve the intelligence functions at all echelons of the MAGTF by providing a semi-automated all-source intelligence fusion center. It is capable of rapid access to and dissemination of critical, perishable tactical intelligence concerning terrain, weather, and enemy situation at all command levels. The IAS incorporates the capability to disseminate imagery throughout the MAGTF via SIDS. It facilitates display, processing, analysis, preparation of intelligence products, and dissemination of intelligence products.

Requirements Management System

RMS provides the MAGTF and other users with a comprehensive national imagery collection management capability. RMS allows MEF collection managers to access the national imagery requirements tasking and tracking system (RMS terminals are also located at the MARFOR headquarters, MCIA Suitland and with the Marine Corps DRO). RMS users generate imagery requirements nominations interactively via networked RMS or RMS-supported workstations. The nominations are automatically transferred to the appropriate review authority, and upon validation and prioritization, taskings are transmitted by RMS to the collection, exploitation, production, and dissemination organizations.

System Configuration. RMS is an SCI-high system. The major components include a file server,

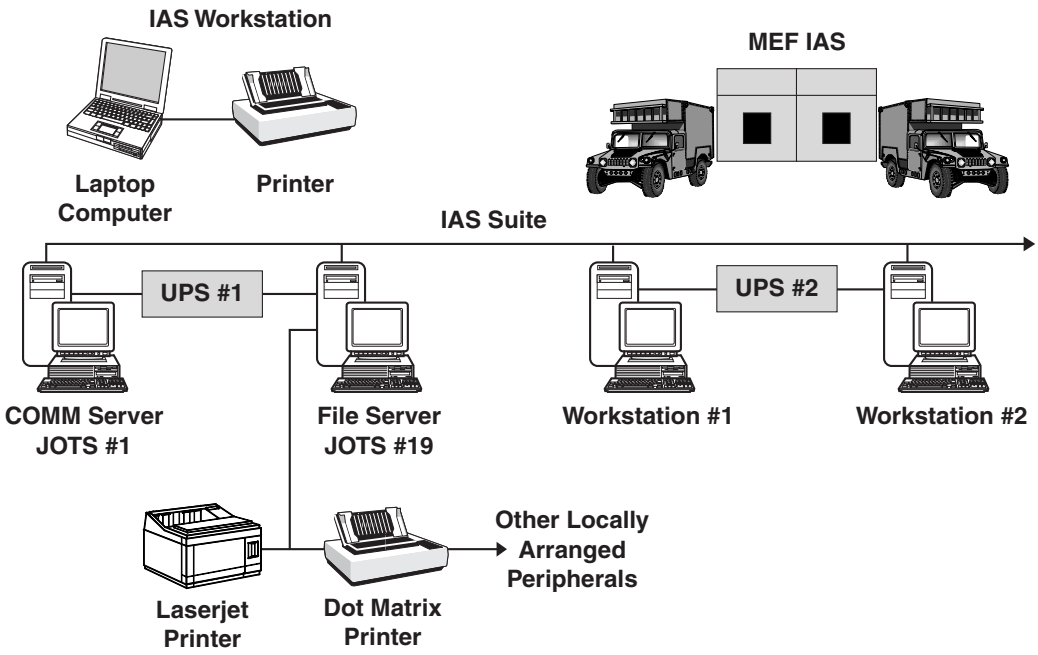

Figure 4-11. Intelligence Analysis System.

tape library system, access server for remote troubleshooting, a network laser printer, and the workstation itself.

RMS Connectivity. RMS communications connectivity requirements include JWICS and defense special security communications system (DSSCS).

Imagery Collection

The Marine Corps relies on both organic (see figure 4-12) and external collection assets for its imagery. The following paragraphs present MAGTF organic imagery collection assets and key C2-related information.

Advanced Tactical Airborne Reconnaissance System

The ATARS suites reside with the F/A-18D squadrons. ATARS-equipped F/A-18D aircraft will provide the MAGTF with organic manned aerial imagery reconnaissance capability in support of IMINT operations. ATARS is capable of infrared, EO, and radar imagery collection, and provides high resolution, day and night imagery support in all weather conditions, through both overflight and long-range standoff. The F/A-18D's long-range standoff capability is made possible with the installation of an upgraded, all-weather SAR system. Imagery is recorded and data-linked via integration with the ATARS sensor suite. The tactical interoperable ground data link (TIGDL) CDL will provide limited near-real time capability for dissemination of data on selected critical targets (down linked to the IIP's TEG), with subsequent manual tape download for exploitation of the complete track. Figure 4-13 depicts the F/A-18D systems architecture.

Unmanned Aerial Vehicles

UAVs provide MAGTFs a valuable aerial reconnaissance and imagery (video and infrared) capability.

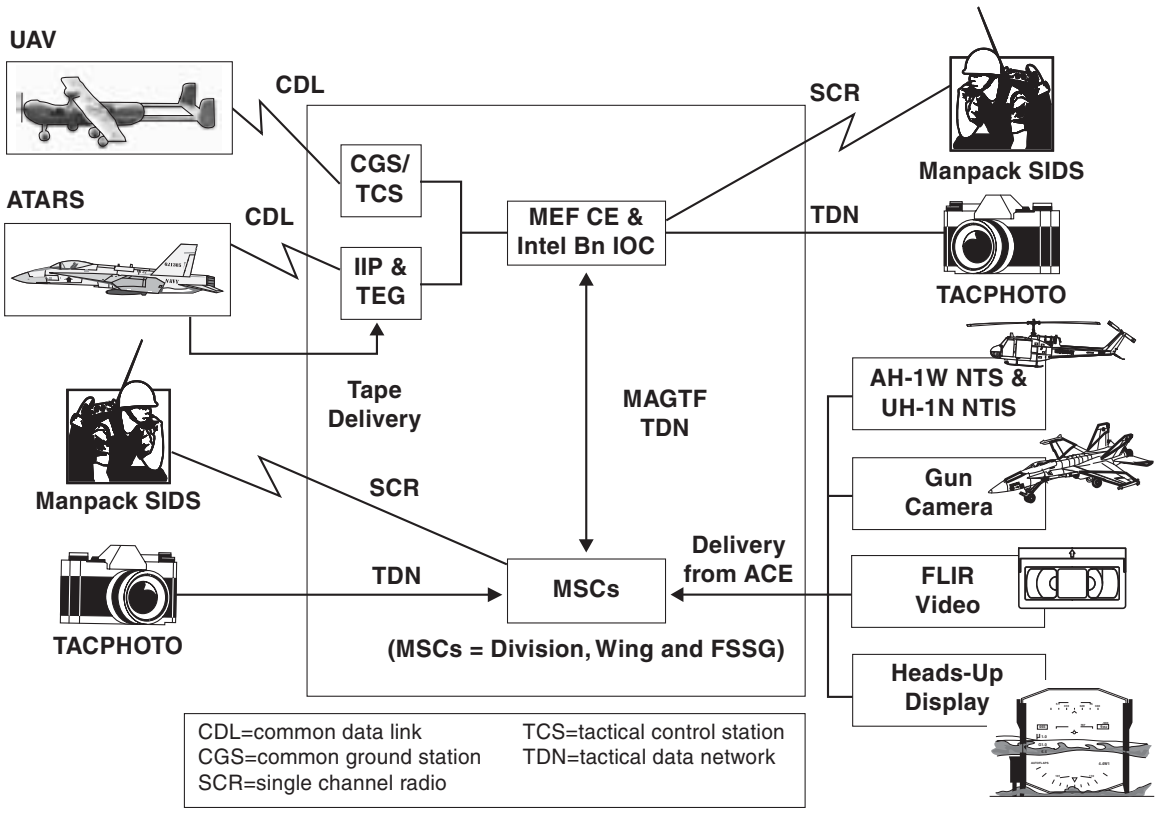

Figure 4-12. MEF Organic Imagery Collection.

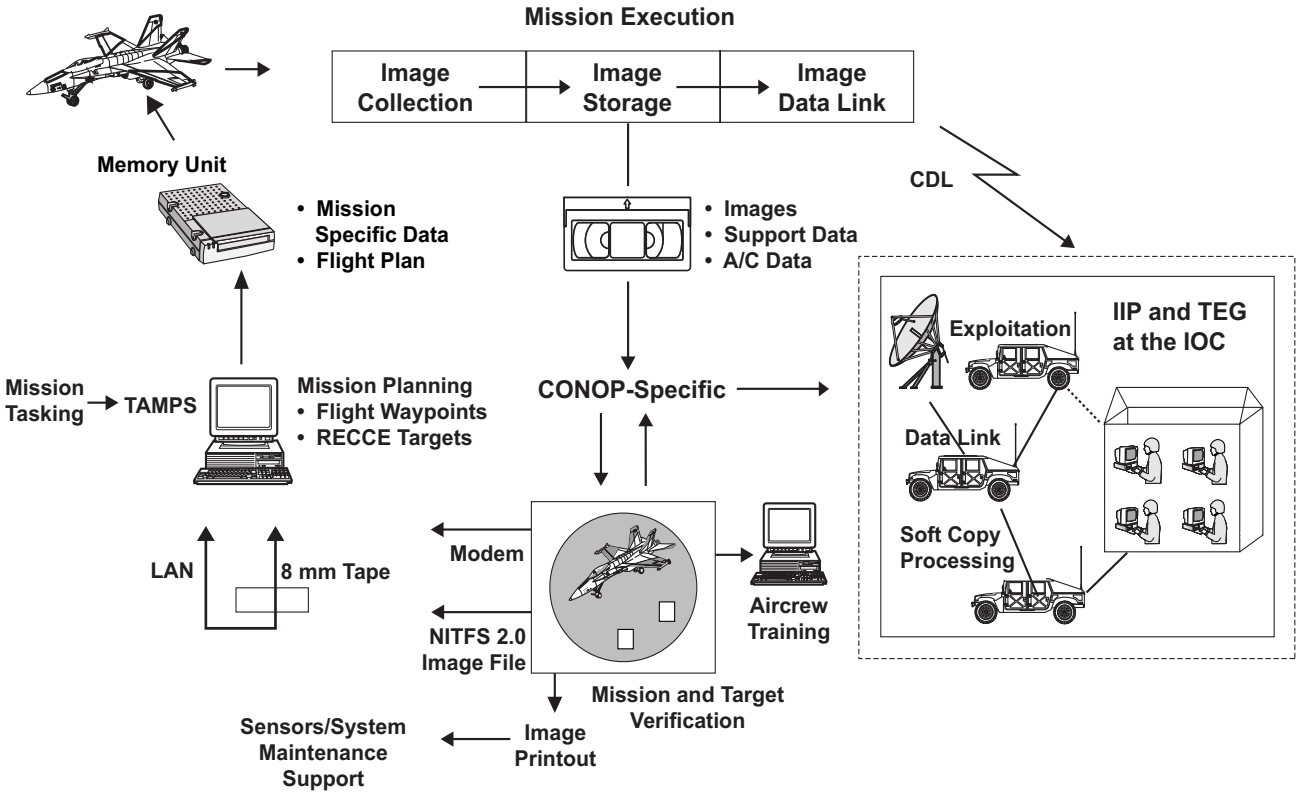

Figure 4-13. ATARS.

The Pioneer UAV resides in the VMU squadrons. Key UAV CIS resources are discussed in the following subparagraphs. See appendix D for additional information on UAV equipment and performance characteristics.

Ground Control Station 2000. The GCS-2000 is a small, modular, transportable control station for the UAV system. It controls and monitors the operations of the UAV and the installed payload. Since all pre-flight, takeoff, landing, post-flight, and maintenance procedures and functions can be performed from the GCS-2000, it can be used for controlling the UAV during all mission steps.

Portable Control Station. The portable control station (PCS) system—containing a flight control subsystem, a communications subsystem, and a power supply subsystem—allows UAV launch and recovery from a remote site, afloat or ashore, up to 40 kilometers from the GCS. The PCS allows the external pilot to perform takeoff/landing and flight control until command of the UAV is transferred to the internal pilot in the GCS.

Tracking Control Unit. The TCU controls all UAV tracking and communication functions, manages all up and down link data processing, and performs preflight and system diagnostic tests. The TCU houses all internal communication equipment and antenna subsystems for the GCS and is slaved to it by remoting cables.

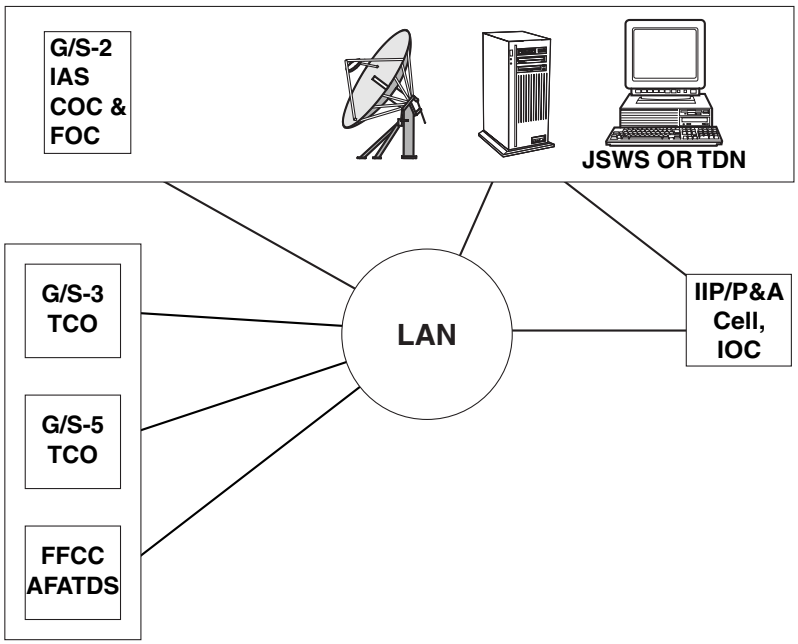
Remote Receiving Station. The RRS system is a miniature television receiver that can be attached or placed in direct support of commanders for real-time video pictures, supplemented with voice intelligence reports received from the GCS. There are two RRSs with each UAV system. Directional antennas allow video reception up to 30 kilometers from the UAV.

JSTARS Common Ground Station

Overview. The CGS is a mobile, tactical, multisensor ground station that provides the MAGTF CE with communications connectivity with the Air Force's E-8C and the capability to display, process, and disseminate acquired information. The CGS is organic to the MEF intel bn. Also receiving and processing MTI, FTI, and SAR data from the E-8C aircraft, the CGS is capable of receiving video data from UAVs, processed SIGINT from the Intelligence Broadcast Network, and secondary imagery from theater and national sources.

Basic System. The CGS is a HMMWV-mounted shelter system with component communications, computer, and mobile electric power systems. The CGS can be operated from either fixed positions or while mobile. Its crew of six operators can set up or tear down this system in 30 minutes and can support continuous operations. The CGS features an open-system architecture that enables rapid insertion of the latest government and commercial off-the-shelf technology. The ultrahigh frequency (UHF) SCDL provides the digital communications connectivity between the E-8C JSTARS airborne element and the MAGTF CE G-2 section's CGS, enabling the transmission of MTI, SAR, and FTI data acquired by JSTARS to support MAGTF target acquisition, situation development, battlespace management, and targeting functions. Figure 4-14 depicts the JSTARS CGS MAGTF systems architecture and concept of operations.

Subsystems. The CGS is comprised of six subsystems: data communications group, sensor interface group, distributed data processing group,



AFATDS=advanced field artillery tactical data system
COC=combat operations center
FOC=future operations center
FFCC=force fires coordination center
IAS=intelligence analysis system
IIP=imagery intelligence platoon
IOC=intelligence operations center
JSWS=JSTARS workstation
LAN=local area network
P&A Cell=production and analysis cell
TCO=tactical combat operations system
TDN=tactical data network

Figure 4-14. JSTARS and MAGTF Operations.

peripheral system group, voice communications group, and workstation group. CGS uses high performance CHS-2 SPARC 20 workstations, compatible with the MAGTF TDN.

Collection Capabilities. The E-8C carries a phased-array radar antenna in a 26-foot canoe-shaped radome under the forward part of the fuselage. The radar is capable of providing targeting and battle management data to all JSTARS operators, both in the aircraft and in the CGS module. These operators prepare intelligence reports or help coordinate aircraft, missiles or artillery fire support. With a range in excess of 155 miles, this radar covers an estimated 386,100 square miles in a single 8-hour sortie.

- **Wide Area Surveillance and Moving Target Indicator (WAS/MTI).** WAS/MTI are the radar's fundamental operating modes. WAS/MTI detects, locates, and identifies slow-moving targets. Through advanced signal processing, JSTARS can differentiate between wheeled and tracked vehicles. By focusing on smaller terrain areas, the radar image can be enhanced for increased resolution display. This high resolution defines moving targets and provides combat units with accurate information for attack planning.
- **Synthetic Aperture Radar/Fixed Target Indicator (SAR/FTI).** SAR/FTI produces a photographic-like image or map of selected geographic regions. SAR data maps contain precise locations of critical non-moving targets such as bridges, harbors, airports, buildings, or stopped vehicles. The FTI display is available while operating in the SAR mode to identify and locate fixed targets within the SAR area. The SAR and FTI capability used in conjunction with MTI and MTI history display allows post-attack assessments made by onboard or ground operators following a weapon attack on hostile targets.

Manpack SIDS

Overview. Manpack SIDS system provides the primary MAGTF capability for hand-held digital imagery reconnaissance (see figure 4-15 on page 4-20). Manpack SIDS consists of three digital cameras, three palmtop processors, and a base station providing ground reconnaissance units with the capability to take pictures and send the images back to the base station over selected communications paths. The base station then disseminates the images to the supported unit's intelligence section's IAS for follow-on analysis, production, and dissemination via the MAGTF TDN or other CIS resources.

Concept. Manpack SIDS is a tactical hand-held digital imagery collection and dissemination system designed to acquire, store, manipulate, and electronically transmit images derived from ground reconnaissance patrols. The system is comprised of a man-transportable outstation camera with processor and a base station processor with printer. The outstation, with its digital camera component, will be employed by MAGTF ground reconnaissance elements during operations for image acquisition. Imagery collected by the outstation may be stored for subsequent analysis or electronically transmitted to the base station over organic tactical communications for more timely analysis and intelligence production. The base station will be located at the ROC for receipt, manipulation, annotation, and subsequent dissemination of imagery to other intelligence elements or direct to subordinate units in accordance with specified intelligence reporting criteria.

Components and Connectivity. Manpack SIDS consists of three manportable outstations and one base station. The outstation's primary components are a digital camera with three lenses and a palm top computer. In addition, there is one night vision device per system used with the camera in low light situations. The outstation also comes with cables that attach the camera to the palm top, and the palm top to the encryption device and radio. The base station is primarily made up from the lap top computer and thermal printer. It also comes with the cables required to connect with the encryption device and radio (it is interoperable with the PRC-104, PRC-113, single-channel ground and airborne radio system,

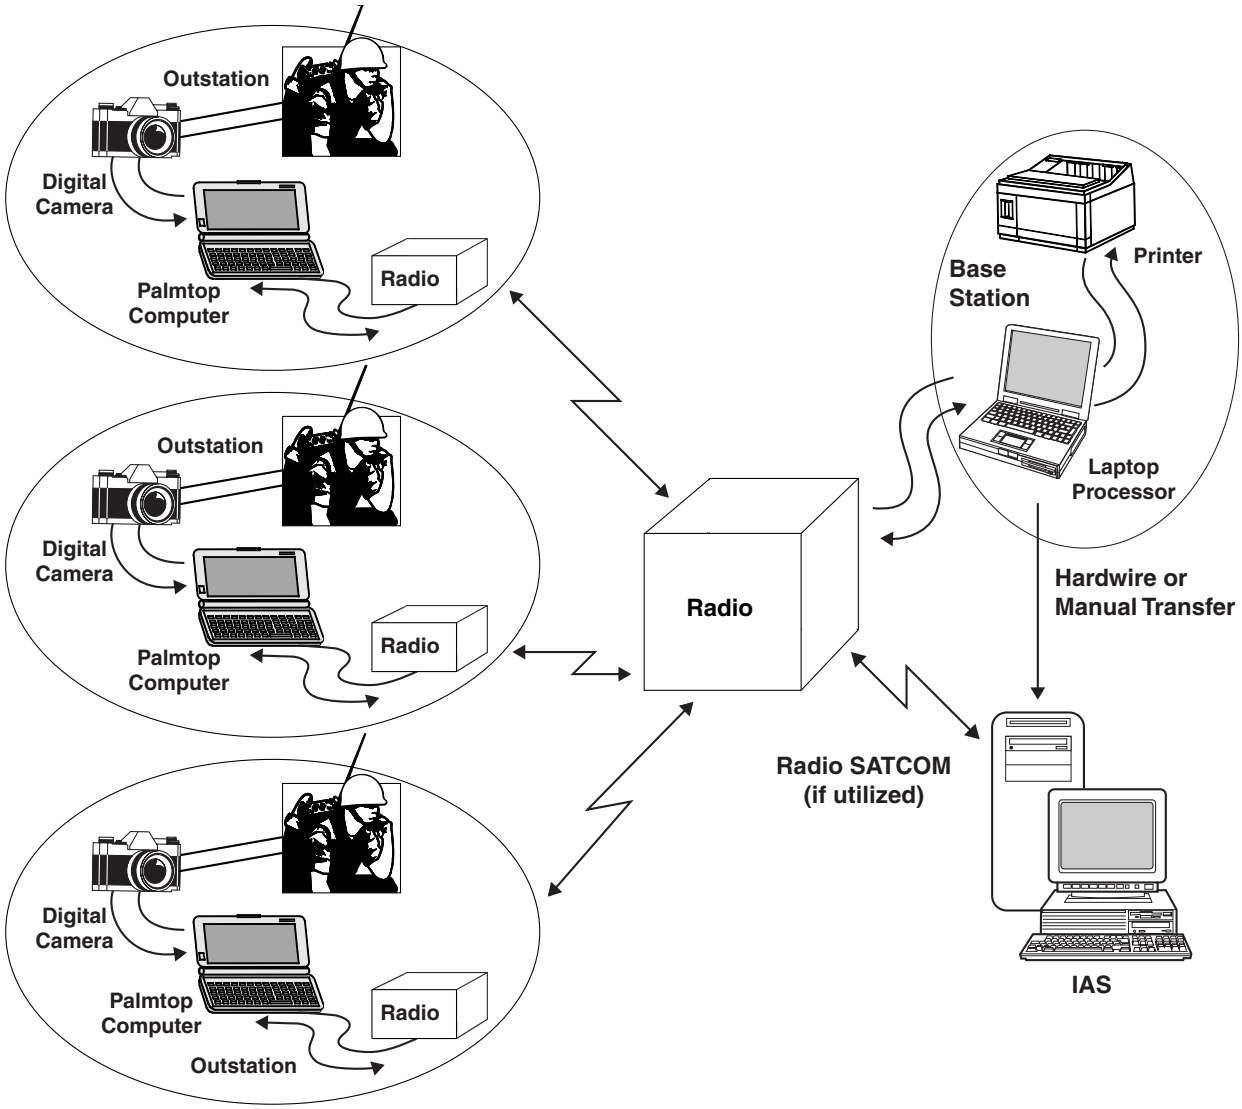


Figure 4-15. Manpack SIDS.

and various satellite communications resources). The base station is interoperable with the IAS via either the MAGTF TDN or other organic communications.

HML/A's NTS and NTIS

Components

- **AH-1W Night Targeting System.** The NTS FLIR's linear scanning array consists of 120 mercury cadmium telluride detector elements that scan left to right, then right to left to interlace the image. Information is then doubled to provide 480 lines of information. The super videocassette recorder (SVCR) automatically starts recording when the laser designator or weapons firing is activated or through command from the crew, and records in both super very high speed (VHS) and standard VHS formats. Finally, the television tracker is a video autotracker that works with both video and FLIR modes.
- **UH-1N Night Thermal Imaging System.** The NTIS components are similar to that of the NTS less the NTS's laser designator and television tracker capabilities. Its videocassette recorder (VCR) records only in standard VHS format.

Employment. The NTS and NTIS systems were fielded to provide the MAGTF with all-weather, day/night, autonomous attack, C2 and utility helicopter capabilities. Embedded within each system is a VCR to allow the aircrew to record engagements for debrief, collect BDA information, and to aid in target identification, acquisition, and engagement in a high threat environment while minimizing exposure time. The fielding of these systems greatly expanded the HML/A squadrons' traditional reconnaissance and surveillance capabilities because of their upgraded sensors and the VCR capabilities. However, the VCR does not record any other supporting information (e.g., geographic coordinates) beyond the basic imagery. Accordingly, helicopter aircrews will record concurrently an audio of the mission to make the tape more useful for post-mission debriefings and users.

Both helicopters, the AH-1W and UH-1N, can be employed in sections or as part of teams to scout ahead of friendly troops or to conduct visual and/or imagery reconnaissance of areas of interest, objectives, routes, point targets, etc. Because each is vulnerable to ground fire and provides other critical support to MAGTF (e.g., the AH-1W's fires capability; the UH-1N's C2 and utility capabilities), rarely will either be employed in a dedicated reconnaissance role. A more likely role for the AH-1W would be an armed reconnaissance mission as a function of offensive air support to deep air support operations. In such a mission the AH-1W would seek out and engage a given target set within a specified area, with a concurrent mission to collect intelligence data. Another likely mission for the AH-1W is armed interdiction, in which AH-1's would be deployed to engage a specific, known target and collect intelligence information.

Finally, both the AH-1W and UH-1N can be employed to conduct point or route reconnaissance missions of designated objective areas or by flying a route while video/FLIR recording to provide GCE, ACE or CSSE forces with a valuable early look at planned areas of operation.

All intelligence missions typically will be performed in addition to the primary missions of armed escort and rotary-wing close air support. During the conduct of any mission, both aircraft have a secondary mission of conducting aerial reconnaissance, and the aircrew would employ the NTS and NTIS to collect and store imagery data for post-mission follow-on analysis.

Tactical Photo

TACPHOTO is a digital camera system for units that normally return to base (i.e., flight crews, CI teams, and scout snipers), and have the capability to download acquired images into other intelligence information systems for follow-on intelligence exploitation. TACPHOTO uses the same digital camera and a similar concept of employment as Manpack SIDS. It consists of a digital camera, three lenses, PCMCIA card hard drive and card reader, cables, and the imagery receive and manipulate software.

Imagery Processing, Exploitation, and Production Capabilities

The Marine Corps possesses a limited organic imagery processing, exploitation, and production capability. Access to national, joint, theater, and other-Service processing and production capabilities will therefore be important elements of the Marine Corps imagery architecture (see figure 4-16 on page 4-22). The following provides descriptions of key IMINT processing, exploitation, and production information systems.

Dissemination Element

The MCIA's DE (formerly known as JSIPS) provides exploitation and dissemination of national imagery to MAGTFs and other Marine Corps units (to include the supporting establishment). The DE receives, stores, and exploits digital NRT imagery from national and theater imagery collection platforms. It also displays imagery in softcopy format for immediate exploitation. MCIA's intelligence, imagery, and database systems and requirements include defense message system,

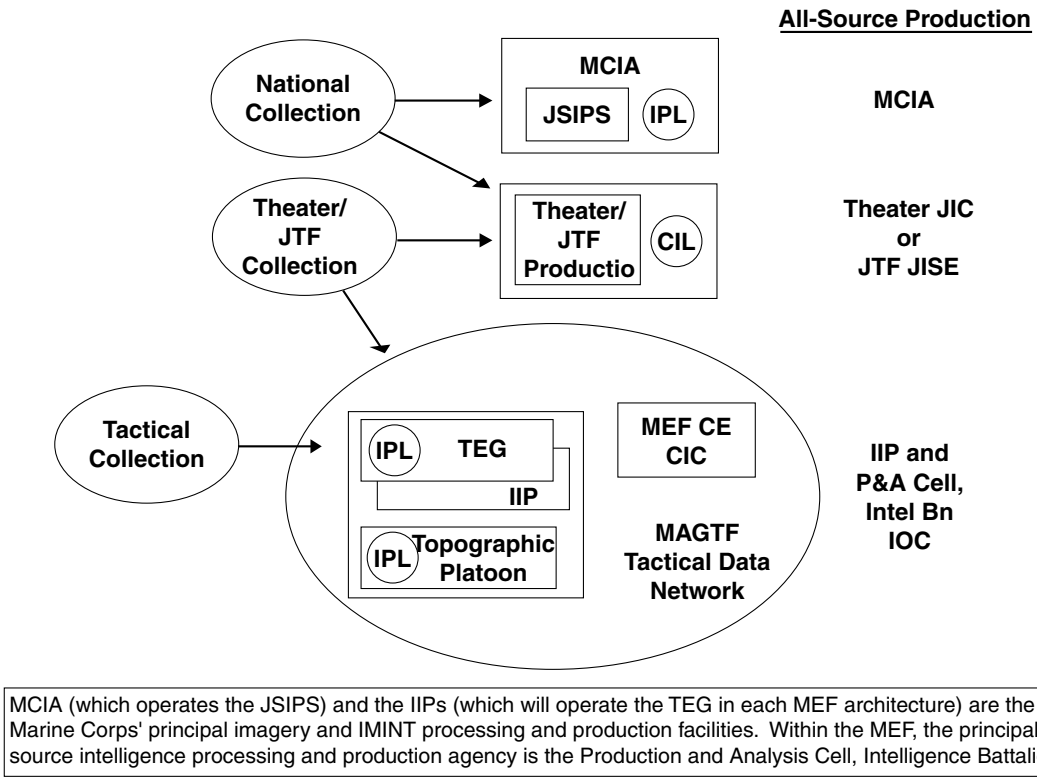

Figure 4-16. MEF Imagery Processing and Production.

JWICS, SIPRNET, 5D imagery server or IPL, RMS, imagery exploitation software system (IESS) data base, and the NIMA Delivery System (NDS).

Tactical Exploitation Group

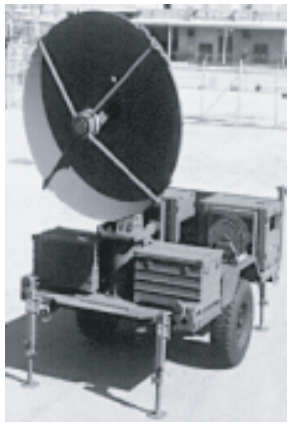
The TEG is a key MAGTF IMINT system and the only imagery exploitation and analysis tool available within the MEF (see figure 4-17). It is organic to each MEF's intel bn's IIP. It is capable of receiving, exploiting, and producing imagery and IMINT products and reports via its system architecture (see figure 4-18). The TEG provides the capability to receive, process, store, exploit, and disseminate imagery, to include ATARS EO, infrared, and radar imagery; U-2 SAR imagery; and secondary imagery products from the MCIA and theater JIC/JACs. Additionally, the TEG's equipment suite provides the capability to exploit film-based imagery and output from digital cameras such as Manpack SIDS, and heads-up displays, FLIR, and gun camera tapes from various tactical aircraft. Once received, processed, and exploited, the imagery is then transmitted over available SIDS device(s), MAGTF TDN or other CIS resources. Upon fielding of the TIGDL CDL, NRT exploitation and processing of ATARS imagery will be possible; until then, imagery data tapes must be downloaded and disseminated to the TEG post-mission. Even with the TIGDL CDL, only selected priority images will be down linked; the remaining imagery data is stored on tape and downloaded following recovery.

The TEG is packaged in three HMMWVs and three trailers. Due to its weight and balance, the TEG requires additional external lift capability to move the IIP and TEG within the area of operations. This additional lift is not resident within the intel bn and must be provided either by the MEF headquarters group or some other external source.

The initial operational capability TEG allows for the processing of F/A-18(R/C) mission tapes and data link and handles preprocessed national, U-2, UAV, and digital camera systems imagery. The

Vehicles and Power

Vehicle and Work Tent



Tactical Data Link

full capability TEG provides interoperability with all Common Imagery Ground/Surface Systems (CIGSSs) baseline sensors (e.g., ATARS, Global Hawk) and handles all other preprocessed national imagery transmission format (NITF) imagery data.

Image Product Library

The IPL is the migration system to replace the legacy 5D System. IPL supports the storage and dissemination of imagery and imagery products, providing a library of information to imagery customers worldwide. IPL uses a standard Intelink or Intelink-S client to provide user access to this library, and supports both data push and data pull, via user profiling. The IPL stores imagery in NITF 2.0, TIFF, and other graphical formats.

Libraries are composed of three types: product, command, and national. The three types are differentiated by content, storage size, performance, and responsibility for operations and management. They are alike in that each type may contain digital imagery or digital imagery products from all sources including tactical, theater, national, civil, and commercial collection systems. All libraries share common digital imagery standards.

IPLs contain shared, restricted, or both types of imagery and imagery products required to support individual organizations. Each organization will determine the population of and manage its IPLs. The imagery and imagery-based products consist of tactical, theater, national, civil, and commercial imagery and imagery-based products. Most of the data stored on IPLs will be imagery products with

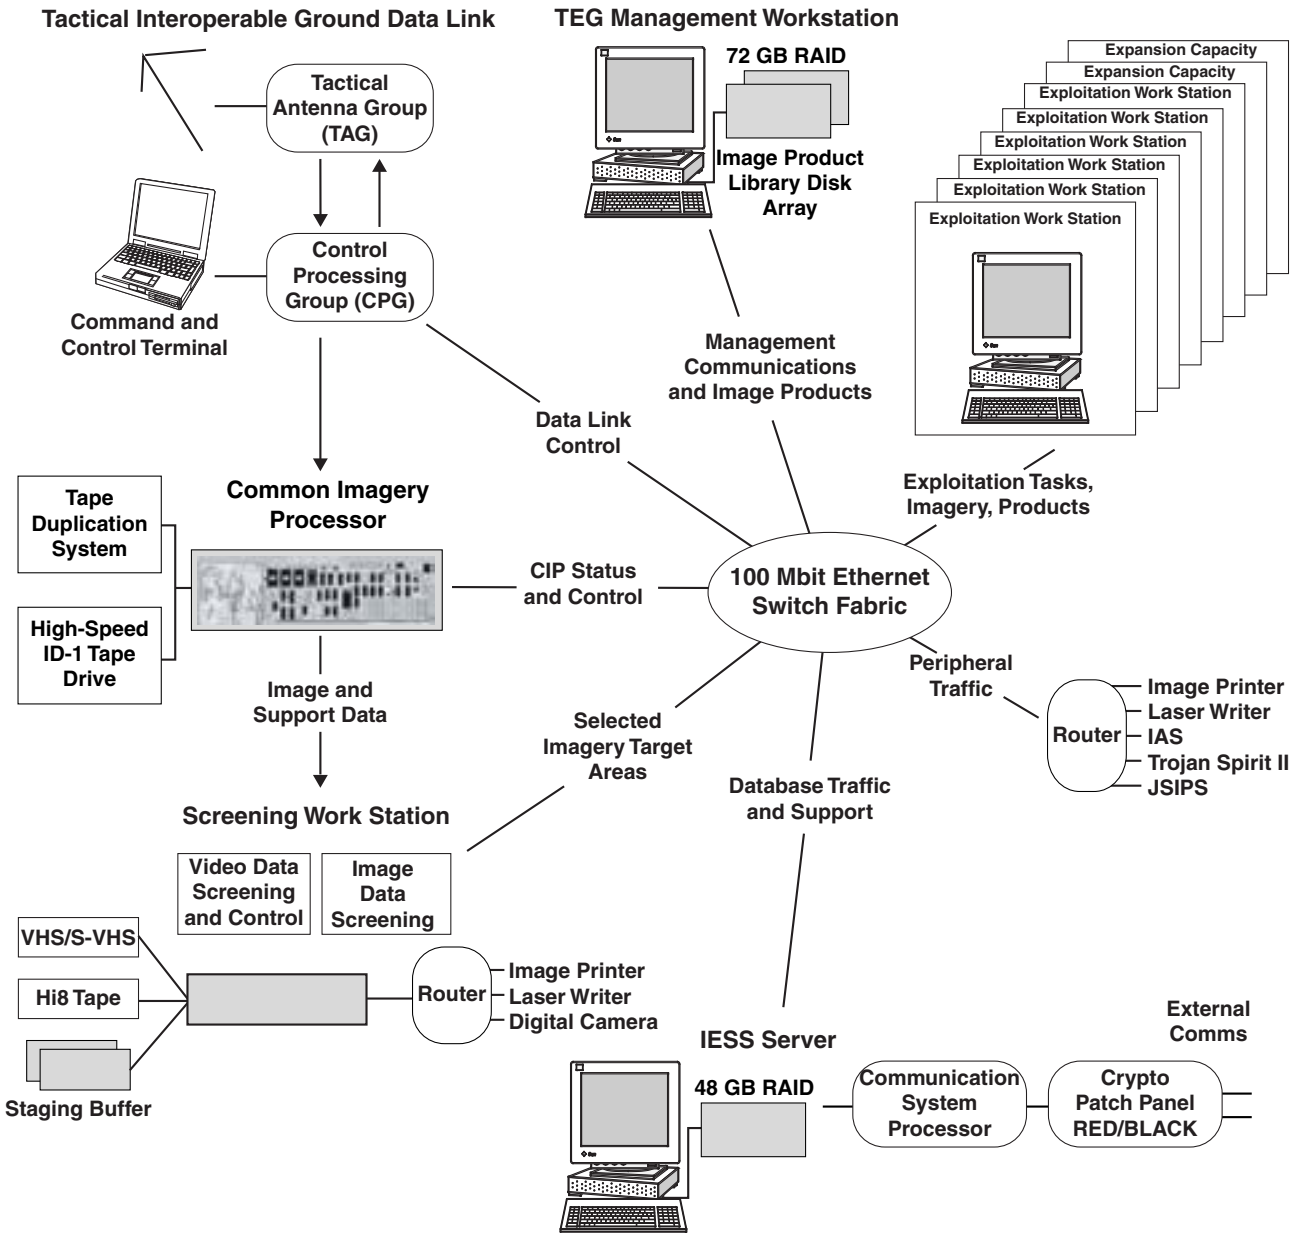

Figure 4-18. IIP/TEG Systems Architecture.

the owner determining the mix between imagery and imagery products, the size of their IPLs, their interfacing organizations, and the products requiring storage. NIMA will provide the updated IPL management software. IPLs are based upon existing 5D capabilities, scaled for size and performance, and some are portable. IPLs support various levels of command, CIGSS sites, and other organizations outside the command structure of the services requiring the use of libraries. When IPLs are integrated into the 17+ CIGSS ground station architectures, processed tactical imagery (still or motion) is fed to an IPL, acting as an imagery buffer, at the ground station. Stored imagery is then pulled or pushed to the exploitation workstations, exploited, then sent to the public access IPL for dissemination.

IPLs will be capable of importing, storing, exporting and managing imagery, image-based

products, and associated metadata. IPLs have the capability to retain digital imagery data in on-line, near-line, and off-line storage media. Each IPL maintains a catalog populated with metadata of its imagery and imagery product holdings. The national IPL supports up to 1,300 image requests per day and up to 900 gigabytes (GB) for on-line imagery storage. The IPL should not take longer than 8 minutes to transfer a full frame (930 megabytes [MB]) national image to any requesting client (assuming fiber distributed data interface and no LAN contention).

Figure 4-19 provides a broad depiction of the services, applications, and scope within the IPL.

Imagery CIS Architecture

Figures 4-20 on page 4-26 and 4-21 on page 4-27 summarize the information discussed throughout this chapter and depict the internal IMINT CIS architecture for a MEF, and the broader IMINT CIS architecture through the theater and national levels.

IMINT Communications and Information Systems Planning Considerations

The following identifies key CIS requirements and planning considerations in support of MAGTF IMINT operations.

- Ensure that the MAGTF CE, IIP elements, and other MAGTF units are included in the distribution of IMINT-related address indicator groups to receive pertinent JTF, Navy, theater, and national intelligence and IMINT products.
- Determine and coordinate radio net requirements, supporting frequencies, and operational

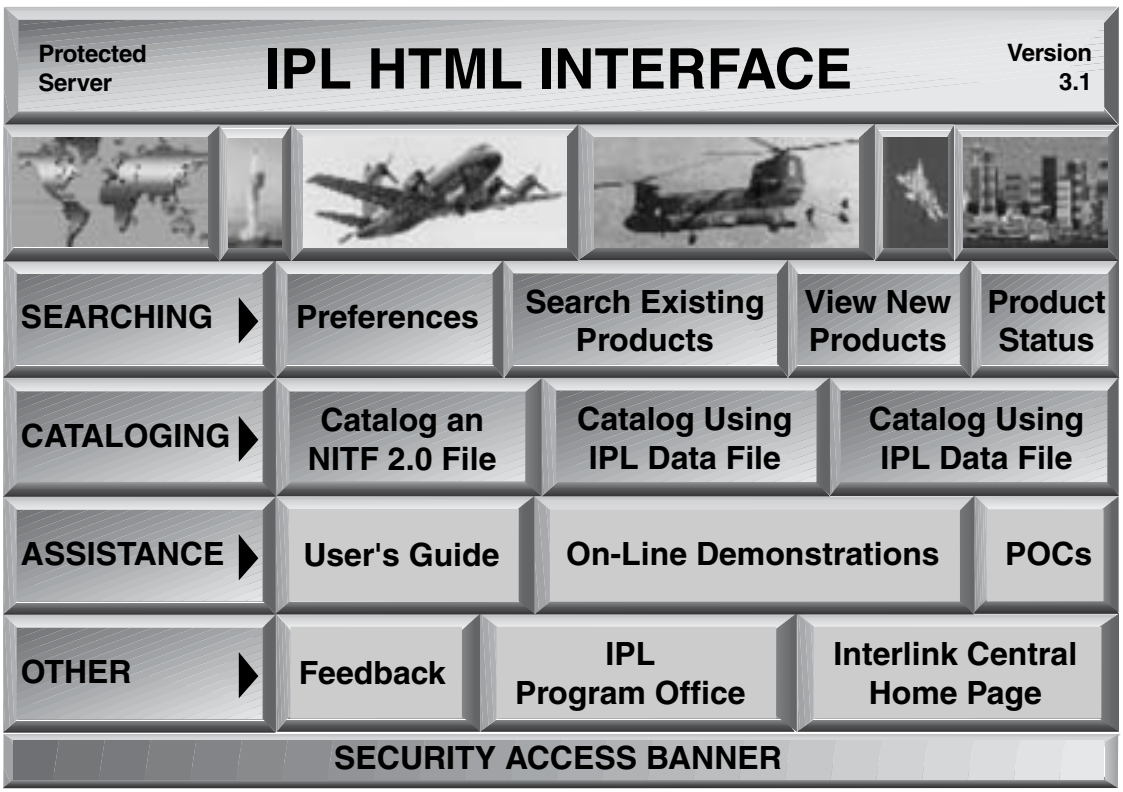

Figure 4-19. Image Product Library.

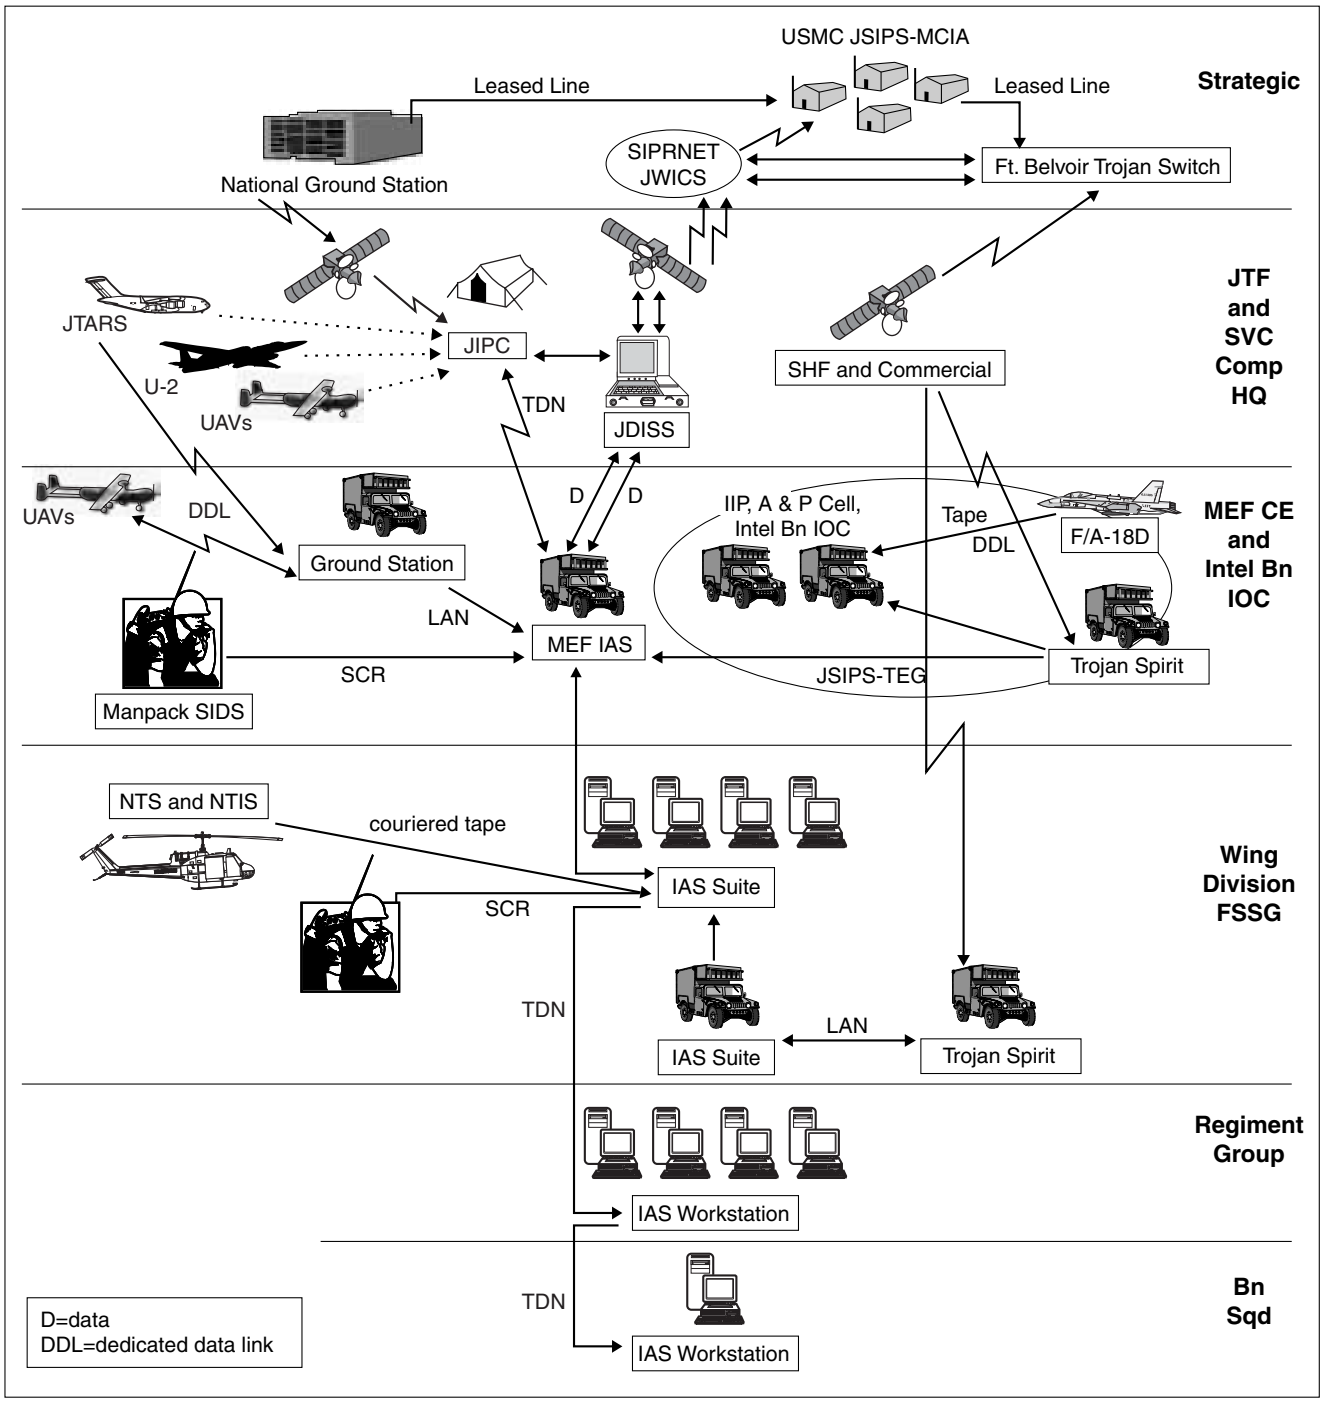

Figure 4-20. MEF Internal Imagery CIS Intelligence Architecture.

procedures in support of IMINT operations (external to MAGTF, internal MAGTF, intelligence broadcasts, retransmission sites, routine and time-sensitive operations, etc.).

- Coordinate IMINT CIS activation and restoration priorities and supporting procedures.
- Establish, operate, and manage unique IMINT communications requirements (e.g., with MCIA for the JSTARS CGS).
- Identify and procure communications security materials system (CMS) requirements for unique IMINT communications.

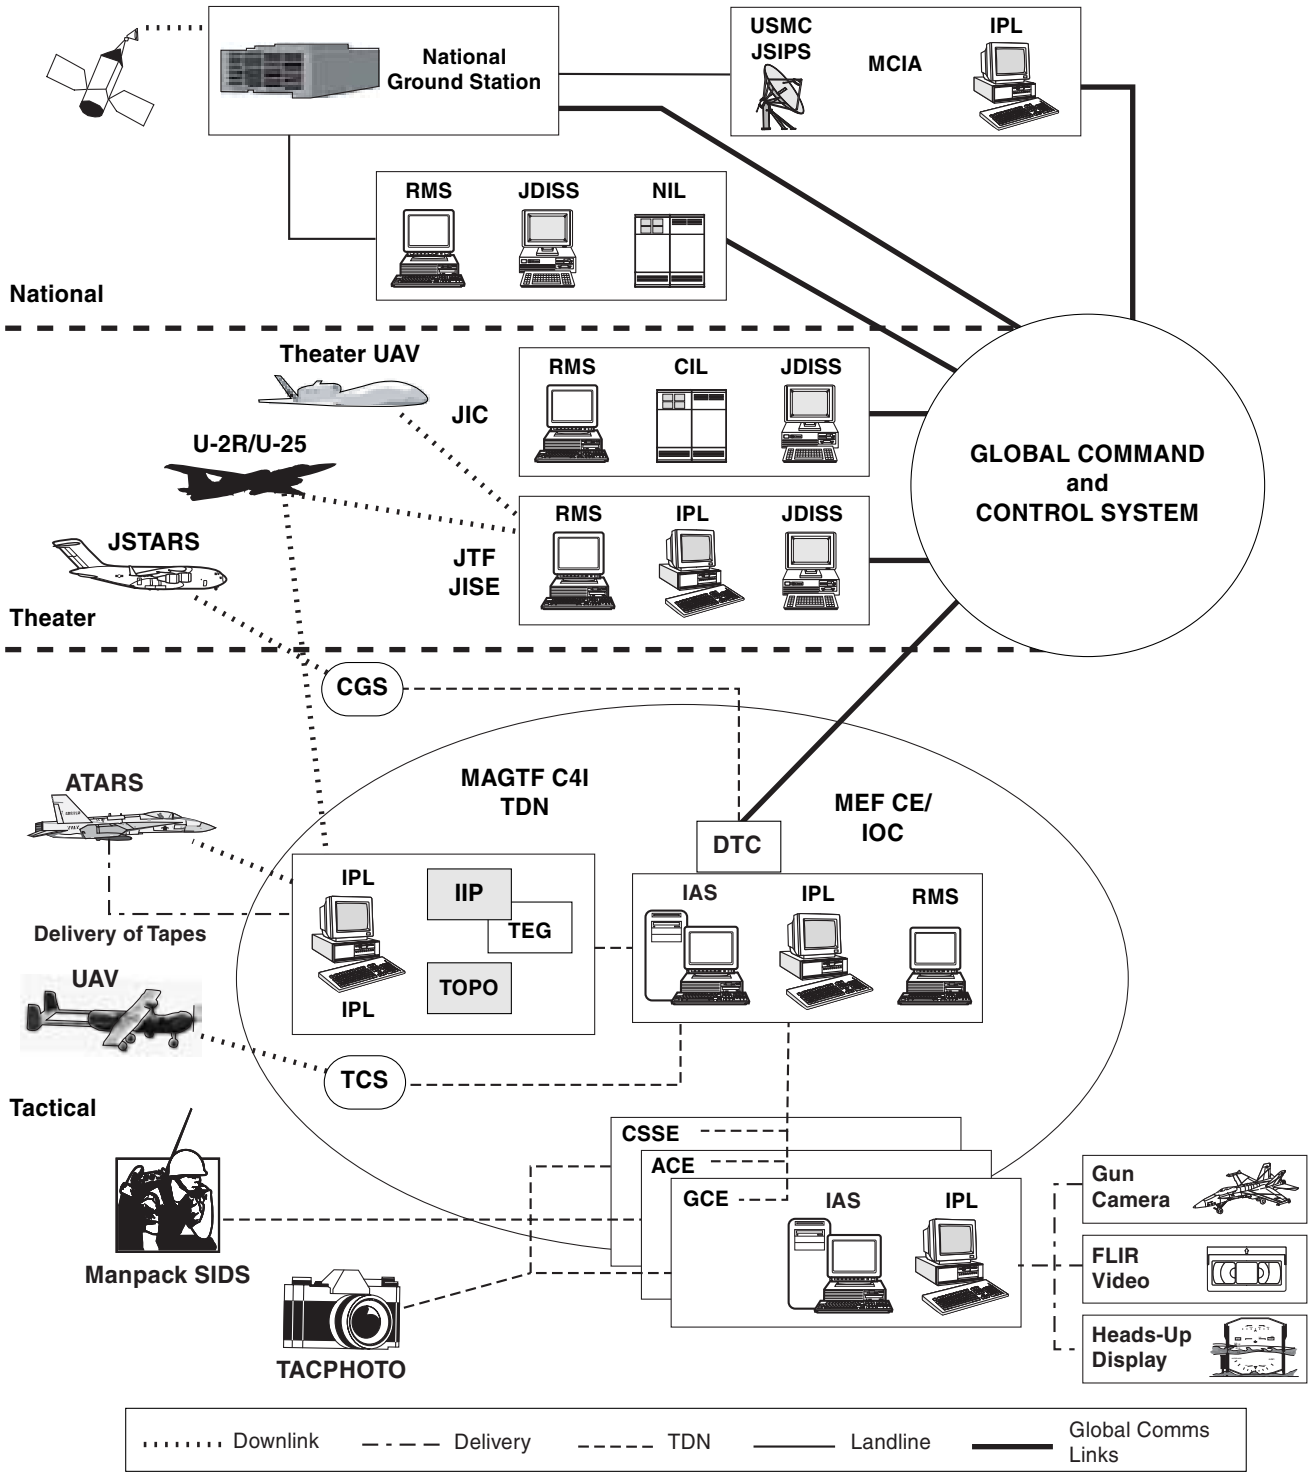

Figure 4-21. MEF Through National IMINT CIS Intelligence Architecture.

- Determine and coordinate wire communications (to include telephones) supporting IMINT operations.
- Determine and coordinate LANs and WANs and unique intelligence network information systems requirements in support of IMINT operations (hardware, software, internet protocol addresses, etc.).
- Integrate MAGTF IMINT elements' CIS operations with those of other MAGTF and pertinent JTF and other components intelligence and reconnaissance units (mutual support, cueing, etc.).
- Integrate CIS of IMINT elements employed in general support with collocated GCE, ACE, CSSE, and other MAGTF elements (e.g., integration of UAV squadron RRS with supported GCE units to provide time-sensitive reporting, coordination of maneuver).
- Coordinate MAGTF IPL and Manpack SIDS administration and operations.
- Coordinate IMINT CIS and collection, production, and dissemination operations and procedures with other Services', allied and coalition forces' IMINT and all-source intelligence operations.

CHAPTER 5. OPERATIONAL PLANNING AND EXECUTION

Whether performed at the national or the battalion/squadron level, the key functions of planning are—

- Lead to a plan that directs and coordinates action.
- Develop a shared situational awareness.
- Generate expectations about how actions will evolve and how they will affect the desired outcome.
- Support the exercise of initiative.
- Shape the thinking of planners.

Marine Corps Planning Process

The Marine Corps Planning Process (MCPP) helps organize the thought processes of a commander and the staff throughout the planning and execution of military operations. The MCPP focuses on the threat and is based on the Marine Corps warfighting philosophy of maneuver warfare. It capitalizes on the principle of unity of effort and supports the establishment and maintenance of tempo. The MCPP steps can be as detailed or as abbreviated as time, staff resources, experience, and the situation permit. The command and staff actions at all echelons must apply the MCPP. From the Marine Corps component headquarters to the battalion/squadron level, commanders and staff members must master the MCPP to be full participants in integrated planning. Additionally, the MCPP complements deliberate or crisis action planning (CAP) as outlined in the Joint Operation Planning and Execution System (JOPES).

The MCPP establishes procedures for analyzing a mission, developing and analyzing courses of action (COAs) against the threat, comparing friendly COAs against the commander's criteria and each other, selecting a COA, and preparing an OPORD for execution. The MCPP organizes the planning process into six steps (see figure 5-1).

The MCPP provides the commander and the commander's staff a means to organize their planning activities and transmit the plan to subordinates and subordinate commands. Through this process, all MAGTF levels of command can begin their planning effort with a common understanding of the mission and commander's guidance. The six integrated steps of this process follow.

Mission Analysis

Mission analysis is the first step in planning. Mission analysis reviews and analyzes orders, guidance,

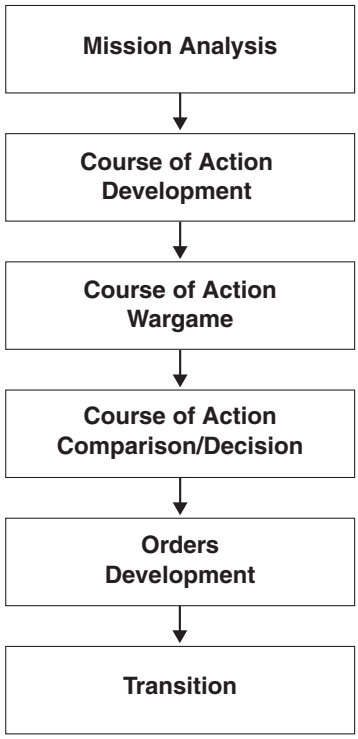

Figure 5-1. The Marine Corps Planning Process.

and other information provided by higher headquarters and produces a unit mission statement. Mission analysis drives the MCPP.

COA Development

During COA development, the planners use the mission statement including higher headquarters tasking and intent, commander's intent, and commander's planning guidance to develop the COA(s). Each prospective COA is examined to ensure that it is suitable, feasible, distinguishable, acceptable, and complete with respect to the current and anticipated situation, the mission, and the commander's intent. In accordance with the commander's guidance, approved COAs are further developed in greater detail.

COA Wargaming

COA wargaming involves a detailed assessment of each COA as it pertains to the enemy and the battlespace. Each friendly COA is war-gamed against selected threat COAs. COA wargaming assists the planners in identifying strengths and weaknesses, associated risks, and asset shortfalls for each friendly COA. COA wargaming identifies branches and potential sequels requiring additional planning. COA wargaming provides the most reliable basis for understanding and improving each COA.

COA Comparison and Decision

In COA comparison and decision, the commander evaluates all friendly COAs—against established criteria, then against each other—and selects the COA deemed most likely to accomplish the mission.

Orders Development

During orders development, the staff takes the commander's COA decision, mission statement, commander's intent, and guidance and develops orders to direct the actions of the unit. Orders serve as the principal means where the commander expresses decision, intent, and guidance.

Transition

Transition is an orderly handover of a plan or order as it is passed to those tasked with execution of the operation. It provides those who will execute the plan or order with the situational awareness and rationale for key decisions necessary to ensure there is a coherent shift from planning to execution.

Interactions among various planning steps allow a concurrent, coordinated effort that maintains flexibility, makes efficient use of time available, and facilitates continuous information sharing. Appendix F captures major IMINT planning considerations and activities in support of MAGTF operations, cross-referencing each with the MCPP step and major staff planning activities that they are most associated.

Joint Planning Processes

Joint Deliberate Planning

The deliberate planning process is used by the joint staff and combatant commanders to develop plans in support of national strategy. The Joint Strategic Capabilities Plan (JSCP) apportions forces and resources for use during deliberate planning by the combatant commanders and their Service component commanders. Figure 5-2 illustrates how the MCPP fits within and supports the joint deliberate planning process.

Crisis Action Planning

CAP is conducted in response to crises where national interests are threatened and a military response is being considered. In CAP, the time available for planning at the national level may

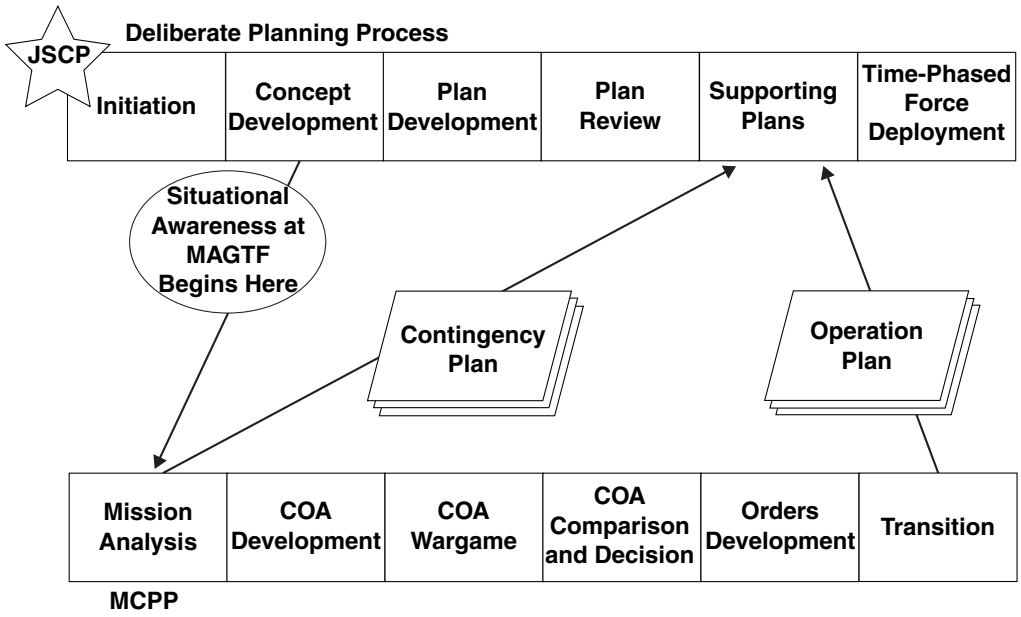

Figure 5-2. The MCPP and the Joint Crisis Action Planning Process.

be reduced to as little as a few days. CAP procedures promote the logical, rapid flow of information and the timely preparation of campaign plans or OPORDs. Figure 5-3 illustrates how the MCPP fits within and supports the joint crisis action planning process.

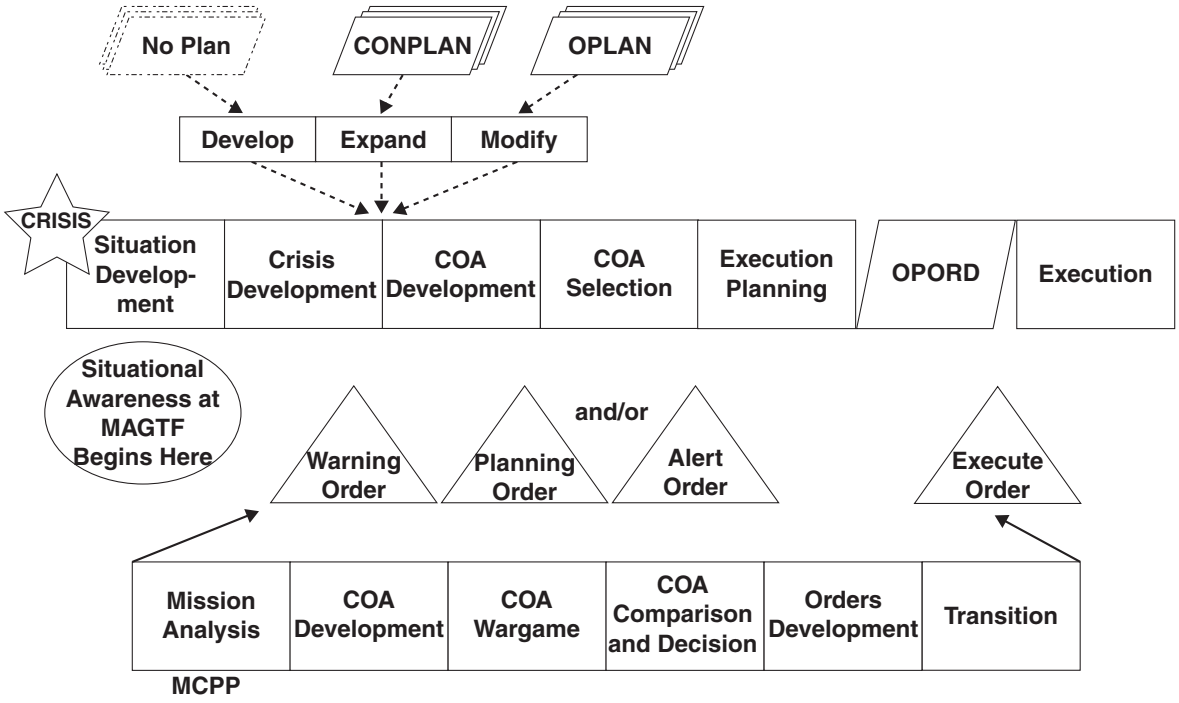

Figure 5-3. The MCPP and the Joint Deliberate Planning Process.

Planning and Imagery Intelligence

Planning and Intelligence Cycle

IMINT planning and execution is conducted concurrent with six phases of the intelligence cycle. The first phase is planning and direction. It consists of those activities that identify pertinent IRs and provides the means for satisfying those requirements. Intelligence planning and direction is a continuous function and a command responsibility. The commander directs the intelligence effort; the intelligence officer manages this effort for the commander based on the intent, designation of commander's critical information requirements (CCIR), and specific guidance provided during the planning process. Planning and direction functions include:

- Requirements development.
- Requirements management.
- Collection management.
- Production management.
- Dissemination management.
- Planning the intelligence support system.

The intelligence cycle is a procedural framework for the development of mission-focused intelligence support. It is not an end, nor should it be viewed as a rigid set of procedures carried out in an identical manner on all occasions. The intelligence cycle must be applied in a manner that develops the required intelligence in the most effective way.

The application of the intelligence cycle will vary during mission planning and execution. Application of the intelligence cycle is driven by IRs. In theory, a unique iteration of the intelligence cycle is carried out for each individual IR. In practice, particularly during planning, IRs are grouped together and satisfied through a single, intelligence development process that concurrently addresses all IRs, including IMINT requirements. During planning, the application of the intelligence cycle supports mission analysis, course of action development and course of action wargame by providing basic intelligence, including IMINT, in the form intelligence estimates, supporting studies, and IPB analysis that describe the battlespace and threat. During course of action comparison and analysis, orders development and transition, the intelligence cycle is applied to satisfy emerging IRs and update the intelligence estimate and IPB products, all of which may be supported by IMINT. During execution the intelligence cycle is applied to implement the intelligence collection, production, and dissemination plan; refine IPB analysis, and generate mission-specific multi-discipline intelligence operations and intelligence products (including IMINT), all of which are integrated with the concept of operations. During execution, IRs are satisfied on a more individualized basis. New IRs are usually generated in response to a specific operational need. Each IR is unique and must be satisfied in a timely manner to facilitate rapid decisionmaking and the generation or maintenance of tempo (see figure 5-4).

Basic IMINT Planning Process

There are eight steps in the basic IMINT planning and execution process.

- **Planning.** The first step to receiving IMINT support is to determine that an IR exists. Exact needs are carefully determined—to include key collection, production, and dissemination requirements—so priorities can be accurately determined, resources are not overwhelmed, and timely support is received.

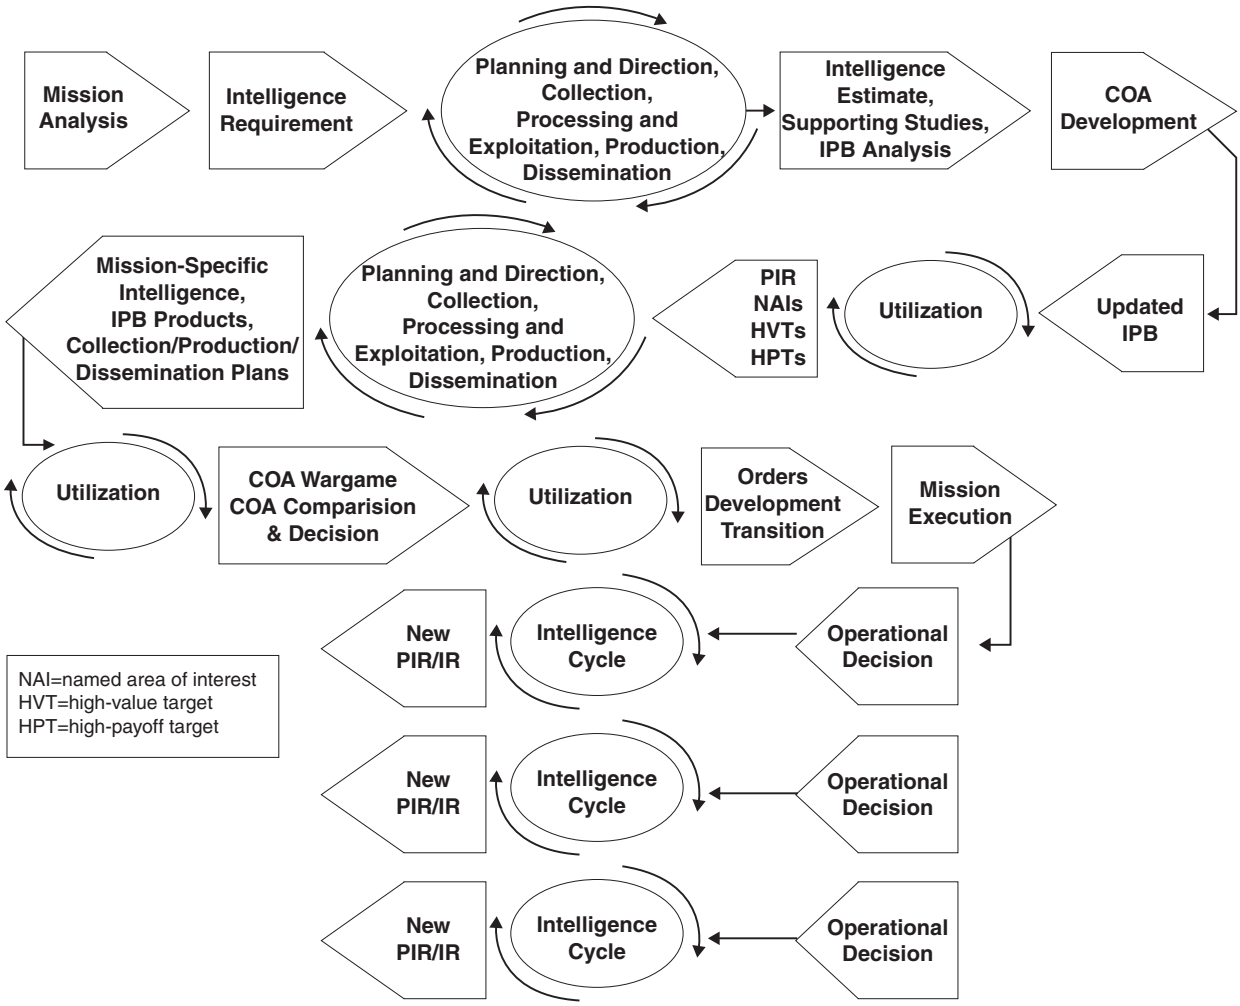

Figure 5-4. Application of the Intelligence Cycle.

- **Requesting.** The most important first step of any request is to clearly articulate IRs (to include desired imagery and other specific IMINT support). Statement of an IR should include the mission and how the intelligence product sought will get the job done.
- **Validating.** On-hand intelligence and imagery is reviewed to determine if the IR can be immediately answered. If not, it is then checked against previously validated IRs and ongoing/ planned intelligence operations to avoid unnecessary duplication. Finally, it will be checked against the capabilities of the unit's and supporting intelligence assets. If then validated, a priority will be assigned to it and associated ICRs, IPRs, and IDRs developed and prioritized.
- **Plans and Taskings.** A determination will also be made as to whether organic or external intelligence operations will be tasked to satisfy the IR. If collection is required, CMDO will determine the best intelligence asset suited to perform the mission. Concurrently, CMDO will develop plans and taskings to ensure eventual dissemination requirements can be achieved, while the P&A cell OIC will develop necessary

production plans and tasking. If organic intelligence resources will be used, appropriate orders are issued. If external support will be required, the IR will be submitted to higher headquarters or supporting organizations.

- **Collecting.** The validated ICRs and IPRs will be used to ensure the most effective type of imagery is collected to satisfy the overall IRs. The image can be recorded hardcopy or softcopy single frame or continuous (video), depending on the actual sensor. Capabilities and limitations of each imagery collection element (e.g, maximum and optimal ranges), the time the collection must occur, and the weather will influence the nature of collection operations.
- **Exploiting.** For IMINT exploitation, requirements are defined in terms of three phases of analysis, production, and reporting. Each phase represents a greater degree of analysis and a longer period of time available to accomplish the exploitation and production.
  - Phase One is the rapid exploitation of newly acquired imagery and reporting of imagery-derived intelligence and intelligence information within a specified time from receipt of imagery. This phase satisfies priority requirements of immediate need and/or identifies changes or activity of immediate significance.
  - Phase Two is the detailed exploitation of newly acquired imagery and the reporting of imagery-derived intelligence and intelligence information within the bounds of analytic requirements and timeliness of need. This phase provides an organized and comprehensive account of the intelligence or intelligence information extracted from newly acquired imagery and supported by other intelligence source materials as appropriate.
  - Phase Three is the indepth analysis of available imagery pertinent to an IR and the reporting of results within a specified time. This phase provides the most comprehensive, indepth analysis of a target or topic in response to IRs, using imagery as the primary data source but incorporating data and intelligence from other sources as appropriate.
- **Disseminating.** Imagery and IMINT products are disseminated either as hardcopy or softcopy (e.g., digital or electronic) products. Hardcopy products will go via couriers or some type of mail system. Softcopy products may also be distributed as hardcopy products (e.g., on CDs and floppy/zip disks) or electronically via the MAGTF TDN. The requestor and the supporting intelligence officers, with assistance from units' G-6/S-6s, must ensure that the requested product can be transmitted over available supporting CIS. The length of time required to receive a product electronically depends on the size of the file. Low rates of compression (e.g., 4 to 1) allow an image to be transmitted, decompressed, recompressed, and retransmitted. Higher rates of compression generally will not allow a product to be recompressed. It is recommended that if a product will be retransmitted, a copy be made before it is compressed. Once it is determined that a product meets the need of the command, the compressed copy can be transmitted without losing data.
- **Use.** The last step of the IMINT planning and execution process, as with the intelligence process, is the most important—effective utilization. Commanders and other imagery/IMINT users should quickly notify the intelligence officer as to how well the products answered their CCIRs and IRs. Additionally, new IRs that result from the new imagery/IMINT should be rapidly identified and action initiated to most effectively plan future operations. Finally, providing the intelligence officer and IMINT elements feedback will identify problems (e.g., product formats, missing or excessive information, etc.) and allow improvements to be quickly developed and implemented.

Planning Responsibilities

Intelligence Officer

Primary staff responsibility for IMINT operations planning lies with the G-2/S-2. Specific responsibilities are—

- Preparation of integrated, multi-discipline intelligence and reconnaissance operations and supporting IMINT plans, orders, annexes, and appendices.
- Coordination with the G-3/S-3 to ensure that the planned IMINT effort supports the concept of operations and scheme of maneuver, and ensures effective prioritization and integration of IMINT operations.
- Coordination with the G-6/S-6 officer for CIS support to the IMINT elements, including circuits, network access, frequency assignment, equipment, and call signs.
- Liaison with IMINT agencies and units external to the MAGTF.
- Coordination with the G-4/S-4 to ensure adequate logistics support of IMINT elements (in particular, the transportation and maintenance of IMINT units' unique and sizable equipment).

Intelligence Battalion Commander/Detachment OIC

The intel bn commander/detachment OIC is responsible to the G-2/S-2 (or the MAGTF intelligence operations officer) for the planning, direction, and execution of MAGTF IMINT operations. Specific duties include:

- Advise the G-2/S-2 on IMINT employment and its integration with other services, JTF, theater, and national IMINT operations.
- Prepare MAGTF IMINT plans and orders in conjunction with other intelligence section staff officers and key intel bn subordinates (e.g., IIP platoon commander).
- Plan, supervise, and assist IMINT collection requirements and taskings for MAGTF operations in conjunction with the collection management officer.
- Coordinate the movement, operation, and reporting of IMINT units in coordination with the SARC OIC and the G-3/S-3.
- Coordinate MAGTF all-source fusion center (AFC) analyst exchanges with IMINT analysts, and the integration of imagery and IMINT products with all-source intelligence production in conjunction with MAGTF AFC OIC.
- Plan for the timely reporting of IMINT-derived intelligence to MAGTF and external elements and the rapid handling of perishable IMINT information in coordination with the dissemination officer.
- Plan and coordinate IMINT communications paths and information systems management and operations in conjunction with the G-6/S-6.

General Planning Considerations

Principles

Provide Imagery and IMINT to Meet Requirements

The IMINT plan must ensure imagery data is collected, processed, and reported to satisfy the IRs set forth in the commander's guidance and collection plan. Particular attention must be paid to the timeliness and formats of the data provided.

IMINT Operations Must be Integrated with Operations

The IMINT plan must take into account the location and activities of the supported units. Planned missions must be scheduled where and when they can best collect sensor data, and C2 and CIS arrangements coordinated ensuring imagery data and IMINT reports are reported to the supported units. Enemy activity may be anticipated at certain

phases of the operation; IMINT operations and analytical personnel must have a situational awareness of both intelligence estimates and ongoing operations to focus their efforts at a particular time and area. Finally, the requirement for timeliness in processing and reporting may vary depending upon the stage of the operation; personnel must be aware of current timeliness requirements as well as the availability of CIS resources with all supported commands.

Provide Redundancy in the Intelligence Plan

The IMINT plan must be integrated with other intelligence and reconnaissance operations to ensure that the needed data can still be acquired even if a planned imagery mission is canceled or if equipment malfunctions occur. The ability to provide this redundancy is dependent upon a number of factors, primarily the number of imagery missions available, capability of other intelligence resources to acquire the information needed, and the availability of production resources.

Make Full Use of All IMINT Resources

While some imagery collection resources may be held in reserve, most such units and systems can fulfill multiple missions and thus will likely be employed (e.g., ATARS). Close coordination and integration of operations and intelligence activities will aid with identifying and prioritizing such multi-purpose missions. IMINT production resources are not held in reserve.

Concept of Operations

The IMINT effort must support and adapt to the MAGTF commander's intent, concepts of intelligence and operations, and the supporting scheme of maneuver. Key questions to answer include:

- What is the MAGTF AO and the area of interest (AOI)?
- What is the MAGTF concept of operations, task organization, and main and supporting efforts?
- What are the standing PIR and IRs? Which have been tasked to supporting IMINT units? What specific information is the commander most interested (e.g., enemy ground operations, enemy air operations, target BDA, friendly force protection or enemy future intentions)?
- What is the concept of MAGTF fires support? How will MAGTF target development and target intelligence be conducted? What are the specific imagery needs in support of these?
- What are the IMINT and intelligence concepts of operations of other JTF, component, and theater resources? What is the task-organization and command/support relationships for all MAGTF intelligence and reconnaissance units?
- How can Navy IMINT assets and other Services, JTF, theater, and national IMINT assets be employed and integrated to support MAGTF operations?

Terrain

Terrain factors have a significant impact on IMINT operations; such as the ability of IMINT sensors to see through vegetation and IMINT's requirements for line-of-sight (LOS) communications. All IMINT collection systems require LOS with the target area to be effective. Accordingly, IMINT planners must assess the effects of mountains, defilade, vegetation, and other potential terrain obstacles on planned IMINT operations.

Weather

Weather is a key limiting factor for IMINT operations. Bad weather degrades the identification and location of targets. Weather can also limit the type of imagery collection capabilities that may be employed. Finally, low ceilings and poor visibility decreases visual reconnaissance effectiveness as well as the resolution of photographic systems.

Precipitation

Visible moisture degrades optical and visual reconnaissance systems. A UAV is not an all-weather

aircraft. Exposure to rain, ice, and snow can severely damage or destroy a UAV.

Wind

UAVs, due to their lighter weight, are significantly more affected by wind than manned aircraft. The Pioneer UAV has a crosswind limitation of 16 knots for takeoff and landing and a total wind component limitation of 30 knots in flight. The UAV currently under development will have a crosswind limitation of 25 knots and a total wind component limitation of 30 knots in flight.

Clouds, Haze, and Smoke

In addition to affecting an aircrew's ability to conduct visual reconnaissance, these conditions also affect EO and infrared systems in manned aircraft and UAVs.

Daylight, Sun Angles, and Shadows

The angle of the sun affects visual, TV, and FLIR observation in varying degrees. The quality of FLIR imaging decreases as the sun rises and reaches a point where a target can be seen visually. At this point the target cannot be detected by a FLIR. Prior to sunset and just after sunrise, long shadows are cast by large terrain features and can obscure objects in their path. The ideal time to take photographs or observe a target is midmorning or midafternoon. During these periods, shadows are cast long enough to add definition and dimension to a target.

Threat

General

Detailed threat analysis must be conducted to determine which IMINT sensors and platforms can be employed effectively against a given enemy and how to employ limited MAGTF and external resources to obtain the best possible IMINT. Imagery operations can be hampered by the enemy's air defense capability and its camouflage, cover, concealment, and deception activities.

Aviation-Related

Enemy air defenses have a direct effect on aerial imagery collection missions. Significant antiaircraft artillery (AAA) and surface-to-air missile (SAM) threats may degrade visual reconnaissance due to a need for aircraft to stay beyond threat air defense ranges. IMINT planners must assess threat air defense and air-to-air threats when evaluating risk and determining routes. Because of a UAV's slow speed, AAA is its greatest threat, while SAMs pose greater risks to MAGTF fixed-wing aircraft. Finally, threat electronic warfare capabilities must be determined to assess their effects on UAV and manned imagery platforms radio uplinks and imagery downlinks.

Specific Planning Considerations and Execution Activities

Planning and Direction

Objectives

IMINT planning is a continuous function that requires close interaction between the G-2/S-2 and IMINT unit planners. Key objectives include:

- Identify IMINT requirements.
- Prepare IMINT operations plan.
- Plan and establish the IMINT support system (CIS, logistics, etc.).
- Issue orders/tasking to IMINT units.
- Supervise and coordinate IMINT operations.

Key Considerations

Effective IMINT planning and execution require close coordination, liaison, and integration with all-source intelligence elements. IMINT collection management often will be driven by tip-offs (or cueing) from SIGINT, HUMINT, and other sources of intelligence. Also, fusion of IMINT with other intelligence ultimately drives the conduct of future IMINT operations and the development of IMINT products. Related concerns include:

- **Split-basing.** IMINT operations favorably lend themselves to using a split-basing concept of operations and should be considered for many deployment situations. CIS connectivity, bandwidth availability, and equipment and combat service support requirements are key factors in determining the IMINT concept of operations that must be considered.
- **Liaison elements.** Identifying, preparing, and locating IMINT or all-source intelligence liaison elements to support MAGTF IMINT operations is a critical early planning action. IMINT liaison teams will be small in number due to limited availability of imagery personnel. Placing IMINT liaison elements where they can coordinate operational planning and providing them necessary CIS support are the keys (e.g., IMINT liaisons with JTF collection and ATO planners).
- **Physical demands.** IMINT planners must take into account the strenuous mental and physical demands (especially visual) on imagery analysts during sustained operations, particularly when planning watch schedules for imagery analysts performing detailed imagery exploitation tasks. Additional IMINT planning considerations for specific type MAGTF operations include:
  - **Expeditionary operations.** Multispectral imagery, hyperspectral imagery, and other new special imagery capabilities can provide unique support to ship-to-objective maneuver (STOM) operations, such as in the detection of sandbars and obstacles in the water.
  - **Peacekeeping and humanitarian assistance operations.** National imagery usually provides the initial baseline to support planning for peacekeeping and humanitarian assistance operations. The typical multinational nature of these operations, however, leads to critical planning and dissemination requirements. National imagery is not releasable to most multi-national partners without prior approval from NIMA. Each type imagery has specific requirements (e.g., waivers are often given for EO imagery dissemination).

Collection

A variety of organic imagery collection capabilities is available to a MAGTF (see figure 5-5). The following planning considerations are critical to effective direction and employment of these resources.

General Imagery Collection Planning Considerations

Imagery collection resources have excellent capabilities to locate and identify major threat forces, moving vehicles, weapons systems, structures and other topographic features contrasting with their surroundings. Conversely, it can be difficult to locate small, stationary and/or well-camouflaged enemy forces blending in with their surroundings. Generally it is better to employ imagery collection resources against point targets, vice in a wide area search mode. Effective integration with other intelligence operations can cue imagery collectors against key targets, reducing the general search area and more rapidly producing useful intelligence. Some basic imagery collection planning considerations follow.

Area Reconnaissance Imagery Collection. Area reconnaissance is the systematic and complete coverage of an area using visual and/or imaging means. Area reconnaissance is normally conducted for locating and identifying potential targets for further analysis or in support of terrain analysis. Area reconnaissance imagery is accomplished in one of two ways:

- By imaging back and forth across a predetermined area in such a way that the flight lines and individual images overlap. This provides complete stereographic coverage of all objects within the area at the expense of increased sensor utilization time.
- By adjusting focal lengths and/or altitudes to allow a lesser number of images to cover the target area. This reduces TOT as well as the

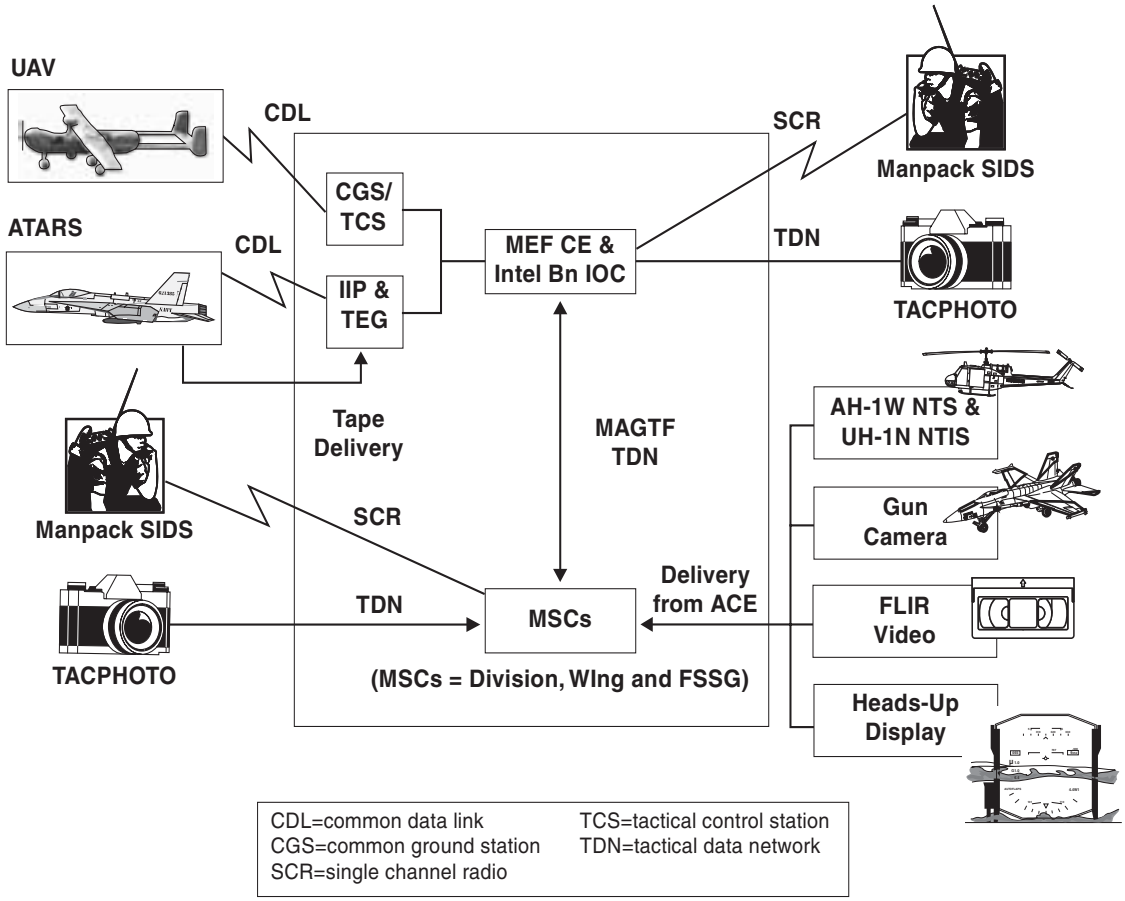

Figure 5-5. MEF Imagery Collection Capabilities.

processing, exploitation, and dissemination time at the expense of reduced resolution.

Types of area reconnaissance imagery missions include:

- BAC and BAS are area reconnaissance imagery collection tactics that are good for providing an overview of an entire area. During the early phases of an operation, these may be done for two intelligence purposes: providing a basis for the procurement of larger scale imagery of selected areas for subsequent detailed analysis; or to serve as a comparative baseline for determining the nature and extent of changes identified on subsequent missions. BAC and BAS should not be used to hunt for OOB information, as exploitation of these is very manpower and time intensive. During such area collection operations, the flight tracks (or routes) are planned and the image exposures adjusted so that each successive image will overlap the previous one.
- DSA missions provide focus and detail and are useful for OOB confirmation counts.

Point Reconnaissance Imagery Targets. Point reconnaissance imagery target (also called pinpoint reconnaissance) is a small area. While sizes may vary, at the tactical levels (e.g., MSE and below command echelons) this area is usually not larger than one kilometer by one kilometer, while at the MAGTF CE/operational level this area will generally be of 10 nautical

miles or less. Point reconnaissance missions are normally tasked to provide the highest resolution possible of a specific target to allow for detailed analysis. A command post, bridge, airfield or SAM site would be considered point targets.

Route Reconnaissance Imagery. Route reconnaissance imagery is simply imaging along specific transportation routes such as roads, railroads or waterways. This type of reconnaissance is normally conducted to determine enemy movement, to determine usability of the route, or in support of GEOINT mapping or terrain analysis requirements. This tactic is good for LOC and maneuverability studies, but generally requires significant time for effective exploitation. Route reconnaissance imagery missions should be done as a contingency baseline, ahead of time. This coverage is typically done by one or two collectors flying at a low altitude along a specified route.

Strip Search Reconnaissance Imagery. Strip search reconnaissance missions are similar to the route reconnaissance except that the collector will fly in a straight line from one point to another or along predetermined flight paths not necessarily related to transportation routes. This type of mission is frequently conducted using oblique or side-looking sensors to monitor activity across enemy lines or demilitarized zones, while allowing the aircraft to fly over friendly territory.

Aerial imagery collectors provide the flexibility to respond rapidly to changing battlespace conditions. UAVs offer the added advantage of operating in areas of heavier enemy air defenses and providing the needed intelligence without the risk of exposure of manned aircraft. Using the results of IPB and the MAGTF's concept of operations and scheme of maneuver, intelligence imagery collection planners will generally establish detailed preplanned imagery collection routes, areas, and point targets encompassing the AOI to streamline intelligence and operational planning.

In addition to the intelligence planning considerations, such missions require detailed operational planning, particularly regarding their integration with other ACE operations. As all aerial imagery collection platforms are multipurpose, close coordination between MAGTF CE imagery planners and ACE operational planners is necessary to identify, reconcile, prioritize, and integrate competing requirements for these resources. Additionally, all aerial imagery missions must be included on the ATO and coordinated with other air operations and, where pertinent, supporting arms. This is particularly critical regarding UAV operations. UAVs enter the airspace control system via the appropriate airspace control agency, normally the direct air support center (DASC). UAV controllers maintain communications with the appropriate ACE C2 agency (e.g., the DASC) during missions to receive routing, altitude, and other pertinent airspace control information.

The commander who directly tasks or controls an imagery collection mission will receive the most responsive support. The responsiveness of the mission to other commanders depends on the number of echelons through which the mission request and resulting intelligence must flow. Accordingly, when planning imagery collection operations, the advantages and disadvantages of dedicating missions to a single command (i.e., direct support) must be assessed against the MAGTF's total IRs and the current situation.

Previously acquired imagery and IMINT products should always be reviewed to see if they can satisfy IRs without need of additional imagery collection missions.

Often the intelligence acquired from an imagery collection mission (vice the actual image itself) will be all that is required to satisfy many IRs. Likewise, dissemination challenges are generally simpler and faster when users' IRs can be satisfied without the images. Accordingly, commanders must understand the pros and cons of various imagery-related IRs to ensure optimum support.

Usually collected imagery will require additional processing and fusing with other intelligence to provide the necessary support. Depending on the situation, this may be a time-intensive task. Commanders should assess likely processing and production times and other requirements when developing IMINT plans.

Intelligence acquired from a number of imagery collectors may be disseminated directly to users with minimal additional intelligence processing and all-source intelligence analysis. Supporting dissemination plans must ensure identification of the type products likely disseminated and, the technical requirements associated with these. In the case of resources such as the UAV or JSTARS, dissemination planning includes the establishment of dedicated communications links directly between the collector and the supported unit (e.g., by assigning a UAV RRS detachment with organic communications to the supported unit's command echelon).

Types of Imagery

Vertical Imagery. Vertical imagery coverage of a target is obtained by direct overhead photography (see figure 5-6). It provides imagery of a relatively constant scale. It also allows the imagery analyst to achieve optimum results from stereovision and to accomplish the most accurate measurements. Stereovision is the effect obtained when overlapping photographs are viewed with the aid of special optical equipment, enabling height and slope determinations, as well as other detail not visible to the naked eye. Figure 5-7, on page 5-14, is an example of a vertical image.

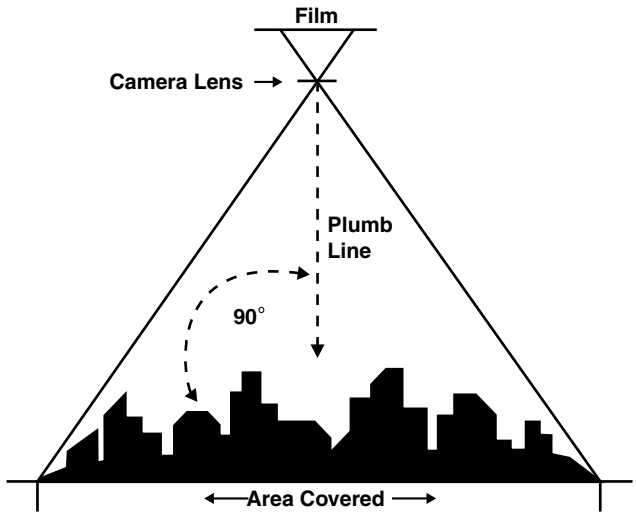

Figure 5-6. Vertical Imagery.

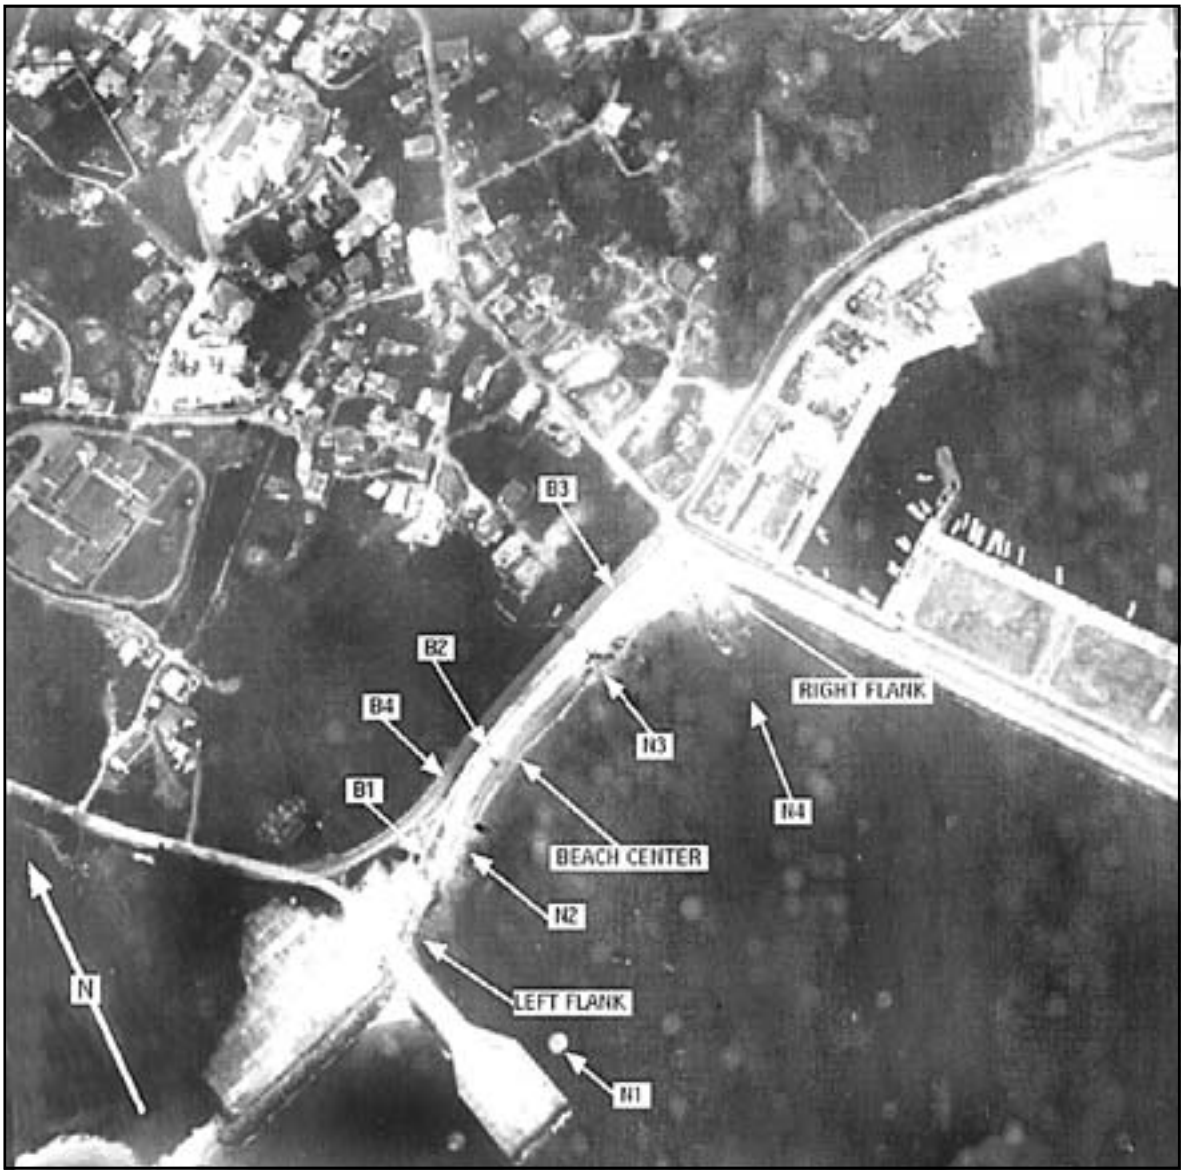

Figure 5-7. Vertical Imagery Example.

Oblique Imagery. Oblique imagery coverage is obtained by imagery taken at an angle from the vertical. High oblique imagery includes the horizon and has a large ground coverage (see figure 5-8); low oblique imagery does not include

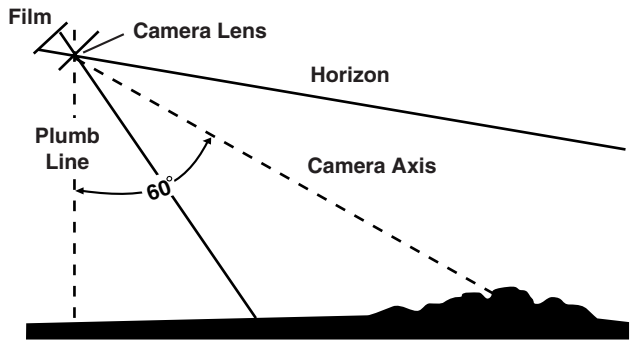

Figure 5-8. High Oblique Imagery.

the horizon and has a small ground coverage (see figure 5-9). Oblique imagery provides a representation of the target comparable to flying towards or parallel to it. It closely resembles a normal eye view and allows the imagery analyst to see into an area in a normal fashion. Measurements of oblique imagery are more difficult than with vertical imagery since the scale is not constant across the image, and precise subject distances cannot be determined. An operational advantage to such imagery, however, is the possible increased survivability it offers to manned and unmanned aircraft.

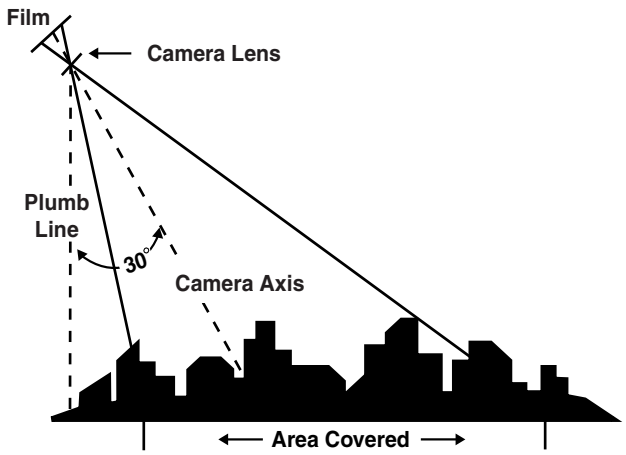

Figure 5-9. Low Oblique Imagery.

Panoramic Imagery. Panoramic imagery scans a wide area. Generally it is categorized according to the altitude at which the mission is flown and the angle of the scan. Low panoramic imagery is taken at low altitudes and scans a wide area, including the horizon on either side of the collector's flight line (see figure 5-10). High panoramic imagery is taken from higher altitudes with a smaller scan angle; generally the horizon is not visible on the image (see figures 5-11 and 5-12). This type of imagery can be useful when only one collection pass over the target area is possible as it provides coverage of

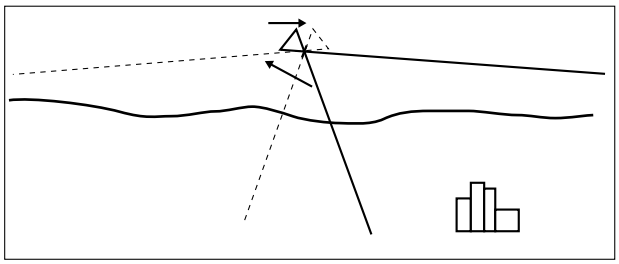

Figure 5-10. Low Panoramic Imagery.

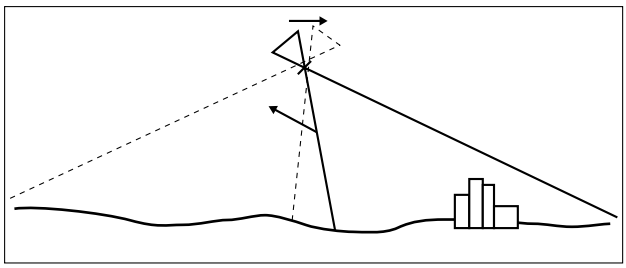

Figure 5-11. High Panoramic Imagery.

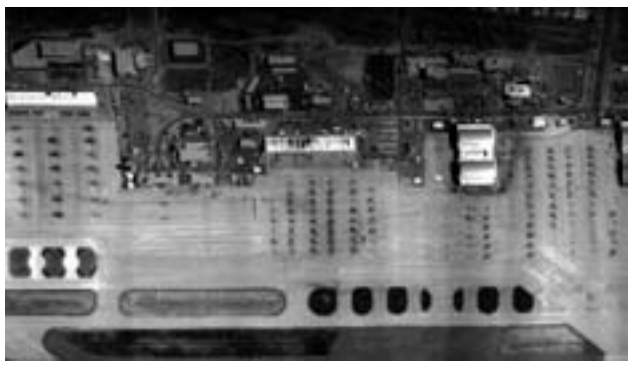

Figure 5-12. Panoramic Imagery Example.

large areas on both sides of the flight path. It is, however, more difficult and time-consuming to analyze and measure owing to the distortion of the recorded image.

Infrared Imagery. Infrared imagery is the remote sensing of a target's radiant temperatures. The system is used to measure the temperature differences between terrain features and surrounding objects on the ground, producing a near-optical quality infrared image (see figure 5-13).

Figure 5-13. Infrared Imagery Example.

These systems can operate during either day or night and under all weather conditions. However, they are less effective during day/night transition periods or when backgrounds and targets have the least difference in temperature. Also, infrared imagery uses temperature differential to generate the image so anything that degrades infrared transmission will impact the imagery.

Infrared imagery complements photographic imagery by day, and they are commonly used together. Unique infrared imagery capabilities include imaging the shadow on a heat-absorbing surface or the thermal scar of a heat-generating object (e.g., aircraft after it has moved).

Radar Imagery. As a radar can penetrate virtually all atmospheric conditions, radar imagery generally is limited only by the capability of the platforms conducting the collection mission. Radar operates on two principles: all materials reflect a portion of electromagnetic radiation; and electromagnetic energy is directed in a beam from the antenna to the target area. It is then reflected by the target back to the collecting platform. Variations in pattern and tone of the returned pulses are recorded and displayed as radar images. Figure 5-14 is an example of JSTARS SAR imagery. The geometry and surface composition of targets and their surroundings can greatly affect the intensity of the radar pulse return. To detect moving targets, radars employ the principle of doppler shift. Doppler shift is the result of a moving object causing a subtle change in the frequency of the reflected pulse energy. This change is detected by comparing the original pulse energy frequency to the frequency of the reflected energy. Advantages of radar imagery include its superb capabilities over great distances under a wide variety of conditions; it provides great operational flexibility, particularly during mid to higher intensity combat

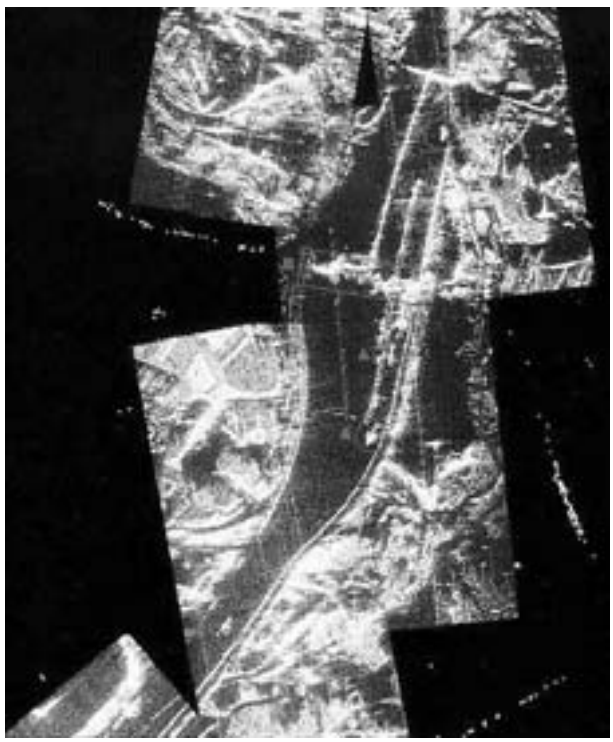

Figure 5-14. JSTARS Synthetic Aperature Radar Imagery Example.

operations; and it provides constant scale. However, radar imagery is not useful as a stand-alone intelligence product. Unlike optical imagery, it presents an abnormal view of the battlespace, requiring special skills and time to analyze properly. (See figure 5-15 for an example of an MTI image.)

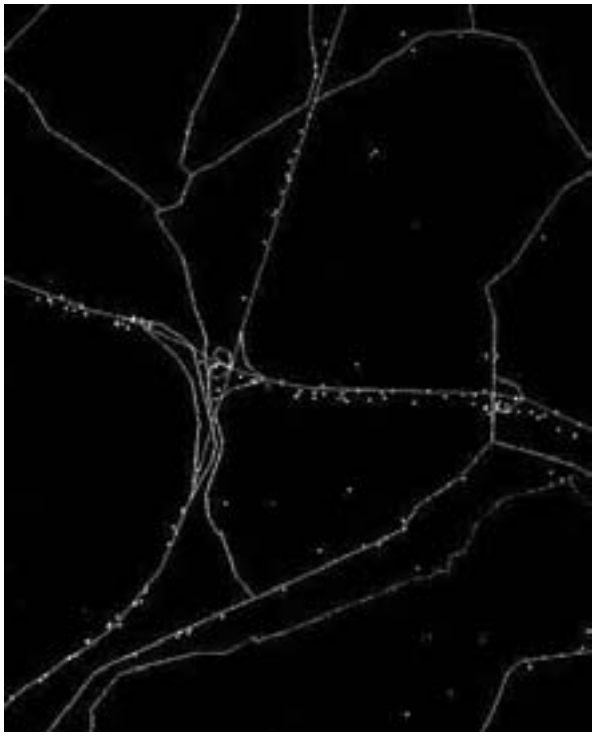

Figure 5-15. JSTARS Moving Target Indicator Imagery Example.

Electroptical Imagery. EO imagery employs digital imaging techniques to extend and complement other imagery. Advantages include the dynamic range of the sensor generally is greater than other types of imagery; it can penetrate atmospheric conditions that are opaque to other sensors; and, like radar imagery, EO imagery is readily exploitable by automated processors and analytical aids. EO uses the visual spectrum, so anything that impacts this (dust, smoke, haze, clouds, rain, fog, light level, angle of illumination, etc.) will affect the quality of the imagery.

Multispectral Imagery. Multispectral imagery (MSI) records views in a number of spectral bands or frequencies simultaneously, providing a wider range of processing and analytical techniques to be employed. The key to interpretation lies in identifying the spectral signatures of different surfaces and targets. Every surface or target gives off its own distinctive pattern of radiation, whether it is generated by itself or reflected. This will depend on its reflective qualities, its heat, whether it is a solid or liquid, how smooth its surface is, and many other factors. MSI usually has less resolution in the visible spectrum but can reveal details not apparent on the latter. This allows MSI the capability of providing map-like products to support area familiarization and orientation. Unlike other types of imagery, most MSI products are acquired from commercial sources. NIMA is responsible for purchasing, archiving, and disseminating MSI products for DOD.

Commercial Imagery. The commercial imagery industry is planning the launch of several new high resolution visible, MSI, and other imagery systems within the next 5 years. These systems will provide an increased capability to supplement and complement our national imagery technical collection. HQMC Imagery and Geospatial Plans and Policy works closely with NIMA on numerous commercial imagery issues. Marine Corps policies and procedures for requesting, tracking, obtaining, and purchasing commercial imagery are being developed and will be promulgated once NIMA's Commercial Imagery Management Office (CIMO) develops a commercial imagery plan to provide better DOD and intelligence community access to commercial imagery.

Domestic Imagery Collection. Domestic imagery collection is satellite and aerial imagery of any part of the US, its territories or its possessions, including the 12 nautical miles seaward of these land areas. A Proper Use Statement and approval are required before domestic imagery collection may be conducted. Central to this process is a thorough review of planned missions to ensure that the constitutional rights of US persons are protected in accordance with current laws and executive orders that restrict intelligence activities directed against US persons within the US. Once approval has been

obtained, proper use statements must be retained in the permanent files of the requesting unit and higher headquarters up through the combatant command headquarters. (See the NIMA Imagery Policy Series [section 9, part B], *Domestic Imagery* [IPS-001/98-S9A] for additional information on domestic imagery collection.) Request channels for domestic imagery collection are:

- **Marine Corps specific requirements.** Proper use statements are submitted via the service chain of command to HQMC Imagery and Geospatial Plans and Policy.
- **Joint operations requirements.** Proper use statements are submitted via the operational chain of command to combatant commander for adjudication or follow-on action as appropriate.

Aerial Imagery Collection Missions

Preplanned Missions. Preplanned aerial imagery missions (UAVs, ATARS, JSTARS) are requested using the joint tactical air reconnaissance/surveillance request (JTAR/SR) format (see appendix C, section I). Within the MAGTF, preplanned aerial imagery requests are routed through the intelligence chain and consolidated by the MAGTF CE's intelligence section for validation, prioritization, and follow-on planning and coordination. Once a decision is made to conduct an aerial imagery collection mission, the G-2/S-2 concurrently will: refine the JTAR/SR as required and submit it to the G-3/S-3 for follow-on planning and integration within the MAGTF and/or JTF ATO; and, plan and coordinate supporting intelligence production and dissemination plans. Key planning information included on JTAR/SRs are—

- Date-time factors: dates and time on targets desired and latest time desired intelligence will be of value (LTIOV).
- Type intelligence collection mission. (It is emphasized that the same request and planning process is used not only for aerial imagery collection missions, but also for aerial electronic intelligence/electronic warfare support missions and aerial visual reconnaissance missions.)
- Target, route or area coordinates.
- Target categories and associated PIR.
- Type intelligence products desired (i.e., reports and photos or reports only).
- Units to whom the resulting intelligence products will be disseminated.

The long lead time required for JTAR/SR submission needed by ACE operations planners is not often conducive to effective intelligence and IMINT planning. Therefore, effective standing operating procedures (SOPs) must be developed between G-2/S-2 and ATO planners to both meet air operations deadlines and strive to accommodate the intelligence planning aspects of rapidly changing situations. One method that may be used by intelligence planners is to initially provide ATO planners the most comprehensive JTAR/S request possible (i.e., specify desired aerial imagery platforms, type of imagery mission, targets, and anticipated IRs). At a designated time (i.e., no later than 6 hours prior to mission start), imagery planners will provide ATO and imagery collection units with the final detailed intelligence tasking information for each mission-detailed target point/route/area location information, specific IRs, and final C2, reporting criteria and CIS channels to be used.

Immediate Missions. Immediate requests for aerial imagery collection may be submitted directly to the DASC. However, as available resources are generally limited and operating in general support of MAGTF requirements, approval from the mission's controlling intelligence officer must be obtained prior to diverting an aerial imagery platform from a preplanned mission.

The joint tactical air strike request format shown in appendix C, section II, may be used to request immediate aerial imagery collection support. If approved, the mission may be executed in one of the following ways:

- An ongoing mission can be diverted by its controlling authority to conduct the immediate mission.
- An on-call/standby mission may be allocated.

Air Planning and the Air Tasking Cycle. Whether for preplanned or immediate air missions, the air tasking cycle is the key tool used by MAGTF planners to most effectively plan air operations to support mission accomplishment. It is an integral part of the MAGTF planning process. By using and completing the tasking cycle, planners can ensure that limited aviation assets are used to achieve their maximum effect with correct prioritization, C2 and CIS in support of the MAGTF's main and other key efforts. The principal planning product of the air tasking cycle is the MAGTF ATO or air plan. The six phases of the ATO cycle are command aviation guidance, target/air support mission development, allocation and allotment, tasking, force execution, and combat assessment (see figure 5-16).

The ATO is a document generated by the JFACC or the ACE commander. It tasks and disseminates to JTF components, subordinate units, and C2 agencies the specific missions and targets of projected air sorties, capabilities, and forces. It normally provides both general instructions and specific instructions, including call signs, targets, and controlling agencies. The airspace control order is included in the ATO. Special instructions, providing amplifying notes, important details, and changes are included in the ATO or issued separately. The ATO, airspace control order, and special instructions provide operational and tactical direction at appropriate levels of detail.

Each ATO covers a 24-hour period. There are usually three ATOs at any given time:

- The ATO in execution (today's plan), monitored by the ACE current operations staff.
- The ATO in production (tomorrow's plan).
- The ATO in planning (the following day's plan) by the ACE future operations planners.

Because input to the joint ATO must be provided 3 to 4 days in advance, the ATO can represent only a starting point for daily MAGTF flight operations. It is impractical to predict every need in advance. The MAGTF commander must have the flexibility to launch or to divert any aircraft as necessary to complete the mission, even if this requires short-notice deviations from the ATO.

In accordance with maneuver warfare, the ATO must be flexible enough to change with the needs of the force as the situation changes. It is not a

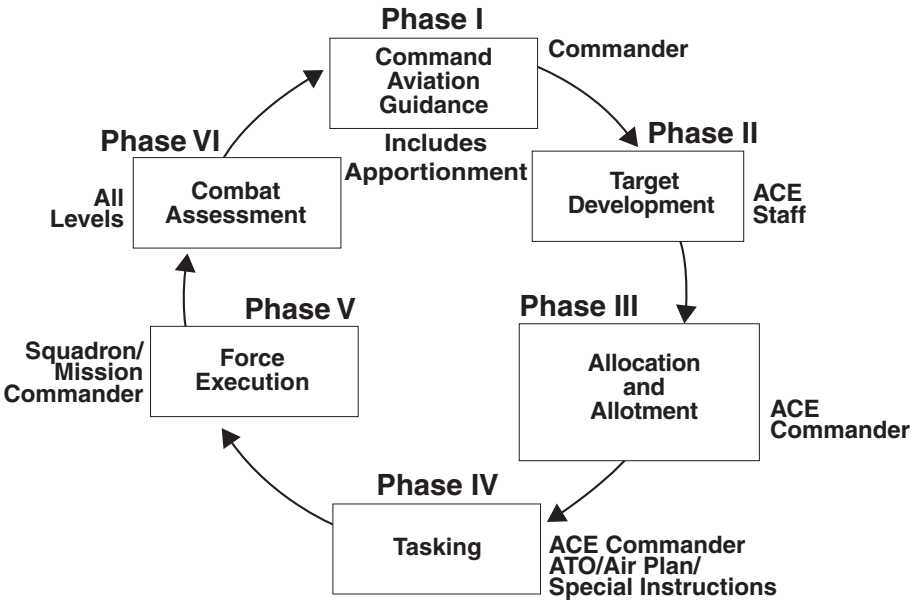

Figure 5-16. The Six-Phase Aviation Tasking Cycle.

rigid constraint on operational flexibility. Because the ATO represents a great deal of necessary coordination and deconfliction of air assets and airspace, however, necessary deviations from the ATO should be well-justified and relevant. Headquarters should be informed as quickly and as fully as possible. The process by which changes are made to the ATO is directed by the JFC.

During purely Navy/Marine Corps operations afloat, there may be no ATO as such. All squadron flight schedules are consolidated with the needs of the MAGTF/ship/amphibious ready group (ARG)/carrier battle group (CVBG) at an air board. The air board meets every day in the supporting arms coordination center (SACC). It works on current and future plans for air support. The results are published as the ship/ARG/CVBG air plan. The air board also provides the input for the joint ATO. Generally the MAGTF intelligence section will have a representative from its future plans section or intel bn's CMD section at all air board meetings to coordinate aerial imagery and other air intelligence mission needs.

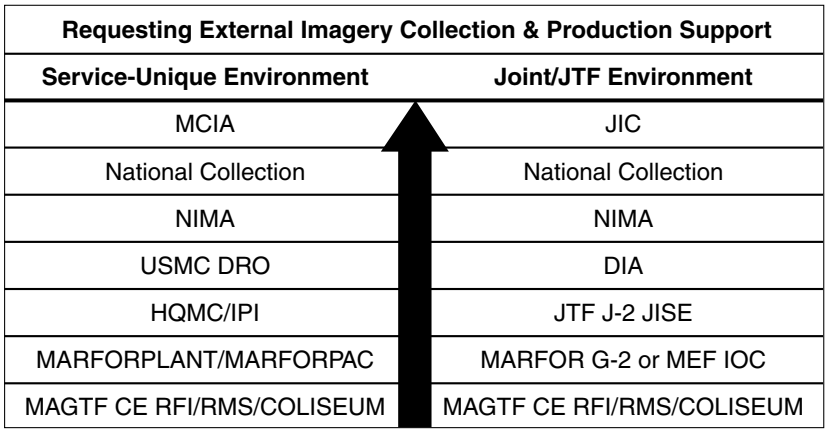
Not every mission on squadron flight schedules and air plans will appear on the joint ATO. Flights that are within the MAGTF's airspace and made in support of the MAGTF; e.g., not in support of the JTF, may or may not be included in the joint ATO. Such flights are mostly helicopter flights and functional check flights. Such flights may include tactical missions generated to respond to the changing battlespace situations. Often, ships (particularly aircraft carriers) may operate outside of the JTF's airspace entirely. In such cases, missions that do not enter JTF airspace will not appear on the joint ATO. Nonetheless, every mission that is submitted and approved for the joint ATO must appear on squadron flight schedules and the MAGTF/ship/ARG/CVBG air plan.

Requesting JTF, Theater and National Imagery Support. Significant imagery and IMINT support is available to the MAGTF from external sources ranging from dissemination of existing imagery and products through the integration of existing information into new products and execution of new imagery collection and IMINT production. MAGTF IRs that cannot be satisfied via organic resources will be submitted to the next higher command echelon for validation, prioritization and, if possible, satisfying the request for intelligence or collection requirements through its organic resources before forwarding it to the next higher command echelon. The specific IR will determine how the requirement is identified and submitted. Techniques range from use of the standard request for information format, using the RMS resources and procedures (for new imagery collection requirements) or using COLISEUM resources and procedures (for IMINT or all-source production requirements). Figure 5-17 identifies the two different tracks external imagery and IMINT requirements may take.

Processing and Exploitation

Processing and exploitation involve the conversion of collected data into information that is suitable for the production of intelligence. Processing is largely a technical function that does not add meaning to the data, but instead is necessary to convert the data into a form that commanders and planners can understand (e.g., developing a piece of film into a usable image). Some types of data require minimal processing—they may be collected in a form that is already suitable for production. Other types of data require extensive processing to incorporate amplifying data not available on the raw image products, affecting the timeliness and accuracy of the resulting information.

The degree of automated processing resident in IMINT resources varies. For example, the video downlink from a UAV can provide the geographical coordinates of acquired targets—but only to select C2 nodes. Likewise, the JSTARS CGS is capable of automatically processing, storing, and displaying acquired MTI, FTI, and SAR imagery. Usually acquired imagery requires additional processing and exploitation before it is usable. This processing and



Requests for national-level imagery collection and IMINT production take one of two tracks: via peacetime service-unique channels (e.g., exercises, planning); or via joint/operational channels for actual operations.

Figure 5-17. Requesting External Imagery and IMINT Support.

exploitation of imagery data into IMINT is accomplished by the IIP or MCIA imagery analysts or by CGS personnel. They refine raw imagery into clear and usable imagery products by using manipulation tools available at their workstations (e.g., annotation of images, immediate identification of key pieces of threat equipment, measurement of a structure's dimensions). Situational factors and standing IRs will be assessed to determine to what degree such products may be immediately disseminated or whether additional intelligence analysis is required.

Production

Production is the activity that converts information into intelligence. It fuses new information and existing intelligence from all sources to provide meaningful knowledge that can be used for decisionmaking. Production involves the evaluation, interpretation, integration, analysis, and synthesis of all information that is relevant to a particular IR to answer the question(s) that have been asked.

The results of exploited and analyzed imagery and imagery data form the basis for IMINT reports and derived products provided to the G-2/S-2 for the further production and analysis of all-source intelligence, directly to tactical commanders and to other users. User needs will rarely be fully satisfied simply via uninterpreted image prints. Instead, IMINT production planning and management will be closely coordinated with all-source intelligence production management and planning to determine the scope, content, and format for each product; to plan and schedule the development of products; to assign priorities among the various IMINT product requirements; to determine who needs what products and in what quantities; to allocate IMINT processing, exploitation, and production resources; and to coordinate production efforts with IMINT and all-source collection and dissemination activities. The goal is effective and efficient use of limited resources while ensuring that IMINT production is focused on validated PIRs and IRs and associated specified intelligence reporting criteria.

IMINT production can range from the preparation of highly sophisticated multimedia products to the selection of suitable imagery forms for either stand-alone use or for integration and fusing within all-source intelligence products.

A wide variety of IMINT products may be developed, either as stand-alone, single source products or as part of all-source intelligence products: annotated prints, mosaics, oblique panoramas, supporting detailed IMINT, and all-source intelligence text reports.

Imagery Graphic Products

Imagery graphic products of objective areas (target areas, beaches, helicopter landing zones, etc.) are useful for a variety of planning and decision-making activities. Such products include:

- **Photographic prints.** A photographic print represents a single frame of imagery from a mission. Photographs often portray an idea more rapidly and concisely than words. For this reason, prints can provide a picture of significant items of interest to users in addition to any written reports. Prints will usually be annotated in some fashion to emphasize significant military information. Minimum annotations usually will be a titling strip, to include a grid reference or geographic coordinates for the illustrated target(s) and the date-time-group of the imagery, and a north arrow or other orientation aid to help with orienting the print to a map. Other annotations may include target categories and descriptions.
- **Mosaics.** A photographic mosaic is a combination of two or more overlapping prints that form a single picture. Mosaics can be of significant value in providing an updated picture of a large area to supplement map data. Usually vertical photographs are used and produce "map-like" results, but oblique photographs may be used to produce a panorama. Mosaics supplement map data and text intelligence reports by displaying current information on roads, trails, built-up areas, and the conditions of terrain and vegetation.

IMINT Text Products

Commander's timeliness requirements will drive the type and preparation of each of the below IMINT text products. (Appendix F provides the formats and instructions for the following IMINT reports).

- **Reconnaissance Exploitation Report (RECCEXREP).** The RECCEXREP is used to report the results from the first rapid analysis of imagery, to include the debriefing of the aircrew when possible. It addresses those targets requested in the original imagery collection mission tasking, normally with each target addressed separately. It is prepared by the IIP (with input from the supporting collecting unit's intelligence section) and disseminated in accordance with the dissemination plan. The specified time limit in which the RECCEXREP must be completed and disseminated will be per unit SOP.
- **Initial Photographic Interpretation Report (IPIR).** The IPIR provides information on tasked imagery collection missions not previously reported (e.g., in the RECCEXREP) when extensive or detailed data from a systematic review of the imagery is required or if the rapid response required by the RECCEXREP would be hindered by the format, size or quality of the imagery involved. It also is prepared by the IIP (with input from the supporting collecting unit's intelligence section) and disseminated in accordance with the dissemination plan. The specified time limit in which the IPIR must be completed and disseminated will be per unit SOP.
- **Supplemental Photographic Interpretation Report (SUPIR).** The SUPIR provides information not previously included in a RECCEXREP or IPIR. It reports on significant targets covered by the mission and other required supplemental data. It is prepared by the IIP (with input from the supporting collecting unit's intelligence section) and disseminated in accordance with the dissemination plan. Generally, the unit SOP specifies the time limit for completing and disseminating the SUPIR.
- **SALUTE Report.** The standard SALUTE (size, activity, location, unit, time, equipment) report is used to report any known or suspected enemy activity. It may also report any characteristics of the area of operations that affect mission accomplishment. The SALUTE report

may be used by UAV squadron, ground reconnaissance, aircrew or other personnel to report key information obtained during ongoing imagery collection operations. It will be disseminated in accordance with the dissemination plan—generally from the collector to the SARC or directly from the collector to other supported units.

IMINT Support to Other All-Source Intelligence Products

Imagery alone will provide useful intelligence to commanders and planners. See appendix G for detailed information regarding imagery and IMINT support to IPB and other all-source intelligence products.

Usually IRs will be satisfied more effectively and in greater detail via the complementary combination of an image and supporting IMINT or all-source intelligence products. Review appendix H for an appreciation of the greater intelligence value of a complementary imagery/intelligence report product, vice simply an image product.

Photogrammetry

Photogrammetry includes the precise measurement and computation required in imagery analysis. Measurements of objects/targets as they appear on imagery can be used to compute lengths, widths, heights, and imagery scale. Depending upon the IR, the photogrammetric process can be difficult and time-consuming. Vertical images are relatively straightforward and quick to measure, but oblique and panaoramic images will require greater effort, which can degrade timeliness requirements (particularly at tactical levels). Photogrammetry provides information on—

- Vehicle and equipment dimensions as an aid for identification and for technical analysis.
- Building, storage and other facilities, as well as installations' sizes and capacities.
- Bridges, roads, and other LOCs dimensions and compositions.
- Image scales.
- Speed and the direction of movement of targets and other objects.
- Targeting and weaponeering.

Target Analysis

Generally the imagery analyst's first responsibility is the detection and accurate identification of areas and activities for situation development and support to targeting.

Target detection begins with one of two search modes: general and specific. General search is undertaken in response to requests for broad area intelligence and usually involves the analytical examination of the entire image. Such searches should be kept to a minimum. Specific search is undertaken in response to an IR that requires point, strip or route reconnaissance imagery. Its scope and objectives are more limited than general search.

Target identification consists of the interpretation of visual cues or distinctive features of targets/objects detected during collection. The distinctive features are analyzed using the six Ss: size, shape, shadow, shade, surroundings, and signal strength. The depth and scope of the analysis is highly dependent upon the purpose of the analysis and the associated IR time constraints. Target identification may include:

- Determining the OOB and battle damage assessments of threat units and systems at different echelons.
- Identifying both equipment and its intended use by the threat forces.
- Determining the purpose and composition of ports, harbors, waterways, airfields, roadways, railways, and installations.
- Detecting and identifying nonthreat forces and equipment and sensitive targets (e.g., religious facilities).

See appendix I for information on target folders and IMINT support to these.

Exploitation

Satisfying many IRs will require greater imagery exploitation. Such situations include functional analysis of an object, equipment or environmental analysis; previously unknown objects, equipment or modifications, and activities; unusual concentrations of military or nonmilitary personnel or objects; etc.

National Imagery Interpretation Rating Scale

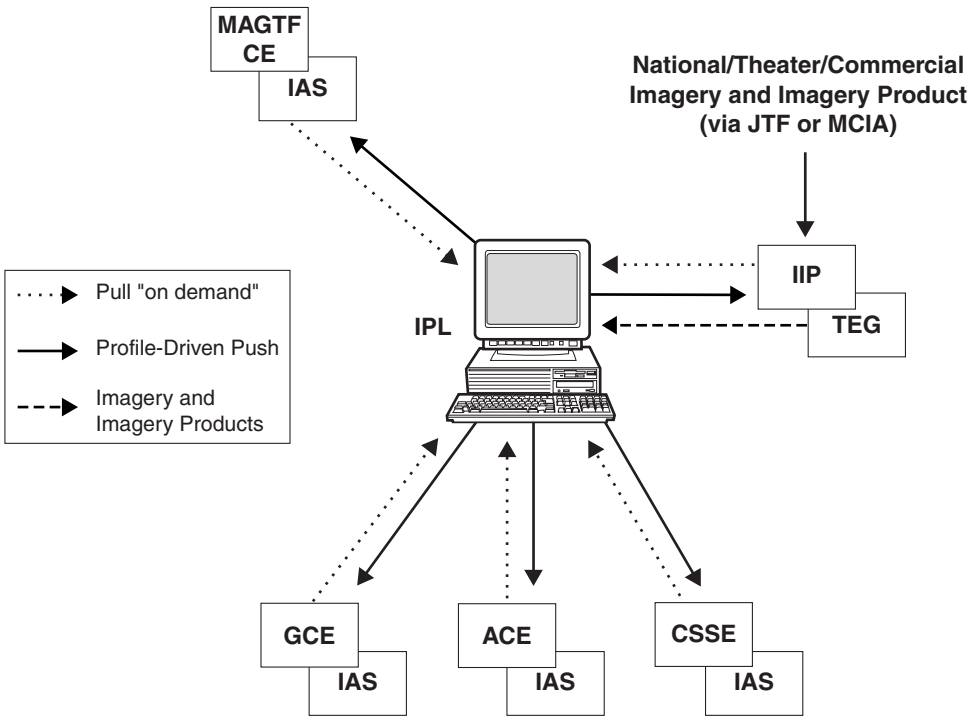
National imagery interpretation rating scale (NIIRS) is used by collection managers as an aid to the identification of the quality of imagery needed to satisfy their IRs. Additionally, imagery analysts use NIIRS to rate the quality and interpretability of acquired imagery. (See appendix B for the visible, infrared, radar, multispectral, and civil NIIRS.)

Imagery Databases

In addition to the development of these products, production also entails the indexing, maintenance, and administration of imagery and IMINT product databases as an aid to future IMINT activities. Imagery analysts must ensure that acquired imagery is incorporated into the MAGTF IPL (see figure 5-18). Generally the IPL will include images in reduced resolution format reviewed by intelligence personnel and other users throughout the MAGTF. Those full-resolution images that meet their IRs can then be downloaded and disseminated.

Dissemination and Reporting

IMINT dissemination planning and management involves establishing dissemination priorities, stipulating dissemination and reporting criteria, selecting



Major subordinate commands (MSCs) down to the regiment/group level will have IPLs with which to store imagery and imagery products and access the Imagery Library Network. IPLs will be populated on the basis of demand-driven "pull" and user-developed profiles ("push").

Figure 5-18. MAGTF Image Product Library.

dissemination means, and monitoring the flow of IMINT reporting. The goal is to deliver IMINT products to the appropriate user in the proper form and at the right time, while concurrently preventing the dissemination of irrelevant products and avoiding information overload. The following paragraphs address the most common considerations for intelligence dissemination planners in developing IMINT dissemination plans.

Identify Dissemination Requirements

When identifying requirements, the four Ws—the who, where, what, and when questions—are a good start for identifying the broad scope of dissemination needs.

The Whos. Commander preferences, standing theater OPLAN/concept plans (CONPLANs), type mission analyses, unit SOPs, TTPs, playbooks, and previous postexercise analyses and lesson learned reports are all key sources for identifying organizations, units, and other elements that the intelligence section must disseminate imagery and IMINT. Identifying and grouping by common imagery and IMINT product requirements by typical command relationship/task organization provide the operational perspective to begin dissemination planning.

- **Internal MEF/MAGTF Headquarters.** Current operations center, future operations center, tactical command echelon (when deployed), force fires coordination center, rear area operations center (when established), civil-military operations center (when established).
- **Subordinate Elements and Unit.** Intelligence sections of the GCE, ACE, and CSSE; other MAGTFs and independent task forces; organic/attached/direct support intelligence and reconnaissance units for whom the MEF retains operational control (via either the SARC, other G-2 sections, direct support teams, and/or direct to the intelligence/reconnaissance units' command posts); and other C2 nodes and facilities, when required (e.g., DASC, enemy prisoners of war compound, rear area operations center, airfield arrival control group).

The Wheres. Usually this will correspond to the location of each identified "who." However, command relationships, the specific operational phase, task organization or other factors may identify other answers to "where" dissemination requirements.

The Whats. With the above information in hand, dissemination planners now seek answers to the "what" of each requirement. Here planners strive to establish or anticipate what type intelligence support—finished intelligence, particular formats—each "who" typically requires to supporting its planning and decisionmaking needs. As with the "who" determinations, commander preferences, standing theater OPLAN/CONPLANs, type mission analyses, unit SOPs, TTPs, and playbooks, and previous post-exercise analyses and lesson learned reports all are key sources for isolating "what" needs and will provide the dissemination SOP foundation. Additionally, planners' research should encompass how differing intelligence resource task organizations affect what requirements and to how the possible "whats" historically have been combined to satisfy the "whos" requirements. Cross-referencing the "who" and "what" answers with the following groupings completes this step:

- Typical stand-alone imagery and IMINT products; and IMINT support to all-source intelligence products.
- Alarm intelligence support (e.g., I&W reports, time-sensitive target of opportunity reporting).
- Preferred level(s) of classified information that the who desires (further subdivided into what they require access to and what they can actually retain on hand).

The Whens. The final dissemination planning information requirement is to determine each "whos" typical or stated "whens". The same sources used to research the previous Ws likewise are recommended for acquiring initial when

answers and baseline planning criteria. However, this factor is arguably the most variable during tactical operations. Key planning considerations include:

- Nature of the requirement (e.g., is it a PIR or in support of another functional information requirement).
- Rapidly assessing the feasibility of satisfying the decisionmaker's or planner's stated LTIOVs (Is intelligence already on-hand? Can organic assets acquire or produce needed intelligence? Will external support be needed?).
- Communications and networks transmission requirements for the who's desired format (voice, text, digital, bulk delivery, etc.)
- Capabilities/current status of MAGTF CIS.

Develop Dissemination Plan

The answers to the four Ws can now be translated into an IMINT dissemination plan. IMINT personnel must maintain close coordination with all G-2/S-2 officers, G-3/S-3 planners, and pertinent intelligence personnel at higher, adjacent, supporting, and subordinate organizations.

Design and Coordinate Architecture. The architecture should be designed schematically so that it depicts organizations, type intelligence systems, and CIS connectivity among the forces' (MAGTF, joint, naval) intelligence collectors/producers and the supported decisionmakers/planners. Since planned architectures must incorporate sufficient flexibility to adjust quickly to changing tactical circumstances, it must depict both primary and alternate pipeline and alarm channels and the demand-pull and supply-push methodologies.

The large data communications bandwidths associated with much imagery dissemination requires close planning and coordination between MAGTF intelligence and CIS planners (see figure 5-19). Also, see appendix J for additional technical information on national imagery transmission format (NITF) compression that is useful when designing and coordinating CIS support to IMINT dissemination.

Establish IMINT Dissemination Procedures. Comprehensive, MAGTF-wide integrated operations/CIS/intelligence procedures are mandatory if intelligence dissemination is to be effective. Answers to the four Ws will provide the initial foundation for development of a MEF's intelligence dissemination architecture and operations. General dissemination procedures should be established for the delivery of IMINT and imagery from the controlling producers or agencies to designated recipients. The precedence of transmission—ranging from routine to flash—should be agreed upon by all involved parties in advance. Audiences should be predetermined as well by defining broadcast parameters (e.g., general or specific). Further, irrelevant intelligence can be better eliminated if reporting regimes, thresholds, and filters are identified early.

Allocate or Obtain Resources. The intelligence officer, in concert with the unit's CIS officer and G-3/S-3, should allocate available resources to accommodate dissemination of the requested IMINT. If resources do not exist to transmit the required information, a request for augmentation from higher headquarters or assistance from lateral units should be initiated immediately. Often it may be necessary to arrange for the delivery of intelligence directly from the producer to the requester if means are in place.

Coordinate. Once IMINT requirements have been identified and the initial plans developed, planners will develop and coordinate detailed dissemination plans. Key considerations include:

- Close coordination among MAGTF CE IMINT, ACE intelligence, and imagery collection units' planners to ensure planned imagery collection missions, specific IRs, routes, and reporting criteria reflect ongoing developments.

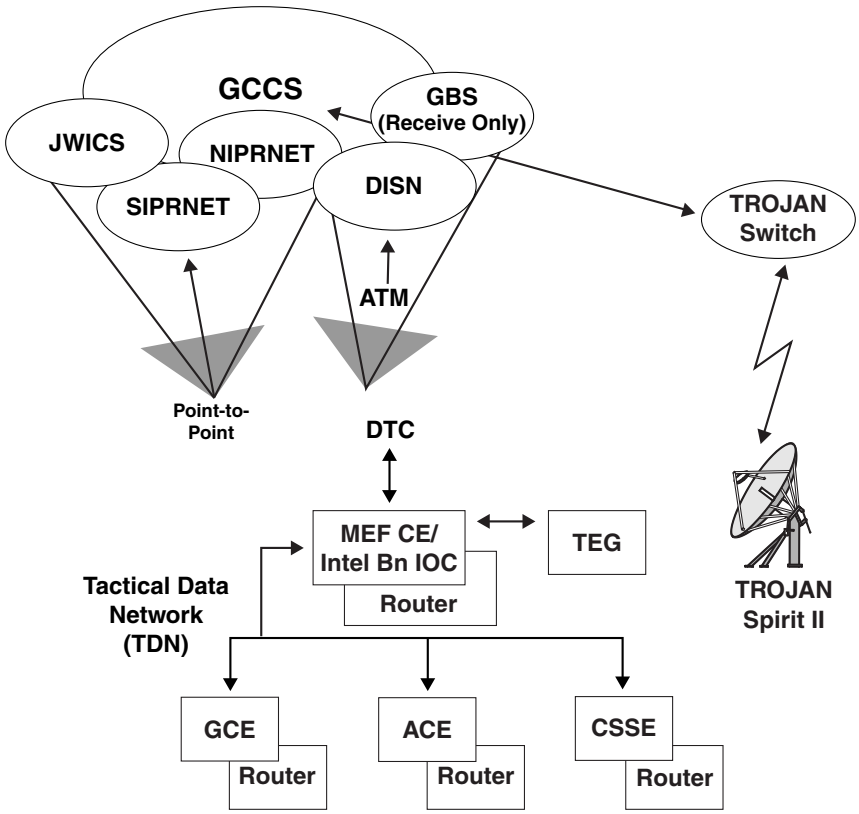


Figure 5-19. Key CIS Pathways for Imagery Dissemination.

- Close coordination between MAGTF CE IMINT planners and subordinate units' intelligence personnel to ensure that they are cognizant of planned imagery collection missions. In addition to voice and e-mail coordination, a useful technique for keeping everyone apprised of planned imagery missions is by including in MAGTF intelligence summaries a detailed paragraph describing specific planned imagery collection missions and associated priorities, collection times, targets, routes, IRs, and primary and alternate reporting channels.

Monitor Execution. Once imagery or IMINT products have begun to be disseminated to the requester, it is important to constantly evaluate the flow of information to determine if the user is satisfied with the quantity and quality of intelligence; and, to ensure that preplanned filters are eliminating circular reporting. Frequent checks with the requester can ensure intelligence utilization and preclude unanticipated demands on the G-2/S-2 staff.

IMINT Utilization

The specific utilization of IMINT is based upon the concept of operations and the imagery application being employed. Commanders, G-2/S-2s, and G-3/S-3s must continuously evaluate IMINT products and reports for timeliness, usefulness, overall quality and responsiveness to stated PIR and IRs, and provide feedback to the MAGTF G-2/S-2 and IMINT planners to improve future IMINT operations. Ultimately, IMINT utilization will provide guidance and determine requirements to support ongoing IR management and supporting IMINT operations.

IMINT Operations Appendix

Guidance for the conduct of IMINT operations comes from many sources. DIA and NIMA issue policies, direction, guidance, and instructions on compliance with national IMINT standards, architectures, and request procedures.

Since MAGTFs will normally be part of a JTF or naval expeditionary force, reference to pertinent combatant, joint force, and fleet commanders' orders, guidance, and IMINT TTPs are necessary to identify unique operating concepts, methodologies, support procedures, and formats. Marine IMINT plans and orders are prepared by the G-2/S-2 (under the staff lead of the ISC and with the assistance of the other G-2 section and intel bn staff officers and commanders) and the COs/OICs of the supporting IMINT units. MAGTF IMINT plans and orders appear as appendix 7 to the intelligence annex of the MAGTF operation plan or order and will focus on internal MAGTF IMINT requirements, operations, and TTP.

Appendix 7 (Imagery Intelligence) to annex B (Intelligence) to an OPLAN or OPORD will provide detailed planning and direction for the conduct of MAGTF IMINT operations. The ISC is responsible for its development. It will be prepared consistent with format outlined in the JOPES, tailored as necessary consistent with the situation and the MAGTF's needs. (See appendix K for a sample IMINT operations appendix format.) The IMINT operations appendix should include friendly IMINT forces to be used, including:

- Personnel augmentation requirements.
- IMINT units of adjacent or other theater forces and support expected.
- Joint force maritime component commander (JFMCC), naval task force and/or amphibious force IMINT elements that provide support to the LF in amphibious operations.
- Pertinent IMINT capabilities and support from the JTF headquarters, combatant command's JIC/JAC, and other component commanders/task forces within JTF operations.
- Planned arrangement and employment of external IMINT support, including special collection, production, dissemination, and CIS.
- Establishment of coordinating instructions for the planning and control of IMINT operations to include the technical support expected from higher headquarters.
- Tasking of MAGTF IMINT elements.
- IMINT production, priorities, and plans.
- IMINT dissemination priorities and plans, to include CIS support to the MAGTF IMINT effort.
- IMINT unique equipment/logistics requirements.

IMINT Plans within Other Portions of Annex B

In addition to appendix 7, there are other portions of annex B that IMINT provides critical contributions or that provide critical operational and intelligence integration plans pertinent to IMINT operations.

Appendix 11 (Intelligence Estimate)

Once a basic understanding of the mission, AO, threat and other pertinent matters is known, it is necessary to view the situation through the adversary's eyes and provide this intelligence assessment to all MAGTF commanders and planners. The intelligence estimate is the principal comprehensive intelligence product that does this. The intelligence estimate seeks to accomplish a number of critical tasks: to state conditions of the area of operations that exist and indicate the effect of these conditions on enemy capabilities and the assigned mission, and assess the estimated effects of these conditions on both enemy and friendly capabilities and operations; to provide basic and current intelligence on threat forces compositions, organizations, strengths, dispositions, locations, activities, C2, logistics, and equipment; to provide an assessment of each en-

emy capability (attack, defend, delay, reinforce, withdraw), to include strengths and vulnerabilities, indicators that point to possible adoption of the capability, and estimates of the effects the enemy's adoption of each capability will have on the accomplishment of the MAGTF's mission; and, finally, intelligence conclusions of the likelihood of each capability being adopted by the enemy (generally listed from the most to least probable) and its associated center of gravity and vulnerabilities and estimated exploitability of these by the MAGTF. The intelligence estimate is an all-source intelligence product that will contain substantial input from IMINT and usually supported by extensive imagery. Additionally, it is where the following intelligence studies will be found, each requiring substantial IMINT and imagery support:

- Tab A, Tactical Study of Terrain.
- Tab B, Beach Studies.
- Tab D, Airfield Studies.
- Tab E, HLZs, and Drop Zones Studies.
- Tab F, Port Studies.
- Tab G, Lines of Communications Studies.
- Tab H, Order of Battle Study.
- Tab I, Survival, Evasion, Resistance, and Escape Safe Areas.

The intelligence estimate and supporting studies will be updated periodically (or new ones developed) throughout an operation, generally through all-source intelligence reports and summaries (again, each will usually have substantial input from IMINT and supporting imagery). The intel bn commander/ISC, through the commander's P&A cell OIC, is responsible for the analysis underlying and preparation of the intelligence estimate and subsequent reports.

Appendix 14 (Reconnaissance and Surveillance Plan)

The reconnaissance and surveillance (R&S) plan is a key tool developed to coordinate and integrate MAGTF R&S operations. Specifically, it provides guidance and orders for establishing and conducting ground reconnaissance, aerial reconnaissance, UAV operations, and remote sensor operations. The R&S plan will generally be developed by the SARC OIC, under the supervision of the intel bn commander/ISC and the CMDO, with the assistance of senior IMINT and R&S planners from force reconnaissance company, UAV squadron, and the ground sensor platoon (GSP). In particular, the following two tabs to the R&S plan appendix require extensive support from IMINT planners.

Tab C, Unmanned Aerial Vehicle Plan

This tab provides detailed intelligence orders, guidance and instructions for MAGTF UAV operations. Responsibility for its development rests with the SARC OIC, assisted by UAV squadron and imagery planners. Its specific content and formats will be mission and situation dependent. It will include information on UAV sortie routine and surge capabilities; preplanned point, route, strip, and area reconnaissance missions; UAV squadron C2 nodes locations; allocation and capabilities of squadron elements (e.g., RRS team assignments and missions); and other similar information. Although it may include tentative planning information on specific PIR and IRs supported as well as type imagery desired, usually this information will be too perishable; instead, when developed it will be incorporated in subsequent specific intelligence mission orders. (See appendix L for a recommended format for a MAGTF UAV plan.)

Tab D, Aerial Imagery Plan

This tab provides detailed intelligence orders, guidance, and instructions for the conduct of MAGTF aerial imagery operations. Responsibility for its development rests with the SARC OIC, assisted by imagery planners. Its specific content and formats will be mission and situation dependent. Generally it will include information on ACE imagery capable aircraft and systems capabilities and sortie routine and surge capabilities; preplanned point, route, strip and area reconnaissance missions; key C2

nodes locations; allocation and capabilities of squadron elements; and other similar information. Although it may include tentative planning information on specific PIR and IRs supported as well as type imagery desired, usually this information will be too perishable. When developed it will be incorporated in subsequent specific intelligence mission orders. (See appendix M for a recommended format for a MAGTF aerial imagery plan.)

Appendix 16 (Intelligence Operations Plan)

This appendix may be developed depending upon the complexity and scope of MAGTF operations and supporting intelligence operations (to include IMINT). It will provide additional guidance not already covered in SOPs for planning and direction of all-source intelligence and CI operations; and for intelligence C2, C2 nodes and facilities, and supporting CIS. It will also identify priority and unique requirements and procedures for the integration of MAGTF intelligence operations with MAGTF C2, maneuver, fires, logistics, and force protection operations; and the integration and interoperability of MAGTF intelligence operations with naval, JTF, theater, national and non-US intelligence operations. The following separate tabs may be included.

Tab A, Intelligence Collections Plan

Provide guidance for executing and managing collection activities not otherwise covered by regulation or SOP, including reconnaissance operations, equipment status, reports, unique intelligence disciplines requirements, and other specialized forms of collection activity to support the plan. Provide guidance on both routine and time-sensitive reporting of collected intelligence information by all collection sources to be employed in support of the plan.

Tab B, Intelligence Production Plan

Identify the intelligence production objectives and effort, including any intelligence and CI products, required to support the OPLAN. Include details of management of intelligence production requirements along with guidance on intelligence production and data bases, forms/formats for intelligence products, production schedules, intelligence products and reports distribution, etc. Include as appropriate requirements and guidance for the following: I&W, support to targeting, combat assessment (to include BDAs), and force protection.

Tab C, Intelligence Dissemination Plan

Stipulate the requirements, means, and formats for disseminating intelligence reports and products (e.g., units responsible for each, periods covered, distribution, timelines standards). Establish the supporting intelligence communications and information systems plan and the supporting procedures and criteria to satisfy expanded requirements for vertical and lateral dissemination of routine and time-sensitive intelligence products and reports. Address voice, network, courier, briefings, and other communications methods, to include point-to-point and alarm methods. Establish alternate means to ensure that required intelligence will be provided to subordinate and supported units. Provide guidance regarding intelligence and information security, to include the dissemination of sensitive compartmented information within the force and the releasibility of intelligence to non-US forces.

Tab D, Intelligence Communications and Information Systems Plan

Provide any specific instruction necessary regarding the establishment, operation, and maintenance of intelligence and pertinent supporting CIS resources and databases, to include those dedicated to intelligence operations as well as multipurpose MAGTF CIS resources used for intelligence purposes.

Note: This tab may be consolidated with Tab C.

Tab E, Intelligence Reports

Provide any instructions necessary regarding intelligence reports, both all-source and single discipline.

Appendix 17 (Support to Survival, Evasion, Resistance, and Escape)

The support to survival, evasion, resistance and escape (SERE) appendix provides guidance, procedures, intelligence products and orders for intelligence support to MAGTF SERE preparations and operations. A variety of intelligence products are developed to support MAGTF SERE readiness. Together with Tab I (Survival, Evasion, Resistance, and Escape Safe Areas) to Appendix 11 (Intelligence Estimate) these constitute the standard SERE support products. The P&A cell OIC is responsible for preparing these products. IMINT and, critically, imagery provide key support to each SERE support intelligence product. These include:

- SERE guides and bulletins. They provide basic information to help an individual survive, successfully evade and, if captured, resist enemy interrogations. The guidelines and bulletins cover an entire country or region and provide information on topography, hydrography, food and water sources, safe and dangerous plants and animals, customs and cultures, recognition of hostile forces, resistance techniques, and other types of information.
- Select areas for evasion (SAFE) area intelligence descriptions (SAID). SAIDs provide essential intelligence concerning specific SAFEs to assist evasion and resistance planners and potential evaders in planning and conducting recovery operations.
- Evasion and recovery (E&R) studies. E&R studies are similar to SAIDs. They differ in that not all conventional selection criteria for SAFE areas can be met because of current political, military or environmental factors prevailing within the area.

APPENDIX A. IMAGING SENSORS

Optical Cameras

Optical cameras detect and record electromagnetic radiation within the visible light and near-infrared portions of the electromagnetic spectrum. The operation principles are the same as for a common box camera. There are three types of optical imaging systems—vertical, oblique, and panoramic.

Vertical

The optical axis of the camera is approximately perpendicular to the surface of the earth (see figure A-1). Vertical imagery is ideal for performing terrain analysis, beach studies, and HLZ studies.

Oblique

Oblique imagery is obtained by imaging the ground at an angle to the vertical. The optical axis of the sensor is intentionally directed between the horizontal and the vertical. This axis can provide left or right oblique coverage. Oblique imagery requires oblique metrics, and is also ideal for observation at canopy baseline.

There are two standard types of oblique imagery, high and low. High oblique imagery (see figure A-2 on page A-2) will include the horizon, while low oblique imagery (see figure A-3 on page A-2) will not. Because of the angle, high oblique imagery covers a larger area than low oblique. Oblique imagery is referred to as left or right oblique or forward looking, based on the look angle in respect to the platform.

Panoramic

Panoramic imagery is taken with a special camera that is able to scan a wide area. The optical axis of the camera utilizes a system of optics that can scan

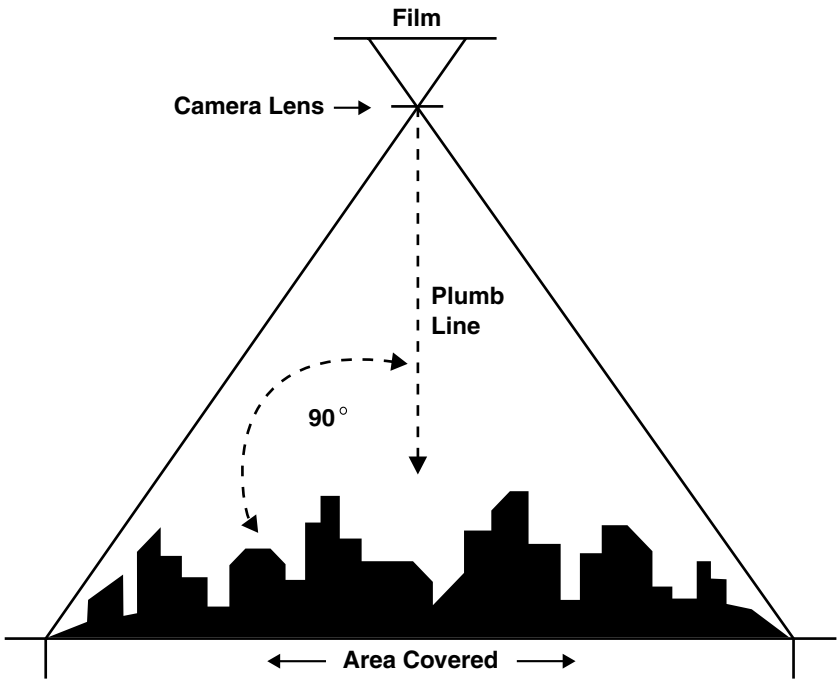

Figure A-1. Relationship of a Vertical Aerial Image with the Ground.

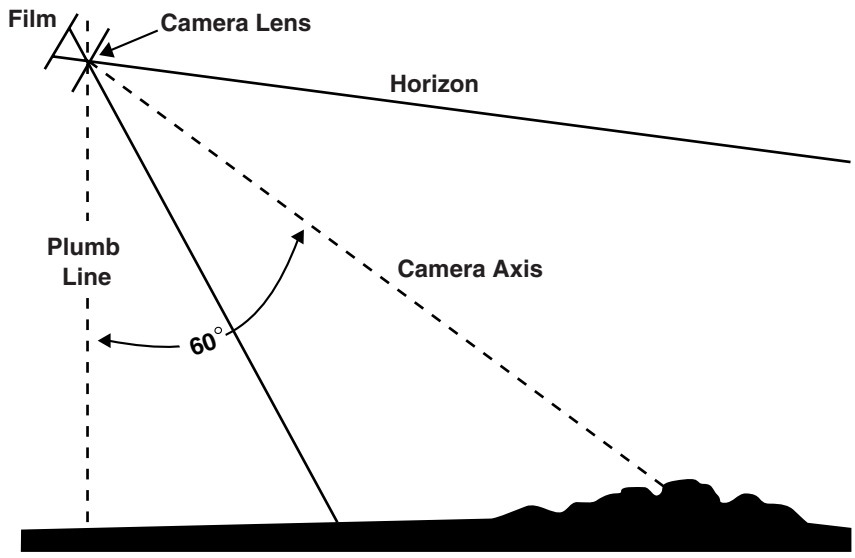

Figure A-2. Relationship of High Oblique Photograph to the Ground.

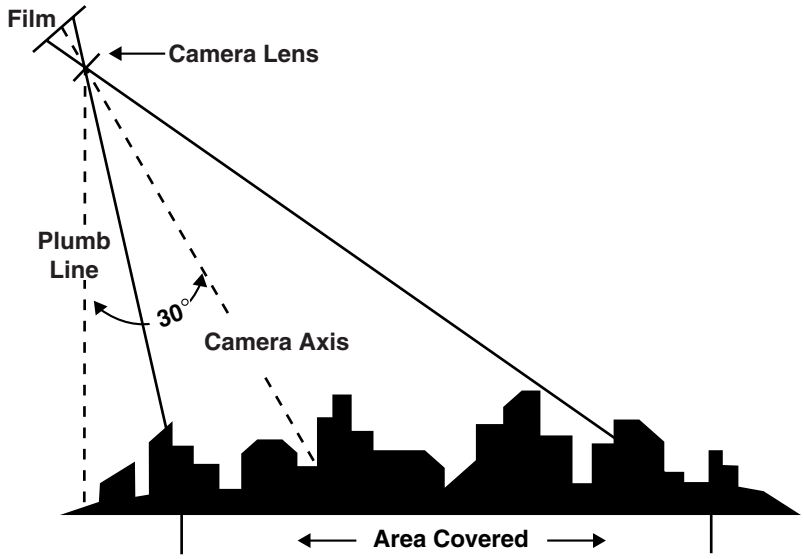

Figure A-3. Relationship of Low Oblique Imagery to the Ground.

an area from 0 to 180 degrees. There are two types of panoramic imagery, low and high.

- Low panoramic imagery (see figure A-4) is taken at low altitudes and scans a wide angle that includes the horizon at either side of the aircraft flight path.
- High panoramic imagery (see figure A-5) is taken at high altitudes with a smaller scan angle.
